ICF International. 2010. West Sacramento Levee Improvements Program 408 Permission Environmental Impact Statement/Environmental Impact Report. Draft. May. (ICF 00875.07.) Sacramento, CA. Prepared for U.S. Army Corps of Engineers and West Sacramento Area Flood Control Agency, Sacramento, CA.

Executive Summary

Approach to the Executive Summary

This executive summary is intended to provide a concise overview of the EIS/EIR for at-a-glance convenience. As such, EIS/EIR content is used verbatim to the maximum extent possible. The heading structure and titles are consistent between the executive summary and EIS/EIR to facilitate easy reference to EIS/EIR sections. The executive summary contents are limited to Chapter 1 (Introduction), Chapter 2 (Alternatives), and a table of environmental effects.

Chapter ES.1 Introduction

The West Sacramento Area Flood Control Agency (WSAFCA) is proposing the West Sacramento Levee Improvements Program (WSLIP or the program) to improve the levees in Yolo and Solano Counties that protect the city of West Sacramento.

To protect human health and safety and prevent adverse effects on property and its economy, the City of West Sacramento (City), as part of WSAFCA, and in partnership with the California Department of Water Resources (DWR), embarked on a comprehensive evaluation of the condition of the levees protecting the city in 2006 (HDR, Inc. 2008). The results of the comprehensive evaluation revealed several deficiencies that require substantial improvements to meet current flood protection standards.

To implement the proposed improvements, WSAFCA is requesting permission from the U.S. Army Corps of Engineers (USACE) pursuant to Section 14 of the Rivers and Harbors Act of 1899 (Title 33 of the United States Code [USC], Section 408, [33 USC 408]), hereinafter referred to as Section 408, for the alteration of the Federal flood control project; authority under Section 404 of the Federal Clean Water Act (CWA) (33 USC 1344) for the placement of fill or dredged material into jurisdictional waters of the United States; and authority under Section 10 of the Rivers and Harbors Act (33 USC 403) where work would be performed in, under, or over navigable waters.

ES.1.1 Document Purpose and Structure

ES.1.1.1 Document Overview

This document is a joint program and project Environmental Impact Statement/Environmental Impact Report (EIS/EIR) and is intended to satisfy the requirements of NEPA and the California Environmental Quality Act (CEQA) for disclosing environmental effects and recommended mitigation measures related to a proposed action and alternatives prior to making a decision on project approval. A "joint" EIS/EIR means that the NEPA lead agency (USACE) and the CEQA lead agency (WSAFCA) are each making a decision on a proposed action and have agreed to analyze the effects of that action in the same environmental document.

USACE is the lead agency preparing this EIS for the purposes of compliance with NEPA. USACE has determined that its involvement in the WSLIP, including its authority over alterations to Federal project levees, requires compliance with NEPA and preparation of an EIS.

WSAFCA is the lead agency preparing this EIR for the purposes of compliance with CEQA. WSAFCA is a Joint Powers Authority created in 1994 through a Joint Exercise of Powers Agreement by the City, Reclamation District 900 (RD 900), and Reclamation District 537 (RD 537).

ES.1.1.2 NEPA and CEQA Requirements

This document is a combined program and project EIS/EIR. The WSLIP is a program of levee improvements that will be implemented over 10 to 15 years, perhaps longer, with reach- or deficiency-specific components that are proposed for implementation in the short term (as soon as 2011). A program EIS/EIR analyzes the broad environmental effects of a program with the acknowledgment that more detailed analysis may be required for components of the program when those components are proposed for implementation and greater specificity is known. Program review provides a forum for discussing combined and cumulative effects of individual projects (projects both internal and external to the program), thereby avoiding segmentation. Two of the WSLIP components are proposed for construction as soon as 2011, and details are sufficiently developed to enable a site-specific environmental analysis at a level of detail sufficient for USACE and WSAFCA to support a decision of approval. Therefore, the program and project analyses are being combined into one document to communicate the program and project context in a transparent manner, disclose available information, and facilitate efficient analysis and review.

USACE and WSAFCA have determined that this joint EIS/EIR is the most appropriate means to comply with both NEPA and CEQA because of the need to coordinate among Federal and state agencies, and the need to complete environmental review as expeditiously as possible.

As described in 1.6.1.1.2, USACE is preparing a West Sacramento General Reevaluation Report (GRR). As the GRR is not scheduled for completion until 2012 to in turn allow improvements in successive years, the WSLIP is being advanced by WSAFCA to facilitate early implementation projects (EIPs) (described in 1.5) to more immediately address flood risk before the GRR is complete. The WSLIP program evaluation and EIPs are intended to be consistent and compatible with the final West Sacramento GRR. Except for EIPs constructed in advance of the GRR, the WSLIP improvements will be substantially implemented through the GRR once in place. The GRR will include NEPA review via an EIS independent of this WSLIP EIS/EIR; however, the documents are being coordinated for consistency and efficiency.

ES.1.1.3 Application of NEPA and CEQA Principles and Terminology

For this environmental evaluation, the more rigorous of the two laws was applied in cases in which NEPA and CEQA differ. In some cases in this document, both NEPA and CEQA terminology are used, as in Chapter 1 where the project purpose and need and project objectives are discussed. The terms *environmental consequences, environmental impacts,* and *environmental effects* are considered synonymous in this analysis, and *effects* is used for consistency.

Technical terms used in the EIS/EIR are typically defined in their first instance of use in the text. A list of acronyms and abbreviations follows the Table of Contents. An index follows Chapter 10.

ES.1.1.4 Document Organization

The document contains an introductory chapter, including the purpose and need, an alternatives chapter, chapters on program- and project-level analyses, and supporting documents.

ES.1.1.5 Resource Analysis Structure

The resource sections in Chapter 3 contain the affected environment and environmental consequences analysis (outlined in detail below) at the program level. Chapters 4 and 5 contain the project-level analysis.

- Introduction
  - Sources of Information
- Affected Environment
  - Regulatory Setting
  - Environmental Setting
- Environmental Consequences
  - Assessment Methods.
  - Determination of Effects
  - Effects and Mitigation Measures

Table ES-1 provides a key for relating the effect findings by relative severity (increasing in degree of adversity to the environment).

Table ES-1. Key to Effect Findings (by increasing adversity)

Finding
Beneficial
No Effect
Less than Significant
Significant
Significant and Unavoidable

ES.1.2 WSLIP Regional Setting and Study Area

The regional setting of the WSLIP is the Sacramento River Flood Control Project (SRFCP), beginning as far north as Redding, California, and extending south to the Sacramento–San Joaquin River Delta (Delta) (Figure 1-1). For the analysis of effects (direct, indirect, or cumulative), the regional context of the SRFCP is taken into consideration.

The WSLIP study area refers to the area that would be protected by the proposed levee improvements, including the city of West Sacramento itself and the lands within WSAFCA's boundaries, which encompass portions of the Sacramento River, the Yolo Bypass, the Sacramento Bypass, and the Sacramento Deep Water Ship Channel (DWSC). The flood protection system

associated with these waterways consists of over 50 miles of levees in RD 900, RD 537, DWR's Maintenance Area 4, and the DWSC (Figure 1-2). These levees completely surround the city with the exception of intersecting waterways. For the purposes of this program, the levees surrounding the city have been divided into nine subreaches, as shown on Figure 1-2. These reaches are described in detail in Section 1.2.1, WSLIP Study Reaches and Potential Construction Footprint.

The city of West Sacramento is located in eastern Yolo County at the confluence of the American and Sacramento Rivers. The city lies within the natural floodplain of the Sacramento River, which bounds the city along the east. It is made up of reclaimed land protected from floods by levees and the Yolo and Sacramento Bypass systems. These bypasses divert floodflows around the city to the west. In addition to the area within the city limits (in Yolo County), the study area partially extends into Solano County on the extreme southwestern edge along the DWSC. Therefore, resources in Solano County have the potential to be affected by the WSLIP and these effects are described on a resource-specific basis.

The DWSC and barge canal bisect the city into two subbasins, separating the developing Southport area from the more established neighborhoods of Broderick and Bryte to the north (City of West Sacramento 2000). The DWSC provides a navigable passageway for commercial shipping to reach the Port of West Sacramento (formerly Port of Sacramento) from the Pacific Ocean via the San Francisco Bay, Delta, and connecting waterways.

The area that would be protected by the WSLIP—the city of West Sacramento—is the downstream-most metropolitan area within the SRFCP, along with the city of Sacramento across the Sacramento River on the left bank. *Note: All levees, reaches, and landmarks are referred to using river navigation terminology. Left bank and right bank refer to locations when facing downstream in the direction of flow.* The downstream location of the study area is important relative to other flood risk reduction projects occurring upstream within the SRFCP, namely, the American River Common Features Project, Natomas Levee Improvement Program, projects undertaken by the Three Rivers Levee Improvement Authority, the Sutter Basin Project, and the Yuba Basin Project (Figure 1-3). These and other projects are described under Section 1.6, Related Actions, Programs, and Planning Efforts.

The potential construction footprint is shown in Figure 1-4.

ES.1.3 Levee Problems and Flood Management Deficiencies

ES.1.3.1 Overview of Levee Failure Mechanisms and Deficiencies

The City engaged a consultant engineering team, led by HDR, Inc., to prepare a problem identification report to determine the type, location, and severity of deficiencies in the WSAFCA flood management system. In simple terms, floods typically occur from levee failure mechanisms and deficiencies such as when:

- water overtops a levee (inadequate levee height);
- water moves through the levee structure (through-seepage);
- water moves under the levee structure (under-seepage);

- levees slopes are overly steepened or levees have inadequate substance to resist floodwaters or other forces (slope stability and geometry);
- water carries soil away from the levee slope (erosion); and
- vegetation and other encroachments, such as structures, impede levee operations and maintenance (non-compliant vegetation and levee encroachments).

These failure mechanisms and deficiencies are summarized below for each of the nine reaches in the study area (Table ES-2). Figure 1-14 illustrates the typical deficiencies.

Table ES-2. Summary of Levee Deficiencies by Reach

Study Reach	Inadequate Levee Height	Through-Seepage	Under-Seepage	Slope Stability and Geometry	Erosion	Non-Compliant Vegetation
Sacramento River North Levee	✓	✓	✓	✓	✓	✓
Sacramento River South Levee	✓		✓	✓	✓	✓
Port North Levee	✓			✓		✓
Port South Levee	✓		✓	✓		✓
South Cross Levee	✓	✓	✓	✓		✓
DWSC East Levee		✓	✓	✓	✓	
DWSC West Levee	✓	✓	✓		✓	✓
Yolo Bypass Levee	✓	✓	✓	✓	✓	✓
Sacramento Bypass Levee		✓	✓	✓		

ES.1.4 WSLIP Purpose and Need

ES.1.4.1 Purpose, Approach, and Objectives

The purpose of the WSLIP is to achieve a minimum of 200-year flood protection for the entire city by improving the approximately 50 miles of levees protecting West Sacramento. A 200-year flood is a flood that has a 0.5% chance of occurring in any given year, or annual exceedance probability (AEP).

The approach to meet this purpose is to provide a comprehensive evaluation of the entire levee system that protects the city, develop recommended strategies for improvement, and provide a basis for partnerships with Federal and state agencies to implement improvements that meet the flood protection and compatible recreation and open space goals. The objectives under this purpose and approach are to:

- construct levee improvements as soon as possible to reduce flood risk as quickly as possible;
- construct improvements that are politically, socially, economically, and environmentally acceptable;
- provide recreation and open space elements for the city that are compatible with flood improvement actions; and
- ensure continuing Federal assistance for levee repairs and maintenance.

ES.1.4.2 Need for Action

Five needs have been identified for the WSLIP.

- Study results from the comprehensive levee evaluation have shown that the levees protecting the city need improvements to reduce the current level of risk to human health and safety, property, and the adverse economic effect that serious flooding would cause.
- Study results further have shown that the levees in WSAFCA's area are deficient when compared against current Federal standards. Action is needed to bring them up to current standards in order to maintain eligibility for Federal emergency management assistance. Those improvements are necessary to meet FEMA's minimum acceptable level of flood protection (commonly referred to as the 100-year flood) as specified by the National Flood Insurance Program (NFIP). (HDR, Inc. 2008.)
- As required by Senate Bill (SB) 5 (signed by Governor Schwarzenegger in October 2007), the Central Valley Flood Protection Board (CVFPB) must adopt a Central Valley Flood Protection Plan (CVFPP) by July 1, 2012. The CVFPP will require a 200-year level of flood protection for urban areas by the year 2025. Levee improvements are necessary to meet that requirement.
- As a growing community, the City has recreation and open space needs and goals that are unmet. Surrounding waterways represent not only an element of flood risk but also great opportunity for water-based recreation and public open space. Flood protection improvement elements typically underlie or are adjacent to proposed recreation elements that are part of the City's planning documents. There is a need to provide West Sacramento residents with recreation elements that are compatible with flood protection improvements.
- As described in Section 1.2, WSAFCA's area is the downstream-most metropolitan area in the SRFCP. As other projects have been implemented or improvements are being planned to reduce risk and increase flood protection for upstream communities, there is concern that the performance of the SRFCP needs to be evaluated comprehensively to ensure that the individual projects are kept in balance, that effects among the projects are being evaluated, and that risk is not being transferred between communities. The WSLIP represents an important subarea of the SRFCP and merits such study, heightened by West Sacramento's downstream location.

To further demonstrate the need for action, details about West Sacramento's flood risk and the consequences of levee failure in West Sacramento are described in the Alternatives chapter (2.4.2.2, Consequences of Levee Failure). Additional context for the objectives of, purpose of, and need for the WSLIP can be found in Chapter 1.

ES.1.5 WSLIP Background

ES.1.5.1 Regional Flood Management History

The SRFCP was authorized by Congress in 1917. The SRFCP was the major project for flood control on the Sacramento River and its tributaries (Figure 1-1). It was sponsored locally by The Reclamation Board of the State of California (Reclamation Board, reauthorized in 2007 as the Central Valley Flood Protection Board [CVFPB]) and was the first Federal flood control project constructed outside the Mississippi River Valley. Currently, there are several major flood risk

reduction projects being planned or implemented within the SRFCP area (Figure 1-3). Projects relevant to the WSLIP are discussed in further detail under Section 1.6, Related Actions, Programs, and Planning Efforts, below.

Prior to European settlement in the mid-19th century, the floodplain of the Sacramento River in the 150 miles between the city of Redding and the Delta varied from 2 to 30 miles wide and annually covered more than 1 million acres. Low, discontinuous levees were built by individual landowners from the 1840s to the 1890s. Those levees concentrated floodflows and contributed to problems that were worsened by upstream hydraulic mining in the Sierra Nevada foothills in the late 1800s. With the authorization of the SRFCP, USACE and the State of California began managing the project as a "regional system," constructing improvements to approximately 1,100 miles of levees and creating bypasses and floodways.

Although the flood control structures have been extensively improved and upgraded since construction, the underlying foundation of most of the levees and channels pre-dates any state or USACE involvement and still retains the original materials that include dredged riverbed sands, soil, and organic matter. At the time of the SRFCP authorization in 1917, the areas being protected by the levees were primarily agricultural with minimal improved infrastructure such as railroads and highways. Many of these areas are now heavily urbanized and densely populated, including the city of West Sacramento.

The Federal government maintains oversight but has no ownership of or maintenance responsibilities for the Federal levee system, except for few select features that continue to be owned and operated by USACE. Considering these exceptions, the great majority of levees, channels, and related flood control structures are owned, operated, and maintained by local levee and reclamation districts (at the county and sub-county level) and the State of California. Most of the levee and reclamation districts existed prior to the SRFCP authorization in 1917 and have been carrying out maintenance responsibilities. Today, however, most of the levee districts are substantially underfunded and unable to maintain the system to meet current Federal standards. The Federal government can participate in improvements to the Federal levee system in partnership with a local sponsor (the state and/or levee and reclamation districts). The levees surrounding the city are maintained by RDs 537 and 900 and DWR's Maintenance Area 4.

In recent decades, a number of evaluations of levee conditions, as well as repair and reconstruction efforts, have occurred. Some have been in specific response to damage resulting from particular flood events; others have been in response to general levee deterioration over time and deferred maintenance.

In 1986, 1995, and 1997, there were record flood stages in the Sacramento region. As a result, USACE evaluated the level of flood protection in the study area with updated hydrology and levee analysis. It was determined that the risk of flooding from the Sacramento River and its tributaries ranges from 1 in 25 (25-year) to more than 1 in 100 (100-year) each year (or 4% to 1% probability), depending on the location.

ES.1.5.2 Local Flood Management History

Consistent with much of the Sacramento Valley as described above, the levees protecting West Sacramento were initially constructed in the 1840s to 1890s. They later became part of the SRFCP authorized by Congress in 1917. These levees have been strengthened and maintained through

several subsequent projects in partnership between USACE, the State of California, the City, and the agencies that maintain the levees.

Recent milestones in the flood management context of West Sacramento include the following activities.

- In 1992, the USACE concluded that the levees along the Sacramento River and Yolo Bypass did not provide protection from a 100-year flood event.
- In 1993, a flood control project was completed as part of the Sacramento Urban Area Levee Reconstruction Project. This project placed a stability berm and related features to address through-seepage along the entire length of the Sacramento River levee bordering the Southport area (referred to in the WSLIP study area as the Sacramento River South Levee).
- In 1994, the City and reclamation districts formed a Joint Powers Authority, WSAFCA, to coordinate, fund, and construct major flood protection improvements that were beyond the means of the individual entities (City of West Sacramento 2000).
- In 1995, WSAFCA formed an assessment district to fund the local cost share for the West Sacramento Project. This project was part of the Federal Sacramento Metropolitan Area Project authorized by the Water Resources Development Act of 1996 (WRDA), as described above. The WSAFCA assessment funded geotechnical and engineering investigations of the Sacramento River levees and the southern boundary cross levee in the Southport area (PB 2007). The West Sacramento Project was designed to provide the city with a greater than 200-year level of protection.
- During the 1997 record flood stage event, the levees surrounding the city sustained minor damage. As design work was nearing completion on the West Sacramento Project, under-seepage was noted along the Sacramento Bypass levee.
- In 1998, stability issues became apparent along a levee maintained by RD 537 just north of the Southern Pacific Railroad tracks.
- In 2002, the West Sacramento Project was substantially completed. This project involved raising more than 1 mile of the south levee of the Sacramento Bypass by up to 5 feet and raising 4.5 miles of the Yolo Bypass levee by up to 5.5 feet.
- As described above, in May 2007, property owners in West Sacramento approved a new annual parcel assessment to provide funding for flood improvements, facilitating the WSLIP study.
- In 2008, WSAFCA completed an EIP known as the I Street Bridge EIP. This EIP improved a critical section of levee in the redevelopment area along the riverfront of the city to reduce flood risk to public safety, private property, and public infrastructure. The EIP improved a 475-linear-foot reach of the Sacramento River North Levee of the WSLIP study area to address the problems of through- and under-seepage. This EIP and Section 408 action was expeditiously completed by WSAFCA, the State of California, and USACE.

ES.1.5.3 Local Recreation Needs

The City, as a member agency of WSAFCA, is proposing recreation elements that are compatible with flood improvements to meet recreation needs. For example, the Sacramento River is central to the identity and image of the city, yet opportunities to enjoy it are hampered by lack of safe and accessible public access points. The city is also lacking developed facilities and infrastructure for

dedicated off-street bikeways, environmental interpretation and education, fishing, boating, hiking, and other active and passive outdoor recreation experiences. This situation has been heightened by the recent growth of the local population, demographically influenced by young families and individuals oriented toward outdoor recreation.

The *City of West Sacramento Parks Master Plan* (Parks Master Plan) from 2003 identified several key recreation opportunities for the city that will enable its citizens and visitors to enjoy the resources provided by the Sacramento River and other waterways. The recreation needs relative to the WSLIP are summarized below.

- **Improved water access.** Residents value the water resources available in West Sacramento. They desire improved access to water-related recreation such as fishing, boating, swimming, and passive use (e.g., wildlife viewing and hiking).
- **Recreation corridors and trails.** The residents support corridors for bicycling, walking, and horseback riding.

ES.1.6 Related Actions, Programs, and Planning Efforts

This section lists other flood management activities that comprise the regional planning context for the WSLIP.

- Sacramento Metropolitan Area, California, Feasibility Report (West Sacramento Project)
- West Sacramento General Re-Evaluation Report
- Sacramento River Deep Water Ship Channel Project
- Sacramento Weir Sediment Removal Project
- Central Valley Flood Protection Act
- Natomas Levee Improvements Program
- Sacramento River Flood Control System Evaluation
- Sacramento–San Joaquin Rivers Comprehensive Study
- American River Common Features Project
- Sacramento River Bank Protection Project
- Flood Control and Coastal Storm Emergency Act

ES.1.7 Community Outreach, Agency Coordination, and Issues of Known Controversy

ES.1.7.1 Community Outreach

USACE and WSAFCA have established a proactive multi-media outreach program to communicate the WSLIP. The approach to the outreach program has been to go beyond the guidelines and

requirements of NEPA and CEQA for public noticing to ensure the affected community and other interested stakeholders are informed, engaged, and involved through an accessible, open, and transparent process. Thus far, the outreach program has included more than a dozen actions, including meetings, publications, web-postings, and other community involvement activities.

To date, the results of the outreach program have been very favorable, constructive, and supportive for the WSLIP. The tone and substance of the input has been consistent with the very favorable response for the voter-approved assessment to fund the local share of the WSLIP. Comments received from the public have been considered to refine the project description and the environmental analysis.

A more detailed accounting of the scoping process is provided in Appendix A.

ES.1.7.2 Agency Consultation and Coordination

The WSLIP has been planned in coordination and cooperation with numerous local, state, and Federal agencies. In Chapter 3, the Regulatory Setting for each respective resource describes the compliance with applicable Federal, state, regional and local laws and regulations, including consultation to date with various agencies, such as U.S. Fish and Wildlife Service (USFWS), the National Marine Fisheries Service (NMFS), and the California Department of Fish and Game (DFG), as well as Native Americans.

This EIS/EIR will be used by Responsible and Trustee Agencies to determine the effects of the proposed action.

ES.1.7.3 Issues of Known or Expected Controversy

NEPA requires that project proponents identify issues of known controversy that have been raised in the scoping process and throughout the development of the project. Thus far, no substantial issues have been discovered through public feedback. However, the following potentially controversial issues are anticipated to arise in the conduct of the environmental analysis process.

- Construction-Related Effects
- Property Take and Restricted Property Access
- Restriction of Vegetation on Levees
- Climate Change and Sea-Level Rise

Chapter ES.2
Alternatives

ES.2.1 Introduction

Chapter 2 describes the following elements:

- general information about improvements, including the screening process;

- WSLIP program description for flood and recreation improvements;
- project-level description for two EIPs: CHP Academy EIP and The Rivers EIP; and
- environmental commitments incorporated into the program and project description to be considered in the environmental analysis for all action alternatives.

ES.2.2 General Information about Alternatives

ES.2.2.1 Approach to Alternatives

NEPA and CEQA generally require that an EIS and EIR (respectively) consider a range of alternatives that would attain most of the basic project purpose, need, and objectives while avoiding or substantially lessening project effects..

Consistent with NEPA standards, alternatives at the program level are analyzed on an equal, non-preferential basis (i.e., there is no proposed project/preferred alternative) and at an equal level of detail. As required under NEPA and CEQA, a no-action (no-project) alternative has been included to allow comparison of impacts of a range of alternatives including no project implementation.

The alternatives for the program have been developed on a reach-by-reach basis, rather than basin-wide. The alternative levee treatments are not bundled or packaged but rather are evaluated independently at the program level, allowing for flexible combinability at the project level. In describing and analyzing the WSLIP at the program level, the individual flood and recreation improvements function as alternatives for the purposes of this EIS/EIR. In describing and analyzing the EIPs under the WSLIP at the project level, flood and recreation improvements have been packaged into at least two project alternatives for the purposes of this EIS/EIR.

ES.2.2.2 Alternative Screening Process

The alternative screening process includes a pre-program screen, program-level screen, and project-level screen.

ES.2.2.2.1 Pre-Program Screen

Prior to analysis in the EIS/EIR, certain improvements were screened out based on the following criteria:

- geography and jurisdictional authority, and
- ability to meet purpose and objectives.

ES.2.2.2.2 Program-Level Screen

Improvements that passed the pre-program screen are evaluated uniformly against a set of criteria and compared to one another and no action at the program level. The environmental analysis in this EIS/EIR is part of the program-level screen, combined with other planning, engineering, and financial factors, likely to include the following elements:

- ability to address the flood management problem or levee deficiency;

- avoidance, minimization, and mitigation of environmental effects;
- land use compatibility;
- integration of multi-purpose objectives, such as delivery of recreation features that are compatible with flood improvements;
- cost; and
- public feedback, including that discovered during the EIS/EIR process.

ES.2.2.2.3 Project-Level Screen

Beyond the program level, screening criteria are applied to identify reach-specific improvements. While the final criteria are subject to change as the WSLIP develops and the process unfolds, the criteria are likely to include the following elements:

- ability to meet the project objectives (i.e., address the deficiencies) to reduce risk;
- availability of funds;
- scalability of construction;
- real estate requirements;
- land use compatibility;
- permit requirements;
- environmental constraints;
- integration of multi-purpose objectives, such as delivery of recreation features that are compatible with flood improvements;
- evolving technical policy; and
- public feedback, including that discovered during the EIS/EIR process.

ES.2.3 Program-Level Alternatives Considered but Not Carried Forward

Several alternatives to the WSLIP were considered but not carried forward based on the pre-program screening criteria presented in Section 2.2.2.1. These alternatives are listed below.

- Reoperation of Upstream Reservoirs
- Reoperation of Weirs
- Development of Additional Upstream Storage
- Raising Building Pads
- DWSC Closure Structure and Gated Weir

ES.2.4 No Action Alternative

ES.2.4.1 Introduction to No Action

The No Action Alternative serves as a benchmark against which the effects and benefits of the action alternatives are evaluated. The No Action Alternative consists of continuation of current conditions and operation and maintenance practices that reasonably would be expected to occur in the foreseeable future if the WSLIP were not implemented based on current plans and consistent with available infrastructure and community services.

ES.2.4.2 No Flood Improvements Implemented under the No Action Alternative

Under the No Action Alternative, WSAFCA would not implement flood improvements. The levees protecting the city would continue to require improvements to meet FEMA's minimum acceptable level of flood protection. In addition, the associated risk to human health and safety, property, and the adverse economic impact that serious flooding could cause would continue, and the risk of a catastrophic flood would remain high.

ES.2.4.2.1 Consequences of Levee Failure

Assuming that no levee repair or strengthening would occur under the No Action Alternative means that the West Sacramento levee system would remain or become more susceptible to failure as a result of identified deficiencies such as seepage, erosion, inadequate levee height, and slope instability. These conditions could cause portions of the levee system to fail, triggering widespread flooding, extensive damage to the city's existing residential, commercial, agricultural, and industrial structures, and potential loss of life and property. Extensive damage to utilities, roadways, major interstate transportation corridors, and other infrastructure systems would also likely occur.

Flood depth maps prepared for West Sacramento indicate that under a 100-year flood event scenario, inundation levels would range from 1 foot to 15 feet, depending on the local elevation of the land surface. Figure 2-1 shows the ultimate estimated inundation depths for a 100-year flood event.

In 2006, two hypothetical levee failures were analyzed for West Sacramento utilizing 100-year water surface elevations and hydrology. This analysis was performed to assist the City in its flood emergency preparedness planning. One failure was located in the northern part of the city, on the Sacramento River North Levee, and the other was located in the Southport area, on the Sacramento River South Levee (failure locations are shown in Figures 2-2 and 2-3). (Wood Rodgers 2006.)

The analysis indicates that a levee failure on the Sacramento River North Levee during a 100-year event would flood the entire north area with at least 1foot of water within 24 hours, at which point vehicular evacuation would become impossible (a depth of 1 foot is regarded as impassable from the standpoint of vehicular traffic). Certain neighborhoods close to the levee failure would lose access to evacuation routes within three hours of levee failure. Figure 2-2 shows the estimated time to 1-foot inundation depths throughout the northern area. Within3 days, floodwater depths would reach 3to 10 feet, depending on land surface elevation (as shown in Figure 2-1). Floodwaters would flow from north to south, seeking the lowest topographical elevation, and eventually discharge into the DWSC.

The study estimates that floodwaters would begin to spill into the DWSC less than 24 hours after the breach. Modeling indicates that the DWSC could absorb up to 20,000 cubic feet per second (cfs) in discharge flow from waters flooding the north area of the city before overtopping and flooding the Southport area. (Wood Rodgers 2006.)

A levee failure on the Sacramento River South Levee during a 100-year event would flood the entire Southport area with at least 1 foot of water within 24 hours. Jefferson Boulevard, the only vehicular evacuation route for Southport, would be inundated by 1 foot of water within 4 hours, making it impassable. Figure 2-3 shows the estimated time to 1-foot inundation depths throughout the Southport area. Inundation depth could reach 3 feet in 36 hours and 10 feet after three days (Figure 2-1). Floodwaters would flow from east to west, then turn south, collecting at the South Cross Levee. The maximum stage from the floodwater was estimated at elevation 22 feet. The elevation at the top of the South Cross Levee is 21.5 feet. If the South Cross Levee were overtopped, further flooding would occur downstream of the city of West Sacramento. (Wood Rodgers 2006.)

Levee failure and subsequent flooding of the city of West Sacramento would affect the entire city, jeopardizing lives, and would cause substantial damage to structures, contents, and other property such as landscaping and automobiles. As of 2005, a population of 40,439 was living in 15,448 housing units within the city (Sacramento Area Council of Governments 2008a and 2008b). All of these residents could be displaced by a catastrophic flood event. Additionally, the city is home to 30,655 jobs (Sacramento Area Council of Governments 2008c), 734 commercial and industrial structures, 46 public structures and 27 park facilities, which would all be affected by a flood event (HDR, 2009). Environmental and agricultural resources could also sustain major damage in a flood event; 22.6% of the land area within the city is either farmland or open space (City of West Sacramento 2009). If a catastrophic flood event occurred resulting in inundation up to 15 feet, land damages are estimated to be $237,763,648 and structural damages could be up to $1,750 ,118,102 (PB 2007). These values are based on the 100-year event.

A flood event in West Sacramento would also disrupt state and interstate highway, rail, and shipping traffic, causing long-term effects on the region's and the state's economy and ability to move people and goods. West Sacramento has one of the most comprehensive transportation networks on the west coast. Its central geographic location and extensive north-south and east-west highway access has made it a major distribution center. High volumes of truck and passenger traffic pass through the city on Interstate 80 and US-50/Business 80 every day, with truck traffic transporting approximately $63 billion worth of cargo annually through West Sacramento (HDR Engineering 2009). Major transcontinental rail lines passing through the city provide commercial and passenger rail service to all parts of the nation, and the Port of West Sacramento runs domestic and international shipping services (City of West Sacramento 2009). Approximately 9.3 million tons of rail freight valued at approximately $5 billion travels through West Sacramento annually (HDR Engineering 2009). Flooding of this transportation and distribution infrastructure would cut off major statewide and interstate transportation corridors.

ES.2.4.2.2 Future State or Federal Action

Despite the likelihood of state- or Federal-led implementation of repairs, for the purpose of evaluating impacts under the No Action Alternative, the EIS/EIR assumes that the improvements would not occur. Again, as stated above, the No Action Alternative therefore assumes no levee repair or strengthening would be implemented, the purpose and objectives would not be met, and flood risk would continue.

ES.2.4.3 Relationship of Flood Map Modernization to No Action

FEMA is in the process of reevaluating the level of flood protection provided by the levee system protecting the city. The city is currently designated as falling under Zone X, meaning it has less than a 1% chance of flooding in any given year (100-year flood protection). If the city were remapped out of Zone X and into an A, AE, AR, or A-99 Zone, flood insurance would become mandatory for all citizens and businesses that hold federally guaranteed mortgage loans. In addition, Federal and state regulations would prevent or constrain further development in the city, which may further delay levee improvement funding because a flood improvement development fee is incurred for new development.

A change in the flood hazard designation for West Sacramento would interrupt the preferred regional "blueprint" for future growth through 2035 adopted by the Sacramento Area Council of Governments (SACOG) and Valley Vision in 2004. With a change in flood hazard designation, 40,000 new dwelling units and the commercial and industrial developments associated with 50,000 new jobs would need to be redirected to other areas in the region over the next four decades (Sacramento Area Council of Governments 2004).

ES.2.4.4 Levee Vegetation Policy and No Action

While the USACE review and approval process under Section 408 (which this EIS/EIR is part of) is one mechanism for review of WSAFCA's levees relative to recent USACE policy guidance for vegetation on levees, the No Action Alternative would be the same as the WSLIP, meaning the future condition is removal of non-compliant vegetation in any case. At this time no variance is in place and this EIS/EIR analysis assumes no variance would be in place under the No Action Alternative.

ES.2.4.5 Recreation under No Action

The No Action Alternative would also delay implementing elements of the Parks Master Plan, Bicycle and Pedestrian Path Master Plan, and the Sacramento Riverfront Master Plan (SRMP).

ES.2.5 Program-Level Alternatives for Levee and Flood Management Deficiencies

For each deficiency described in Chapter 1, a number of improvements or combination of improvements can be used to attain the level of flood protection desired, summarized in Table ES-3.

Table ES-3. Summary of Levee Improvements and Deficiencies

		Deficiency					
Group	Improvement	Inadequate Levee Height	Through-Seepage	Under-Seepage	Slope Stability and Geometry	Erosion	Non-Compliant Vegetation
Levee Height	Flood wall	✓					
	Levee raise (in place)	✓					
	Levee raise (adjacent)	✓	✓		✓	✓	✓
	Levee raise (full)	✓	✓		✓		
	Closure structure	✓

Slope Stability/ Geometry	Slope flattening		✓		✓		
	Stability berm		✓		✓		
Erosion Control	Rock slope protection				✓	✓	
Other	Setback levee	✓	✓		✓	✓	✓
	Vegetation removal						✓

ES.2.6 Program-Level Alternatives for Recreation

The City, as a member agency of WSAFCA, is proposing recreation and non-motorized transport improvements that are compatible with flood improvement actions to meet recreation needs. These improvements are listed below.

- Trails
- Riverside Parks
- Developed Water Access
- Special Projects

ES.2.7 Summary of Program Improvements by Reach

Based and building on the information presented earlier in this chapter, Table ES-4 summarizes the potential flood and recreation improvements on a reach-by-reach basis.

Table ES-4. Summary of Program Improvements by Reach

		Reach								
Improvement Group	Improvement	Sacramento River North Levee	Sacramento River South Levee	Port North Levee	Port South Levee	South Cross Levee	DWSC West Levee	DWSC East Levee	Yolo Bypass Levee	Sacramento Bypass Levee
Flood : Levee Height	Flood wall			✓	✓		✓			
	Levee raise (in place)	✓	✓		✓		✓	✓

ES.2.8 Project-Level Alternatives

ES.2.8.1 Introduction and Project Phasing

Two EIPs are being analyzed in a parallel process with the WSLIP to address critical areas where the levee deficiency is well-defined and the most suitable treatments are known, applying the project-level criteria presented earlier in this chapter.

At this time, WSAFCA is proposing the EIPs for sites on the Sacramento Bypass and Sacramento River North levee reaches, referred to as the CHP Academy EIP and The Rivers EIP, respectively. These sites have both had observed past performance issues, with evidence of seepage at both sites

(and possible boils at The Rivers). Table ES-5 provides an overview of the deficiencies and upgrades proposed at these sites for flood management. Recreation improvements also are proposed.

Table ES-5. CHP Academy and The Rivers EIP Alternatives

EIP	Program Component	Applicant Preferred Alternative	Alternative B
CHP Academy	Flood	Slurry cutoff wall and waterside slope flattening	Stability berm with interior drain, and relief wells
	Recreation	Paved bike trail, non-motorized access controls	Paved bike trail, non-motorized access controls
The Rivers	Flood	DSM cutoff wall, and landside slope flattening (landside hinge point stationary, kick out toe)	Deep sheet pile wall and landside slope flattening
	Recreation	Paved bike trail, paved pedestrian trail, paved landing, landside levee embankment ramps, interpretive signs, non-motorized access controls	Paved bike trail, paved pedestrian trail, paved landing, landside levee embankment ramps, interpretive signs, non-motorized access controls

ES.2.8.2 CHP Academy EIP

The CHP Academy EIP encompasses approximately 6,500 feet of the Sacramento Bypass Levee, (Figure 2-23). The easternmost 1,200 feet of the waterside slope of the levee (adjacent to the weir) is lined with a concrete cap. This concrete cap prevents the levee from eroding when the weir is open and water is allowed to enter into the Sacramento Bypass from the Sacramento River. A stability berm and an interior drain system installed as part of the West Sacramento Project in 1999 runs the length of the levee on the landside. Deficiencies at this site are through-seepage, geometry, and under-seepage, along with short reaches of instability.

ES.2.8.3 The Rivers EIP

The Rivers EIP area is approximately 4,500 feet long and is located on the Sacramento River North Levee, just north of the confluence of the Sacramento and American Rivers, including part of The Rivers residential development (Figure 2-24). Levee deficiencies at this site include geometry, stability, through-seepage, and under-seepage.

ES.2.9 Environmental Commitments

Environmental commitments are measures incorporated as part of the program and project description, meaning they are proposed as elements of the proposed action and are to be considered in conducting the environmental analysis and determining effects and findings. To avoid and minimize construction-related effects, WSAFCA would implement the following environmental commitments at the program and project levels to reduce or offset short-term, construction-related effects. Measures have been developed for each of the topics below, to be applied in the program- and project-level resource analyses.

- Raptors
- USACE Levee Vegetation Guidance
- Protected Trees and Riparian Trees
- Avoid and Minimize the Spread or Introduction of Invasive Plant Species
- Stormwater Pollution Prevention Plan
- Temporary Visual Barriers between Construction Zones and Residences
- Noise-Reducing Construction Practices
- Temporary Resident Relocation, Property Acquisition, and Compensation for Loss of Business
- Traffic Control and Road Maintenance Plan
- Coordination to Ensure Minimal Overlap in Disturbance to Traffic during WSLIP Construction
- Coordination of Construction Periods with Railroad Service Officials
- Coordination of Construction Periods with the Port of West Sacramento
- Coordination of Construction Periods with CHP
- Notification of Construction Area Closure
- Reconstruction of Affected Formal Park Facilities
- Preservation of Marina and Boat Launch Access
- Minimization of Construction-Related Effects on Navigation
- Approval for Broderick Boat Ramp Closure
- Bentonite Slurry Spill Contingency Plan [1]
- Spill Prevention, Control, and Counter-Measure Plan
- Implementation of Measures to Maintain Surface Water Quality and Groundwater Quality
- Monitoring of Turbidity in Adjacent Water Bodies
- Soil Supply Protection Measures

Effects Summary Table

Table ES-6 is a summary of the effects of the WSLIP, CHP Academy EIP, and The Rivers EIP. The effects that are significant and unavoidable or that are potentially significant and unavoidable, depending on site or project characteristics, are listed below.

- TN-1: Temporary Increase in Traffic Volumes from Construction-Generated Traffic and Potential Degradation of LOS for Roadways in the Program Vicinity

[1]Also referred to as a *frac-out plan*, which addresses the movement of mud toward the surface caused by excessive drilling pressure.

- TN-2: Temporary Road Closures or Restricted Access to Parking on the Levee Crown or Roads That Run Adjacent to the Levee
- TN-10: Temporary Loss of Service to Railroads
- AQ-2: Increase in Construction Emissions to Exceed Applicable Thresholds
- NZ-1: Exposure of Sensitive Receptors to Temporary Construction-Related NoiseNZ-5: Exposure of Sensitive Receptors to Temporary Construction-Related Vibration
- VEG-1: Permanent Loss of Woody Riparian Vegetation from Levee Vegetation Removal
- VEG-2: Potential Loss of Special-Status Plant Populations Caused by Habitat Loss Resulting from Program Construction
- FISH-1: Permanent Loss of Habitat, Including Shaded Riverine Aquatic Cover, for Special-Status Fish Species Resulting from Levee Vegetation Removal
- FISH-2: Loss of Habitat for Special-Status Fish Species as a Result of Construction
- WILD-1: Permanent Loss of Riparian Habitat for Special-Status Wildlife Species as a Result of Levee Vegetation Removal
- WILD-2: Disturbance or Loss of Special-Status Wildlife Species and Their Habitats as a Result of Construction
- SOC-1: Effects on Residents
- VIS-1: Affect a Scenic Vista
- VIS-2: Create a New Source of Light or Glare
- VIS-5: Affect the Existing Visual Character or Quality of the Site and Its Surroundings as a Result of Construction, Operations, and Maintenance
- VIS-6: Conflict with Local Visual Resource Policies
- REC-3: Long-Term Reduction in Quality of Existing Recreation Opportunities in the Levee Corridor
- PUB-1: Damage of Public Utility Infrastructure and Disruption of Service
- CR-1: Effects on Architectural (Built Environment) Resources and Cultural Landscapes
- CR-2: Change in the Significance of an Archaeological Resource
- CR-3: Disturbance of Native American and Historic-Period Human Remains

Table ES-6. Summary of Effects and Mitigation Measures for the WSLIP, CHP Academy EIP, and The Rivers EIP

Effect	NEPA/CEQA Finding	Mitigation Measure	Finding with Mitigation Considered
FLOOD CONTROL AND GEOMORPHIC CONDITIONS			
Flood and Recreation Program Alternatives			
FC-1: Change in Water Surface Elevations and Flood Safety Attributable to Project Design (Flood Program, local and upstream)	Beneficial	N/A	N/A

EJ-1: Disproportionate Effect on Minority or Low-Income Populations	No effect	N/A	N/A
VISUAL RESOURCES			
Flood and Recreation Program Alternatives			
VIS-1: Affect a Scenic Vista	Significant	No feasible mitigation	Significant and unavoidable
VIS-2: Create a New Source of Light or Glare	Significant	No feasible mitigation	Significant and unavoidable

Effect	NEPA/CEQA Finding	Mitigation Measure	Finding with Mitigation Considered
VIS-3: Affect Scenic Resources along a Designated Scenic Highway	No effect	N/A	N/A
VIS-4: Cause Temporary Visual Effects as a Result of Construction Activities	Less than significant	N/A	N/A
VIS-5: Affect the Existing Visual Character or Quality of the Site and Its Surroundings as a Result of Construction, Operations, and Maintenance	Significant	No feasible mitigation	Significant and unavoidable
VIS-6: Conflict with Local Visual Resource Policies	Significant	No feasible mitigation	Significant and unavoidable
CHP Academy Applicant Preferred Alternative			
VIS-2: Create a New Source of Light or Glare	Significant	No feasible mitigation	Significant and unavoidable
VIS-4: Cause Temporary Visual Effects as a Result of Construction Activities	Less than significant	N/A	N/A
CHP Academy Alternative B			
VIS-2: Create a New Source of Light or Glare	Significant	No feasible mitigation	Significant and unavoidable
VIS-4: Cause Temporary Visual Effects as a Result of Construction Activities	Less than significant	N/A	N/A
The Rivers Applicant Preferred Alternative			
VIS-2: Create a New Source of Light or Glare	Significant	No feasible mitigation	Significant and unavoidable
VIS-4: Cause Temporary Visual Effects as a Result of Construction Activities	Less than significant	N/A	N/A
VIS-5: Affect the Existing Visual Character or Quality of the Site and Its Surroundings as a Result of Construction, Operations, and Maintenance	Significant	No feasible mitigation	Significant and unavoidable
VIS-6: Conflict with Local Visual Resource Policies	Significant	No feasible mitigation	Significant and unavoidable
The Rivers Alternative B			
VIS-2: Create a New Source of Light or Glare	Significant	No feasible mitigation	Significant and unavoidable

Effect	NEPA/CEQA Finding	Mitigation Measure	Finding with Mitigation Considered
VIS-4: Cause Temporary Visual Effects as a Result of Construction Activities	Less than significant	N/A	N/A
VIS-5: Affect the Existing Visual Character or Quality of the Site and Its Surroundings as a Result of Construction, Operations, and Maintenance	Significant	No feasible mitigation	Significant and unavoidable
VIS-6: Conflict with Local Visual Resource Policies	Significant	No feasible mitigation	Significant and unavoidable
RECREATION			
Flood and Recreation Program Alternatives			
REC-1: Temporary Disruption of Recreation Opportunities during Construction (Sacramento River North Levee, Sacramento River South Levee, Port North Levee, Port South Levee, DWSC West Levee, DWSC East Levee, Sacramento Bypass Levee)	Less than significant	N/A	N/A
REC-1: Temporary Disruption of Recreation Opportunities during Construction (Yolo Bypass Levee)	Significant	REC-MM-1: Temporarily Re-Route Yolo Causeway Bicycle Path	Less than significant
REC-2: Temporary Obstruction of Access to Marina or Boat Launch Facilities (Sacramento River North Levee, Sacramento River South Levee, Port South Levee)	Less than significant	N/A	N/A
REC-3: Long-Term Reduction in Quality of Existing Recreation Opportunities in the Levee Corridor (Sacramento River North Levee, Sacramento River South Levee, Port North Levee, Port South Levee, DWSC West Levee, DWSC East Levee, Yolo Bypass Levee)	Significant	No feasible mitigation	Significant and unavoidable
REC-3: Long-Term Reduction in Quality of Existing Recreation Opportunities in the Levee Corridor (Setback Levee on the Sacramento River South Levee, Sacramento Bypass Levee)	Less than significant	N/A	N/A
REC-4: Permanent Loss of Recreation Facilities or Opportunities (Sacramento River North Levee, Sacramento River South Levee, Setback Levee on the Sacramento River South Levee, Stability Berm on the Sacramento River South Levee, Port South Levee, Yolo Bypass Levee)	Less than significant	N/A	N/A
REC-4: Permanent Loss of Recreation Opportunities (Flood Wall on the Port South Levee)	Significant	REC-MM-2: Preserve Access to Barge Canal Recreation Access	Less than significant

Effect	NEPA/CEQA Finding	Mitigation Measure	Finding with Mitigation Considered
REC-5: Temporary Disruption of Recreational Boating Activities during Construction (Sacramento River North and Sacramento River South Levees, DWSC West and DWSC East Levees)	Less than significant	N/A	N/A
REC-6: Long-Term Increase in Recreation Opportunities (Sacramento River North Levee, Sacramento River South Levee, Port North Levee, Port South Levee, South Cross Levee, DWSC East Levee, Yolo Bypass Levee and Sacramento Bypass Levee)	Beneficial	N/A	N/A
CHP Academy Applicant Preferred Alternative			
REC-1: Temporary Disruption of Recreation Opportunities during Construction	Less than significant	N/A	N/A
REC-3: Long-Term Reduction in Quality of Existing Recreation Opportunities in the Levee Corridor	Less than significant	N/A	N/A
REC-6: Long-Term Increase in Recreation Opportunities	Beneficial	N/A	N/A
CHP Academy Alternative B			
REC-1: Temporary Disruption of Recreation Opportunities during Construction	Less than significant	N/A	N/A
REC-3: Long-Term Reduction in Quality of Existing Recreation Opportunities in the Levee Corridor	Less than significant	N/A	N/A
REC-6: Long-Term Increase in Recreation Opportunities	Beneficial	N/A	N/A
The Rivers Applicant Preferred Alternative			
REC-1: Temporary Disruption of Recreation Opportunities during Construction	Less than significant	N/A	N/A
REC-3: Long-Term Reduction in Quality of Existing Recreation Opportunities in the Levee Corridor	Significant	No feasible mitigation	Significant and unavoidable
REC-4: Permanent Loss of Recreation Facilities or Opportunities	Less than significant	N/A	N/A
REC-6: Long-Term Increase in Recreation Opportunities	Beneficial	N/A	N/A
The Rivers Alternative B			
REC-1: Temporary Disruption of Recreation Opportunities during Construction	Less than significant	N/A	N/A
REC-3: Long-Term Reduction in Quality of Existing Recreation Opportunities in the Levee Corridor	Significant	No feasible mitigation	Significant and unavoidable

Effect	NEPA/CEQA Finding	Mitigation Measure	Finding with Mitigation Considered
REC-4: Permanent Loss of Recreation Facilities or Opportunities	Less than significant	N/A	N/A
REC-6: Long-Term Increase in Recreation Opportunities	Beneficial	N/A	N/A
UTILITIES AND PUBLIC SERVICES			
Flood and Recreation Program Alternatives			
PUB-1: Damage of Public Utility Infrastructure and Disruption of Service	Significant	PUB-MM-1: Verify Utility Locations, Coordinate with Utility Providers, Prepare a Response Plan, and Conduct Worker Training	Less than significant
PUB-2: Exceed the Capacity or Shorten the Lifespan of Local Solid Waste Landfills as a Result of Construction	Less than significant	N/A	N/A
PUB-3: Expansion of Stormwater Drainage Facilities	Less than significant	N/A	N/A
CHP Academy Applicant Preferred Alternative			
PUB-1: Damage of Public Utility Infrastructure and Disruption of Service	Significant	PUB-MM-1: Verify Utility Locations, Coordinate with Utility Providers, Prepare a Response Plan, and Conduct Worker Training	Less than significant
PUB-2: Exceed the Capacity or Shorten the Lifespan of Local Solid Waste Landfills as a Result of Construction	Less than significant	N/A	N/A
CHP Academy Alternative B			
PUB-1: Damage of Public Utility Infrastructure and Disruption of Service	Significant	PUB-MM-1: Verify Utility Locations, Coordinate with Utility Providers, Prepare a Response Plan, and Conduct Worker Training	Less than significant
PUB-2: Exceed the Capacity or Shorten the Lifespan of Local Solid Waste Landfills as a Result of Construction	Less than significant	N/A	N/A
PUB-3: Expansion of Stormwater Drainage Facilities	Less than significant	N/A	N/A
The Rivers Applicant Preferred Alternative			
PUB-1: Damage of Public Utility Infrastructure and Disruption of Service	Significant	PUB-MM-1: Verify Utility Locations, Coordinate with Utility Providers, Prepare a Response Plan, and Conduct Worker Training	Significant and unavoidable
PUB-2: Exceed the Capacity or Shorten the Lifespan of Local Solid Waste Landfills as a Result of Construction	Less than significant	N/A	N/A

Effect	NEPA/CEQA Finding	Mitigation Measure	Finding with Mitigation Considered
The Rivers Alternative B			
PUB-1: Damage of Public Utility Infrastructure and Disruption of Service	Significant	PUB-MM-1: Verify Utility Locations, Coordinate with Utility Providers, Prepare a Response Plan, and Conduct Worker Training	Significant and unavoidable
PUB-2: Exceed the Capacity or Shorten the Lifespan of Local Solid Waste Landfills as a Result of Construction	Less than significant	N/A	N/A
PUBLIC HEALTH AND ENVIRONMENTAL HAZARDS			
Flood and Recreation Program Alternatives			
PH-1: Incidental Release of Hazardous Materials during Construction	Less than significant	N/A	N/A
PH-2: Exposure to Hazardous Materials Encountered at Project Sites	Significant	WQ-MM-1 Implement Measures to Maintain Surface Water Quality and Groundwater Quality WQ-MM-2: Implement Provisions for Dewatering PH-MM-1: Complete Phase I and Phase II (If Necessary) Environmental Site Assessment Investigations and Implement Required Measures	Less than significant
PH-3: Safety Hazards from the Construction Site and Vehicles	Less than significant	N/A	N/A
PH-4: Protection of People or Structures from Flood Hazards	Beneficial	N/A	N/A
PH-5: Hazardous Materials, Substances, or Waste Handled or Emitted within 0.25 Mile of an Existing or Proposed School	Significant	PH-MM-2: Notify Washington Unified School District and Applicable Schools Located within 0.25 Mile of Project Construction Activities	Less than significant
CHP Academy Applicant Preferred Alternative			
PH-1: Incidental Release of Hazardous Materials during Construction	Less than significant	N/A	N/A
PH-2: Exposure to Hazardous Materials Encountered at Project Site	Significant	WQ-MM-1 Implement Measures to Maintain Surface Water Quality and Groundwater Quality WQ-MM-2: Implement Provisions for Dewatering PH-MM-1: Complete Phase I and Phase II (If Necessary) Environmental Site Assessment Investigations and Implement Required Measures	Less than significant
PH-3: Safety Hazards from the Construction Site and Vehicles	Less than significant	N/A	N/A

Effect	NEPA/CEQA Finding	Mitigation Measure	Finding with Mitigation Considered

ES.1.1 Document Purpose and Structure ES-1
ES.1.2 WSLIP Regional Setting and Study Area ES-3
ES.1.3 Levee Problems and Flood Management Deficiencies ES-4
ES.1.4 WSLIP Purpose and Need ES-5
ES.1.5 WSLIP Background ES-6
ES.1.6 Related Actions, Programs, and Planning Efforts ES-9
ES.1.7 Community Outreach, Agency Coordination, and Issues of Known Controversy ES-10
Chapter ES.2 Alternatives ES-11
ES.2.1 Introduction ES-11
ES.2.2 General Information about Alternatives ES-11
ES.2.3 Program-Level Alternatives Considered but Not Carried Forward ES-12
ES.2.4 No Action Alternative ES-13
ES.2.5 Program-Level Alternatives for Levee and Flood Management Deficiencies ES-15
ES.2.6 Program-Level Alternatives for Recreation ES-16
ES.2.7 Summary of Program Improvements by Reach ES-16
ES.2.8 Project-Level Alternatives ES-17
ES.2.9 Environmental Commitments ES-18

Chapter 1 Introduction 1-1
1.1 Document Purpose and Structure 1-2
1.1.1 Document Overview 1-2
1.1.2 Document Organization 1-2
1.1.3 NEPA and CEQA Requirements 1-3
1.1.4 Application of NEPA and CEQA Principles and Terminology 1-5
1.1.5 Resource Analysis Structure 1-6
1.1.6 Elevation Datum Used in This Document 1-8
1.2 WSLIP Regional Setting and Study Area 1-9
1.2.1 WSLIP Study Reaches and Potential Construction Footprint 1-10
1.3 Levee Problems and Flood Management Deficiencies 1-11
1.3.1 Overview of Levee Failure Mechanisms and Deficiencies 1-11
1.3.2 Inadequate Levee Height 1-12
1.3.3 Through-Seepage 1-12
1.3.4 Under-Seepage 1-13
1.3.5 Slope Stability and Geometry 1-13
1.3.6 Erosion 1-13
1.3.7 Non-Compliant Vegetation and Levee Encroachments 1-13

1.4 WSLIP Purpose and Need 1-14
1.4.1 Purpose, Approach, and Objectives 1-14
1.4.2 Need for Action 1-14
1.5 WSLIP Background 1-17
1.5.1 Regional Flood Management History 1-18
1.5.2 Local Flood Management History, Programs, and Activities 1-19
1.5.3 Local Recreation Needs 1-21
1.6 Related Actions, Programs, and Planning Efforts 1-22
1.7 Community Outreach, Agency Coordination, and Issues of Known Controversy 1-27
1.7.1 Community Outreach 1-27
1.7.2 Agency Consultation and Coordination 1-28
1.7.3 Issues of Known or Expected Controversy 1-30

Chapter 2 Alternatives 2-1
2.1 Introduction 2-1
2.2 General Information about Alternatives 2-1
2.2.1 Approach to Alternatives 2-1
2.2.2 Alternative Screening Process 2-2
2.3 Program-Level Alternatives Considered but Not Carried Forward 2-4
2.3.1 Reoperation of Upstream Reservoirs 2-4
2.3.2 Reoperation of Weirs 2-4
2.3.3 Development of Additional Upstream Storage 2-4
2.3.4 Raising Building Pads 2-5
2.3.5 DWSC Closure Structure and Gated Weir 2-5
2.4 No Action Alternative 2-5
2.4.1 Introduction to No Action 2-5
2.4.2 No Flood Improvements Implemented under the No Action Alternative 2-6
2.4.3 Relationship of Flood Map Modernization to No Action 2-9
2.4.4 Levee Vegetation Policy and No Action 2-9
2.4.5 Recreation under No Action 2-10
2.5 Program-Level Alternatives for Levee and Flood Management Deficiencies 2-10
2.5.1 Flood Program Improvements for Levee Height 2-11
2.5.2 Flood Program Improvements for Seepage Control 2-16
2.5.3 Flood Program Improvements for Slope Stability and Geometry 2-26
2.5.4 Flood Program Improvements for Erosion Control 2-28
2.5.5 Other Flood Program Improvements 2-29
2.6 Program-Level Alternatives for Recreation 2-32
2.7 Summary of Program Improvements by Reach 2-40
2.8 Project-Level Alternatives 2-40
2.8.1 Introduction and Project Phasing 2-40
2.8.2 CHP Academy EIP 2-41
2.8.3 The Rivers EIP 2-42
2.9 Environmental Commitments 2-43

Chapter 3 Affected Environment and Environmental Consequences 3-1
3.1 Introduction 3-1
3.1.1 Resources 3-1
Section 3.2 Flood Control and Geomorphic Conditions 3.2-1
3.2.1 Introduction 3.2-1
3.2.2 Affected Environment 3.2-2
3.2.2.1 Regulatory Setting 3.2-2
3.2.2.2 Environmental Setting 3.2-9
3.2.3 Environmental Consequences 3.2-58
3.2.3.1 Methods 3.2-58
3.2.3.2 Determination of Effects 3.2-58
3.2.3.3 Effects and Mitigation Measures 3.2-60
Section 3.3 Water Quality and Groundwater Resources 3.3-1
3.3.1 Introduction 3.3-1
3.3.2 Affected Environment 3.3-1
3.3.2.1 Regulatory Setting 3.3-1
3.3.2.2 Environmental Setting 3.3-7
3.3.3 Environmental Consequences 3.3-12
3.3.3.1 Assessment Methods 3.3-12
3.3.3.2 Determination of Effects 3.3-12
3.3.3.3 Effects and Mitigation Measures 3.3-12
Section 3.4 Geology, Seismicity, Soils, and Mineral Resources 3.4-1
3.4.1 Introduction 3.4-1
3.4.2 Affected Environment 3.4-1
3.4.2.1 Regulatory Setting 3.4-1
3.4.2.2 Environmental Setting 3.4-8
3.4.3 Environmental Consequences 3.4-13
3.4.3.1 Assessment Methods 3.4-13
3.4.3.2 Determination of Effects 3.4-14
3.4.3.3 Effects and Mitigation Measures 3.4-15
Section 3.5 Transportation and Navigation 3.5-1
3.5.1 Introduction 3.5-1
3.5.1.1 Terminology 3.5-1
3.5.2 Affected Environment 3.5-2
3.5.2.1 Regulatory Setting 3.5-2
3.5.2.2 Environmental Setting 3.5-5
3.5.3 Environmental Consequences 3.5-12
3.5.3.1 Assessment Methods 3.5-12
3.5.3.2 Determination of Effects 3.5-13
3.5.3.3 Effects and Mitigation Measures 3.5-13
Section 3.6 Air Quality and Climate Change 3.6-1
3.6.1 Introduction 3.6-1
3.6.2 Affected Environment 3.6-1
3.6.2.1 Air Quality Regulatory Setting 3.6-1
3.6.2.2 Climate Change Regulatory Setting 3.6-7

3.6.2.3 Air Quality Environmental Setting 3.6-11
3.6.2.4 Climate Change Environmental Setting 3.6-17
3.6.3 Environmental Consequences 3.6-18
3.6.3.1 Air Quality Assessment Methods 3.6-19
3.6.3.2 Air Quality Determination of Effects 3.6-20
3.6.3.3 Air Quality Effects and Mitigation Measures 3.6-20
3.6.3.4 Climate Change Assessment Methods 3.6-28
3.6.3.5 Climate Change Determination of Effects 3.6-29
3.6.3.6 Climate Change Effects and Mitigation Measures 3.6-29

Section 3.7 Noise 3.7-1
3.7.1 Introduction 3.7-1
3.7.2 Affected Environment 3.7-1
3.7.2.1 Fundamentals of Noise and Vibration 3.7-1
3.7.2.2 Regulatory Setting 3.7-5
3.7.2.3 Environmental Setting 3.7-9
3.7.3 Environmental Consequences 3.7-10
3.7.3.1 Assessment Methods 3.7-11
3.7.3.2 Determination of Effects 3.7-11
3.7.3.3 Effects and Mitigation Measures 3.7-12

Section 3.8 Vegetation and Wetlands 3.8-1
3.8.1 Introduction 3.8-1
3.8.2 Affected Environment 3.8-2
3.8.2.1 Regulatory Setting 3.8-2
3.8.2.2 Environmental Setting 3.8-9
3.8.3 Environmental Consequences 3.8-21
3.8.3.1 Assessment Methods 3.8-21
3.8.3.2 Determination of Effects 3.8-21
3.8.3.3 Effects and Mitigation Measures 3.8-23

Section 3.9 Fisheries and Aquatics 3.9-1
3.9.1 Introduction 3.9-1
3.9.2 Affected Environment 3.9-1
3.9.2.1 Regulatory Setting 3.9-1
3.9.2.2 Environmental Setting 3.9-6
3.9.3 Environmental Consequences 3.9-23
3.9.3.1 Assessment Methods 3.9-23
3.9.3.2 Determination of Effects 3.9-24
3.9.3.3 Effects and Mitigation Measures 3.9-25

Section 3.10 Wildlife 3.10-1
3.10.1 Introduction 3.10-1
3.10.2 Affected Environment 3.10-2
3.10.2.1 Regulatory Setting 3.10-2
3.10.2.2 Environmental Setting 3.10-8
3.10.3 Environmental Consequences 3.10-29
3.10.3.1 Assessment Methods 3.10-29
3.10.3.2 Determination of Effects 3.10-30
3.10.3.3 Effects and Mitigation Measures 3.10-31

Section 3.11 Land Use and Agriculture 3.11-1
3.11.1 Introduction 3.11-1
3.11.2 Affected Environment 3.11-1
3.11.2.1 Regulatory Setting 3.11-1
3.11.2.2 Environmental Setting 3.11-5
3.11.3 Environmental Consequences 3.11-8
3.11.3.1 Assessment Methods 3.11-8
3.11.3.2 Determination of Effects 3.11-8
3.11.3.3 Effects and Mitigation Measures 3.11-9

Section 3.12 Socioeconomic and Community Effects 3.12-1
3.12.1 Introduction 3.12-1
3.12.2 Affected Environment 3.12-1
3.12.2.1 Regulatory Setting 3.12-1
3.12.2.2 Environmental Setting 3.12-3
3.12.3 Environmental Consequences 3.12-9
3.12.3.1 Assessment Methods 3.12-9
3.12.3.2 Determination of Effects 3.12-9
3.12.4 Effects and Mitigation Measures 3.12-10
3.12.4.1 No Action Alternative 3.12-10
3.12.4.2 Flood and Recreation Program Alternatives 3.12-11

Section 3.13 Environmental Justice 3.13-1
3.13.1 Introduction 3.13-1
3.13.2 Affected Environment 3.13-1
3.13.2.1 Regulatory Setting 3.13-1
3.13.2.2 Environmental Setting 3.13-1
3.13.3 Environmental Consequences 3.13-3
3.13.3.1 Assessment Methods 3.13-3
3.13.3.2 Determination of Effects 3.13-3
3.13.3.3 Effects and Mitigation Measures 3.13-4

Section 3.14 Visual Resources 3.14-1
3.14.1 Introduction 3.14-1
3.14.2 Affected Environment 3.14-1
3.14.2.1 Regulatory Setting 3.14-1
3.14.2.2 Environmental Setting 3.14-7
3.14.3 Environmental Consequences 3.14-19
3.14.3.1 Assessment Methods 3.14-19
3.14.3.2 Determination of Effects 3.14-20
3.14.3.3 Effects and Mitigation Measures 3.14-20

Section 3.15 Recreation 3.15-1
3.15.1 Introduction 3.15-1
3.15.2 Affected Environment 3.15-1
3.15.2.1 Regulatory Setting 3.15-1
3.15.2.2 Environmental Setting 3.15-8
3.15.3 Environmental Consequences 3.15-13
3.15.3.1 Assessment Methods 3.15-13
3.15.3.2 Determination of Effects 3.15-13

3.15.3.3 Effects and Mitigation Measures....3.15-14

Section 3.16 Utilities and Public Services 3.16-1
3.16.1 Introduction....3.16-1
3.16.2 Affected Environment....3.16-1
3.16.2.1 Regulatory Setting....3.16-1
3.16.2.2 Environmental Setting....3.16-4
3.16.3 Environmental Consequences....3.16-7
3.16.3.1 Assessment Methods....3.16-7
3.16.3.2 Determination of Effects....3.16-7
3.16.3.3 Effects and Mitigation Measures....3.16-8

Section 3.17 Public Health and Environmental Hazards 3.17-1
3.17.1 Introduction....3.17-1
3.17.2 Affected Environment....3.17-1
3.17.2.1 Regulatory Setting....3.17-1
3.17.2.2 Environmental Setting....3.17-6
3.17.3 Environmental Consequences....3.17-7
3.17.3.1 Assessment Methods....3.17-7
3.17.3.2 Determination of Effects....3.17-7
3.17.3.3 Effects and Mitigation Measures....3.17-8

Section 3.18 Cultural Resources.... 3.18-1
3.18.1 Introduction....3.18-1
3.18.2 Affected Environment....3.18-1
3.18.2.1 Regulatory Setting....3.18-1
3.18.2.2 Environmental Setting....3.18-7
3.18.3 Environmental Consequences....3.18-12
3.18.3.1 Assessment Methods....3.18-12
3.18.3.2 Determination of Effects....3.18-16
3.18.3.3 Effects and Mitigation Measures....3.18-17

Chapter 4 CHP Academy Early Implementation Project.... 4-1
4.1 Introduction....4-1
4.2 Purpose and Need....4-1
4.3 Alternatives....4-2
4.3.1 CHP Academy Project Alternatives....4-2
4.3.2 Environmental Commitments....4-18

Section 4.4 Flood Control and Geomorphic Conditions—CHP Academy Early Implementation Project 4-20
4.4.1 Affected Environment....4-20
4.4.1.1 Regulatory Setting....4-20
4.4.1.2 Environmental Setting....4-21
4.4.2 Environmental Consequences....4-27
4.4.2.1 Assessment Methods....4-27
4.4.2.2 Determination of Effects....4-27
4.4.3 Effects and Mitigation Measures....4-29
4.4.3.1 No Action Alternative....4-29
4.4.3.2 CHP Academy Applicant Preferred Alternative....4-29

4.4.3.3 CHP Academy Alternative B 4-31

Section 4.5 Water Quality and Groundwater Resources—CHP Academy Early Implementation Project 4-32

4.5.1 Affected Environment 4-32
4.5.1.1 Regulatory Setting 4-32
4.5.1.2 Environmental Setting 4-33
4.5.2 Environmental Consequences 4-33
4.5.2.1 Assessment Methods 4-33
4.5.2.2 Determination of Effects 4-33
4.5.3 Effects and Mitigation Measures 4-34
4.5.3.1 No Action Alternative 4-34
4.5.3.2 CHP Academy Applicant Preferred Alternative 4-34
4.5.3.3 CHP Academy Alternative B 4-38

Section 4.6 Geology, Seismicity, Soils, and Mineral Resources—CHP Academy Early Implementation Project 4-40

4.6.1 Affected Environment 4-40
4.6.1.1 Regulatory Setting 4-40
4.6.1.2 Environmental Setting 4-40
4.6.2 Environmental Consequences 4-42
4.6.2.1 Assessment Methods 4-42
4.6.2.2 Determination of Effects 4-42
4.6.3 Effects and Mitigation Measures 4-43
4.6.3.1 No Action Alternative 4-43
4.6.3.2 CHP Academy Applicant Preferred Alternative 4-44
4.6.3.3 CHP Academy Alternative B 4-46

Section 4.7 Transportation and Navigation—CHP Academy Early Implementation Project 4-47

4.7.1 Affected Environment 4-47
4.7.1.1 Terminology 4-47
4.7.1.2 Regulatory Setting 4-47
4.7.1.3 Environmental Setting 4-47
4.7.2 Environmental Consequences 4-50
4.7.2.1 Assessment Methods 4-50
4.7.2.2 Determination of Effects 4-51
4.7.3 Effects and Mitigation Measures 4-52
4.7.3.1 No Action Alternative 4-52
4.7.3.2 CHP Academy Applicant Preferred Alternative 4-52
4.7.3.3 CHP Academy Alternative B 4-54

Section 4.8 Air Quality and Climate Change—CHP Academy Early Implementation Project 4-57

4.8.1 Affected Environment 4-57
4.8.1.1 Air Quality Regulatory Setting 4-57
4.8.1.2 Climate Change Regulatory Setting 4-58
4.8.1.3 Air Quality Environmental Setting 4-58
4.8.1.4 Climate Change Environmental Setting 4-60
4.8.2 Air Quality Environmental Consequences 4-60
4.8.2.1 Air Quality Assessment Methods 4-60
4.8.2.2 Air Quality Determination of Effects 4-61

4.8.3 Air Quality Effects and Mitigation Measures 4-61
4.8.3.1 No Action Alternative 4-61
4.8.3.2 CHP Academy Applicant Preferred Alternative 4-62
4.8.3.3 CHP Academy Alternative B 4-69
4.8.4 Climate Change Environmental Consequences 4-73
4.8.4.1 Climate Change Assessment Methods 4-73
4.8.4.2 Climate Change Determination of Effects 4-74
4.8.5 Climate Change Effects and Mitigation Measures 4-74
4.8.5.1 No Action Alternative 4-74
4.8.5.2 CHP Academy Applicant Preferred Alternative 4-74
4.8.5.3 CHP Academy Alternative B 4-75

Section 4.9 Noise—CHP Academy Early Implementation Project 4-77
4.9.1 Affected Environment 4-77
4.9.1.1 Regulatory Setting 4-77
4.9.1.2 Environmental Setting 4-77
4.9.2 Environmental Consequences 4-78
4.9.2.1 Assessment Methods 4-78
4.9.2.2 Determination of Effects 4-79
4.9.3 Effects and Mitigation Measures 4-80
4.9.3.1 No Action Alternative 4-80
4.9.3.2 CHP Academy Applicant Preferred Alternative 4-80
4.9.3.3 CHP Academy Alternative B 4-82

Section 4.10 Vegetation and Wetlands—CHP Academy Early Implementation Project 4-84
4.10.1 Affected Environment 4-84
4.10.1.1 Regulatory Setting 4-84
4.10.1.2 Environmental Setting 4-85
4.10.2 Environmental Consequences 4-95
4.10.2.1 Assessment Methods 4-96
4.10.2.2 Determination of Effects 4-96
4.10.3 Effects and Mitigation Measures 4-97
4.10.3.1 No Action Alternative 4-97
4.10.3.2 CHP Academy Applicant Preferred Alternative 4-98
4.10.3.3 CHP Academy Alternative B 4-103

Section 4.11 Fisheries and Aquatic Resources—CHP Academy Early Implementation Project 4-105
4.11.1 Affected Environment 4-105
4.11.1.1 Regulatory Setting 4-105
4.11.1.2 Environmental Setting 4-105
4.11.2 Environmental Consequences 4-106
4.11.2.1 Assessment Methods 4-106
4.11.2.2 Determinations of Effects 4-107
4.11.3 Effects and Mitigation Measures 4-108
4.11.3.1 No Action Alternative 4-108
4.11.3.2 CHP Academy Applicant Preferred Alternative 4-108
4.11.3.3 CHP Academy Alternative B 4-109

Section 4.12 Wildlife—CHP Academy Early Implementation Project 4-110
4.12.1 Affected Environment 4-110

4.12.1.1 Regulatory Setting 4-110
4.12.1.2 Environmental Setting 4-110
4.12.2 Environmental Consequences 4-125
4.12.2.1 Assessment Methods 4-125
4.12.2.2 Determination of Effects 4-126
4.12.3 Effects and Mitigation Measures 4-127
4.12.3.1 No Action Alternative 4-127
4.12.3.2 CHP Academy Applicant Preferred Alternative 4-127
4.12.3.3 CHP Academy Alternative B 4-137

Section 4.13 Land Use and Agriculture—CHP Academy Early Implementation Project 4-138
4.13.1 Affected Environment 4-138
4.13.1.1 Regulatory Environment 4-138
4.13.1.2 Environmental Setting 4-138
4.13.2 Environmental Consequences 4-139
4.13.2.1 Assessment Methods 4-139
4.13.2.2 Determination of Effects 4-139
4.13.3 Effects and Mitigation Measures 4-140
4.13.3.1 No Action Alternative 4-140
4.13.3.2 CHP Academy Applicant Preferred Alternative 4-140
4.13.3.3 CHP Academy Alternative B 4-141

Section 4.14 Socioeconomic and Community Effects—CHP Academy Early Implementation Project 4-142
4.14.1 Affected Environment 4-142
4.14.1.1 Regulatory Environment 4-142
4.14.1.2 Environmental Setting 4-142
4.14.2 Environmental Consequences 4-143
4.14.2.1 Assessment Methods 4-143
4.14.2.2 Determinations of Effects 4-143
4.14.3 Effects and Mitigation Measures 4-143
4.14.3.1 No Action Alternative 4-143
4.14.3.2 CHP Academy Applicant Preferred Alternative 4-144
4.14.3.3 CHP Academy Alternative B 4-144

Section 4.15 Environmental Justice—CHP Academy Early Implementation Project 4-146
4.15.1 Affected Environment 4-146
4.15.1.1 Regulatory Environment 4-146
4.15.1.2 Environmental Setting 4-146
4.15.2 Environmental Consequences 4-147
4.15.2.1 Assessment Methods 4-148
4.15.2.2 Determination of Effects 4-148
4.15.3 Effects and Mitigation Measures 4-148
4.15.3.1 No Action Alternative 4-148
4.15.3.2 CHP Academy Applicant Preferred Alternative 4-148
4.15.3.3 CHP Academy Alternative B 4-149

Section 4.16 Visual Resources—CHP Academy Early Implementation Project 4-150
4.16.1 Affected Environment 4-150
4.16.1.1 Regulatory Setting 4-150

4.16.1.2 Environmental Setting 4-150
4.16.2 Environmental Consequences 4-152
4.16.2.1 Assessment Methods 4-152
4.16.2.2 Determination of Effects 4-153
4.16.3 Effects and Mitigation Measures 4-153
4.16.3.1 No Action Alternative 4-153
4.16.3.2 CHP Academy Applicant Preferred Alternative 4-154
4.16.3.3 CHP Academy Alternative B 4-155

Section 4.17 Recreation—CHP Academy Early Implementation Project 4-156
4.17.1 Affected Environment 4-156
4.17.1.1 Regulatory Setting 4-156
4.17.1.2 Environmental Setting 4-156
4.17.2 Environmental Consequences 4-156
4.17.2.1 Assessment Methods 4-157
4.17.2.2 Determination of Effects 4-157
4.17.3 Effects and Mitigation Measures 4-157
4.17.3.1 No Action Alternative 4-157
4.17.3.2 CHP Academy Applicant Preferred Alternative 4-158
4.17.3.3 CHP Academy Alternative B 4-159

Section 4.18 Utilities and Public Services—CHP Academy Early Implementation Project 4-161
4.18.1 Affected Environment 4-161
4.18.1.1 Regulatory Setting 4-161
4.18.1.2 Environmental Setting 4-161
4.18.2 Environmental Consequences 4-162
4.18.2.1 Assessment Methods 4-163
4.18.2.2 Determination of Effects 4-163
4.18.3 Effects and Mitigation Measures 4-163
4.18.3.1 No Action Alternative 4-163
4.18.3.2 CHP Academy Applicant Preferred Alternative 4-164
4.18.3.3 CHP Academy Alternative B 4-166

Section 4.19 Public Health and Environmental Hazards—CHP Academy Early Implementation Project 4-168
4.19.1 Affected Environment 4-168
4.19.1.1 Regulatory Setting 4-168
4.19.1.2 Environmental Setting 4-168
4.19.2 Environmental Consequences 4-169
4.19.2.1 Assessment Methods 4-169
4.19.2.2 Determination of Effects 4-170
4.19.3 Effects and Mitigation Measures 4-170
4.19.3.1 No Action Alternative 4-170
4.19.3.2 CHP Academy Applicant Preferred Alternative 4-171
4.19.3.3 CHP Academy Alternative B 4-174

Section 4.20 Cultural Resources—CHP Academy Early Implementation Project 4-176
4.20.1 Affected Environment 4-176
4.20.1.1 Regulatory Setting 4-176
4.20.1.2 Environmental Setting 4-176

4.20.2 Environmental Consequences 4-179
4.20.2.1 Assessment Methods 4-180
4.20.2.2 Determination of Effects 4-180
4.20.3 Effects and Mitigation Measures 4-181
4.20.3.1 No Action Alternative 4-181
4.20.3.2 CHP Academy Applicant Preferred Alternative 4-181
4.20.3.3 CHP Academy Alternative B 4-183

Chapter 5 The Rivers Early Implementation Project 5-1
5.1 Introduction 5-1
5.2 Purpose and Need 5-1
5.3 Alternatives 5-2
5.3.1 The Rivers Project Alternatives 5-2
5.3.2 Environmental Commitments 5-17

Section 5.4 Flood Control and Geomorphic Conditions—The Rivers Early Implementation Project 5-18
5.4.1 Affected Environment 5-18
5.4.1.1 Regulatory Setting 5-18
5.4.1.2 Environmental Setting 5-19
5.4.2 Environmental Consequences 5-27
5.4.2.1 Assessment Methods 5-27
5.4.2.2 Determination of Effects 5-27
5.4.3 Effects and Mitigation Measures 5-28
5.4.3.1 No Action Alternative 5-28
5.4.3.2 The Rivers Applicant Preferred Alternative 5-29
5.4.3.3 The Rivers Alternative B 5-30

Section 5.5 Water Quality and Groundwater Resources—The Rivers Early Implementation Project 5-32
5.5.1 Affected Environment 5-32
5.5.1.1 Regulatory Setting 5-32
5.5.1.2 Environmental Setting 5-33
5.5.2 Environmental Consequences 5-33
5.5.2.1 Assessment Methods 5-33
5.5.2.2 Determination of Effects 5-33
5.5.3 Effects and Mitigation Measures 5-34
5.5.3.1 No Action Alternative 5-34
5.5.3.2 The Rivers Applicant Preferred Alternative 5-34
5.5.3.3 The Rivers Alternative B 5-39

Section 5.6 Geology, Seismicity, Soils, and Mineral Resources—The Rivers Early Implementation Project 5-41
5.6.1 Affected Environment 5-41
5.6.1.1 Regulatory Setting 5-41
5.6.1.2 Environmental Setting 5-41
5.6.2 Environmental Consequences 5-43
5.6.2.1 Assessment Methods 5-43
5.6.2.2 Determination of Effects 5-43
5.6.3 Effects and Mitigation Measures 5-44

5.6.3.1 No Action Alternative 5-44
5.6.3.2 The Rivers Applicant Preferred Alternative 5-45
5.6.3.3 The Rivers Alternative B 5-46

Section 5.7 Transportation and Navigation—The Rivers Early Implementation Project 5-48
5.7.1 Affected Environment 5-48
5.7.1.1 Terminology 5-48
5.7.1.2 Regulatory Setting 5-48
5.7.1.3 Environmental Setting 5-48
5.7.2 Environmental Consequences 5-51
5.7.2.1 Assessment Methods 5-52
5.7.2.2 Determination of Effects 5-53
5.7.3 Effects and Mitigation Measures 5-53
5.7.3.1 No Action Alternative 5-53
5.7.3.2 The Rivers Applicant Preferred Alternative 5-54
5.7.3.3 The Rivers Alternative B 5-57

Section 5.8 Air Quality and Climate Change—The Rivers Early Implementation Project 5-60
5.8.1 Affected Environment 5-60
5.8.1.1 Air Quality Regulatory Setting 5-60
5.8.1.2 Climate Change Regulatory Setting 5-61
5.8.1.3 Air Quality Environmental Setting 5-61
5.8.1.4 Climate Change Environmental Setting 5-63
5.8.2 Air Quality Environmental Consequences 5-63
5.8.2.1 Air Quality Assessment Methods 5-63
5.8.2.2 Air Quality Determination of Effects 5-64
5.8.3 Air Quality Effects and Mitigation Measures 5-65
5.8.3.1 No Action Alternative 5-65
5.8.3.2 The Rivers Applicant Preferred Alternative 5-65
5.8.3.3 The Rivers Alternative B 5-72
5.8.4 Climate Change Environmental Consequences 5-76
5.8.4.1 Climate Change Assessment Methods 5-76
5.8.4.2 Climate Change Determination of Effects 5-77
5.8.5 Climate Change Effects and Mitigation Measures 5-77
5.8.5.1 No Action Alternative 5-77
5.8.5.2 The Rivers Applicant Preferred Alternative 5-77
5.8.5.3 The Rivers Alternative B 5-78

Section 5.9 Noise—The Rivers Early Implementation Project 5-80
5.9.1 Affected Environment 5-80
5.9.1.1 Regulatory Setting 5-80
5.9.1.2 Environmental Setting 5-80
5.9.2 Environmental Consequences 5-82
5.9.2.1 Assessment Methods 5-82
5.9.2.2 Determination of Effects 5-82
5.9.3 Effects and Mitigation Measures 5-83
5.9.3.1 No Action Alternative 5-83
5.9.3.2 The Rivers Applicant Preferred Alternative 5-83
5.9.3.3 The Rivers Alternative B 5-86

Section 5.10 Vegetation and Wetlands—The Rivers Early Implementation Project 5-91
5.10.1 Affected Environment 5-91
5.10.1.1 Regulatory Setting 5-91
5.10.1.2 Environmental Setting 5-92
5.10.2 Environmental Consequences 5-97
5.10.2.1 Assessment Methods 5-97
5.10.2.2 Determination of Effects 5-97
5.10.3 Effects and Mitigation Measures 5-99
5.10.3.1 No Action Alternative 5-99
5.10.3.2 The Rivers Applicant Preferred Alternative 5-100
5.10.3.3 The Rivers Alternative B 5-105

Section 5.11 Fisheries and Aquatic Resources—The Rivers Early Implementation Project 5-107
5.11.1 Affected Environment 5-107
5.11.1.1 Regulatory Setting 5-107
5.11.1.2 Environmental Setting 5-107
5.11.2 Environmental Consequences 5-108
5.11.2.1 Assessment Methods 5-108
5.11.2.2 Determinations of Effects 5-108
5.11.3 Effects and Mitigation Measures 5-109
5.11.3.1 No Action Alternative 5-109
5.11.3.2 The Rivers Applicant Preferred Alternative 5-110
5.11.3.3 The Rivers Alternative B 5-112

Section 5.12 Wildlife—The Rivers Early Implementation Project 5-113
5.12.1 Affected Environment 5-113
5.12.1.1 Regulatory Setting 5-113
5.12.1.2 Environmental Setting 5-113
5.12.2 Environmental Consequences 5-127
5.12.2.1 Assessment Methods 5-127
5.12.2.2 Determination of Effects 5-128
5.12.3 Effects and Mitigation Measures 5-129
5.12.3.1 No Action Alternative 5-129
5.12.3.2 The Rivers Applicant Preferred Alternative 5-129
5.12.3.3 The Rivers Alternative B 5-138

Section 5.13 Land Use and Agriculture—The Rivers Early Implementation Project 5-139
5.13.1 Affected Environment 5-139
5.13.1.1 Regulatory Setting 5-139
5.13.1.2 Environmental Setting 5-139
5.13.2 Environmental Consequences 5-140
5.13.2.1 Assessment Methods 5-140
5.13.2.2 Determination of Effects 5-140
5.13.3 Effects and Mitigation Measures 5-141
5.13.3.1 No Action Alternative 5-141
5.13.3.2 The Rivers Applicant Preferred Alternative 5-141
5.13.3.3 The Rivers Alternative B 5-142

Section 5.14 Socioeconomic and Community Effects—The Rivers Early Implementation Project 5-144
5.14.1 Affected Environment 5-144
5.14.1.1 Regulatory Setting 5-144
5.14.1.2 Environmental Setting 5-144
5.14.2 Environmental Consequences 5-145
5.14.2.1 Assessment Methods 5-145
5.14.2.2 Determination of Effects 5-145
5.14.3 Effects and Mitigation Measures 5-146
5.14.3.1 No Action Alternative 5-146
5.14.3.2 The Rivers Applicant Preferred Alternative—Slurry Wall and Landside Slope Flattening 5-146
5.14.3.3 The Rivers Alternative B 5-147
Section 5.15 Environmental Justice—The Rivers Early Implementation Project 5-149
5.15.1 Affected Environment 5-149
5.15.1.1 Regulatory Setting 5-149
5.15.1.2 Environmental Setting 5-149
5.15.2 Environmental Consequences 5-150
5.15.2.1 Assessment Methods 5-151
5.15.2.2 Determination of Effects 5-151
5.15.3 Effects and Mitigation Measures 5-151
5.15.3.1 No Action Alternative 5-151
5.15.3.2 The Rivers Applicant Preferred Alternative 5-151
5.15.3.3 The Rivers Alternative B 5-152
Section 5.16 Visual Resources—The Rivers Early Implementation Project 5-153
5.16.1 Affected Environment 5-153
5.16.1.1 Regulatory Setting 5-153
5.16.1.2 Environmental Setting 5-153
5.16.2 Environmental Consequences 5-155
5.16.2.1 Assessment Methods 5-156
5.16.2.2 Determination of Effects 5-156
5.16.3 Effects and Mitigation Measures 5-156
5.16.3.1 No Action Alternative 5-156
5.16.3.2 The Rivers Applicant Preferred Alternative 5-157
5.16.3.3 The Rivers Alternative B 5-159
Section 5.17 Recreation—The Rivers Early Implementation Project 5-161
5.17.1 Affected Environment 5-161
5.17.1.1 Regulatory Setting 5-161
5.17.1.2 Environmental Setting 5-161
5.17.2 Environmental Consequences 5-161
5.17.2.1 Assessment Methods 5-162
5.17.2.2 Determination of Effects 5-162
5.17.3 Effects and Mitigation Measures 5-162
5.17.3.1 No Action Alternative 5-162
5.17.3.2 The Rivers Applicant Preferred Alternative 5-163
5.17.3.3 The Rivers Alternative B 5-165

Section 5.18 Utilities and Public Services—The Rivers Early Implementation Project 5-167
5.18.1 Affected Environment 5-167
5.18.1.1 Regulatory Setting 5-167
5.18.1.2 Environmental Setting 5-167
5.18.2 Environmental Consequences 5-169
5.18.2.1 Assessment Methods 5-169
5.18.2.2 Determination of Effects 5-169
5.18.3 Effects and Mitigation Measures 5-170
5.18.3.1 No Action Alternative 5-170
5.18.3.2 The Rivers Applicant Preferred Alternative 5-170
5.18.3.3 The Rivers Alternative B 5-172

Section 5.19 Public Health and Environmental Hazards—The Rivers Early Implementation Project 5-174
5.19.1 Affected Environment 5-174
5.19.1.1 Regulatory Setting 5-174
5.19.1.2 Environmental Setting 5-174
5.19.2 Environmental Consequences 5-175
5.19.2.1 Assessment Methods 5-176
5.19.2.2 Determination of Effects 5-176
5.19.3 Effects and Mitigation Measures 5-176
5.19.3.1 No Action Alternative 5-176
5.19.3.2 The Rivers Applicant Preferred Alternative 5-177
5.19.3.3 The Rivers Alternative B 5-180

Section 5.20 Cultural Resources—The Rivers Early Implementation Project 5-183
5.20.1 Affected Environment 5-183
5.20.1.1 Regulatory Setting 5-183
5.20.1.2 Environmental Setting 5-183
5.20.2 Environmental Consequences 5-186
5.20.2.1 Assessment Methods 5-186
5.20.2.2 Determination of Effects 5-186
5.20.3 Effects and Mitigation Measures 5-187
5.20.3.1 No Action Alternative 5-187
5.20.3.2 The Rivers Applicant Preferred Alternative 5-188

Chapter 6 Growth-Inducing and Cumulative Effects 6-1
6.1 Growth-Inducing Effects 6-1
6.1.1 Introduction 6-1
6.1.2 Affected Environment 6-1
6.1.3 Environmental Consequences 6-7
6.2 Cumulative Effects 6-9
6.2.1 Introduction 6-9
6.2.2 Approach to Cumulative Effect Analysis 6-9
6.2.3 Projects Considered for the Cumulative Assessment 6-10
6.2.4 Cumulative Effects by Resource 6-17

Chapter 7 Compliance with Applicable Laws, Policies, Plans, and Regulatory Framework 7-1
7.1 Introduction 7-1
7.2 Regulatory Framework 7-1

7.2.1 Federal Requirements 7-1
7.2.2 State Requirements 7-10
7.2.3 State and Regional Plan Consistency 7-21
7.2.4 Local Plan Consistency and Regulatory Requirements 7-21

Chapter 8 References 8-1

Chapter 9 List of Preparers 9-1
9.1 U.S. Army Corps of Engineers 9-1
9.2 West Sacramento Area Flood Control Agency 9-1
9.3 ICF International 9-2
9.4 Other Contributors 9-3

Chapter 10 List of Recipients. 9-1

Index

Appendix A Scoping Report

Appendix B U.S. Army Corps of Engineers Interim Vegetation Guidance for Control of Vegetation on Levees

Appendix C Supporting Documents, Figures, and Tables for Geomorphology and Flood Control

Appendix D Utility Assessment for Basin-Wide Problem Identification Report, HDR, Inc.

Appendix E Air Quality Information

Appendix F Plant Lists

Appendix G Correspondence Regarding Special-Status Species

Appendix H Public Health and Hazards: EDR Data Map Environmental Atlas

Appendix I Correspondence Regarding Cultural Resources

ES-1 Key to Effect Findings (by increasing adversity) ES-3
ES-2 Summary of Levee Deficiencies by Reach ES-5
ES-3 Summary of Levee Improvements and Deficiencies ES-16
ES-4 Summary of Program Improvements by Reach ES-17
ES-5 CHP Academy and The Rivers EIP Alternatives ES-18
ES-6 Summary of Effects and Mitigation Measures for the WSLIP, CHP Academy EIP, and The Rivers EIP ES-21

1-1. Key to General NEPA and CEQA Terminology 1-6
1-2. Key to Effect Findings (by increasing adversity) 1-7
1-3. Summary of Levee Deficiencies by Reach 1-12
1-4. Key Infrastructure and Facilities in West Sacramento 1-16
1-5. Responsible and Trustee Agencies 1-29
2-1. Summary of Levee Improvements and Deficiencies 2-11
2-2. Flood Wall Phases, Equipment, and Materials 2-12
2-3. Levee Raise (In-place, Adjacent, or Full)—Phases, Equipment, and Materials 2-13
2-4. Closure Structure Phases, Equipment, and Materials 2-16
2-5. Interior Drain Phases, Equipment, and Materials 2-17
2-6. Jet Grouting Phases, Equipment, and Materials 2-19
2-7. Relief Wells—Phases, Equipment, and Materials 2-20
2-8. Hybrid Berm—Phases, Equipment, and Materials 2-21
2-9. Semi-Pervious Berm—Phases, Equipment, and Materials 2-22
2-10. Sheet Pile Wall—Phases, Equipment, and Materials 2-23
2-11. Conventional Slot Trench Slurry Wall—Phases, Equipment, and Materials 2-25
2-12. Deep Soil Mixing Slurry Wall—Phases, Equipment, and Materials 2-26
2-13. Slope Flattening—Phases, Equipment, and Materials 2-27
2-14. Stability Berm—Phases, Equipment, and Materials 2-28
2-15. Rock Slope Protection—Phases, Equipment, and Materials 2-29
2-16. Setback Levee—Phases, Equipment, and Materials 2-30
2-17. Summary of Program Improvements by Reach 2-40
2-18. CHP Academy and The Rivers EIP Alternatives 2-41

2-19. CHP Academy EIP Flood Improvement Alternatives 2-42
2-20. The Rivers EIP Flood Improvement Alternatives 2-42
3.2-1. Monthly Mean Daily Flow Statistics for Sacramento River at Verona and Sacramento River at Freeport for 1990 through 2008 ..... 3.2-12
3.2-2. Projected Peak Flows for Sacramento River Sites 3.2-13
3.2-3. Hydraulic Geometry at the Erosion Sites 3.2-17
3.2-4. Historic Construction to Bring Levees to Project Standards 3.2-20
3.2-5. Thalweg Depths in 1997 at Three Bend Locations 3.2-22
3.2-6. Thalweg depths and 1997 Elevations at the Erosion Sites 3.2-22
3.2-7. Cross Section Changes at the Toe of the Eroding Banks 3.2-23
3.2-8. Historic Bank Line Shifts from 1986 to 2002 and 1964 to 1986 ..... 3.2-24
3.2-9. Historic Construction to Bring Levees Built by Local Interests to Project Standards 3.2-26
3.2-10. Seepage Summary 3.2-30
3.2-11. Reach Summary 3.2-31
3.2-12. Slope Stability Summary 3.2-33
3.2-13. Computed Maximum Water Surface Elevations 3.2-36
3.2-14. Sacramento River UNET Model Boundaries 3.2-42
3.2-15. Definition of Model Assumptions for Various Conditions 3.2-43
3.2-16. 1-in-100-Year Maximum Water Surface Elevation Summary, No Levee Failures 3.2-44
3.2-17. 1-in-200-Year Maximum Water Surface Elevation Summary, No Levee Failures 3.2-45
3.2-18. 1-in-500-Year Maximum Water Surface Elevation Summary, No Levee Failures 3.2-46
3.2-19. Extent of Levee Overtopping, 1-in-500-Year Flood Event, No Failures (all values approximate) 3.2-47
3.2-20a. 1-in-100 AEP Peak Flow (cfs) at Key Locations 3.2-49
3.2-20b. 1-in-200 AEP Peak Flow (cfs) at Key Locations 3.2-50
3.2-21a. 1-in-100 AEP Peak Water Surface Elevation (ft-NAVD 88) at Key Locations 3.2-50
3.2-21b. 1-in-200 AEP Peak Water Surface Elevation (ft-NGVD) at Key Locations 3.2-51
3.2-22. Calculated Sea-Level Rise for 25, 50, and 100 Years after Project Construction using Intermediate and High Rates of Sea-Level Rise 3.2-52
3.2-23. Impacts of Sea Level Rise on the Maximum Water Surface Elevations (WSE) at Locations on the Sacramento River 3.2-53
3.2-24. Peak Stages and Impacts 3.2-57
3.3-1. Monthly Average Total Suspended Solids and Turbidity on the Sacramento River at Freeport from 1997 to 2007 ..... 3.3-9
3.3-2. Monthly Average Physical Data for the Sacramento River at Freeport from 2003 to 2009 ..... 3.3-10

3.4-1. Soils in the Study Area 3.4-10
3.5-1. Level of Service Definitions for Urban Streets 3.5-2
3.5-2. LOS Criteria for Roadway Segments 3.5-4
3.5-3. AADT for Highways in the Program Area 3.5-7
3.5-4. ADT Counts along Hauling Routes 3.5-7
3.5-5. Existing Roadway LOS 3.5-8
3.5-6. Existing Intersection LOS 3.5-10
3.6-1. National and California Ambient Air Quality Standards 3.6-2
3.6-2. YSAQMD Significance Thresholds for Construction and Operational Emissions 3.6-6
3.6-3. SMAQMD Significance Thresholds for Construction and Operational Emissions 3.6-7
3.6-4. Ambient Air Quality Monitoring Data from the West Sacramento and Sacramento Stations (2006–2008) 3.6-15
3.6-5. Yolo County and Sacramento County Air Quality Attainment Status 3.6-16
3.6-6. Currently-Proposed GHG Significance Thresholds 3.6-30
3.7-1. Typical A-weighted Sound Levels 3.7-2
3.7-2. Vibration Source Levels for Construction Equipment 3.7-4
3.7-3. Human Response to Steady State Vibration 3.7-4
3.7-4. Human Response to Transient Vibration 3.7-5
3.7-5. Maximum Vibration Levels for Preventing Damage to Structures 3.7-5
3.7-6. City of West Sacramento Non-Transportation Noise Level Standards 3.7-6
3.7-7. City of West Sacramento Maximum Allowable Noise Exposure—Transportation Noise Sources 3.7-8
3.7-8. City of Sacramento Exterior Noise Level Standards 3.7-9
3.7-9. Population Density and Associated Ambient Noise Levels 3.7-10
3.7-10. Typical Construction Equipment Noise Emission Levels 3.7-13
3.7-11. Projected Construction Noise Levels due to a Grader, Compactor, and Dozer in the Program Vicinity 3.7-14
3.7-12. Slope Flattening: Projected Construction Noise Levels due to a Grader, Roller, and Large Truck in the Program Vicinity 3.7-15
3.7-13. Rock Slope Protection: Projected Construction Noise Levels due to an Excavator and a Loader 3.7-16
3.7-14. Sheet Pile Installation: Projected Construction Noise Levels due to a Crane, Haul Truck, and Impact Pile Driver in the Program Vicinity 3.7-17
3.7-15. Slurry Trench: Projected Construction Noise Levels due to a Compactor, Dozer, and Excavator in the Program Vicinity 3.7-18
3.7-16. Deep Soil Mixing: Projected Construction Noise Levels due to Four Augers, a Scraper, and a Batch Plant in the Program Vicinity 3.7-19

3.7-17. Relief Wells: Projected Construction Noise Levels due to an Excavator, Drill Rig, and a Water Truck in the Program Vicinity 3.7-20
3.7-18. Closure Structure: Projected Construction Noise Levels due to a Scraper, Excavator and Compactor in the Program Vicinity 3.7-21
3.7-19. Jet Grouting: Projected Construction Noise Levels due to Jet Grouting in the Program Vicinity 3.7-22
3.8-1. Summary of Yolo County General Plan Policies Related to Vegetation and Wetlands in the Program Area 3.8-5
3.8-2. Summary of City of West Sacramento General Plan Policies Related to Vegetation and Wetland Resources in the Program Area 3.8-6
3.8-3. Special-Status Plants Identified as Occurring in the Vicinity of the Study Area 3.8-16
3.9-1. Special-Status Fish Species with Potential to Occur in the Study Area 3.9-11
3.9-2. Life Stage Timing and Distribution of Selected Species Potentially Affected by the Proposed Program 3.9-17
3.10-1. Wildlife Species Observed in the Study Area 3.10-9
3.10-2. Special-Status Wildlife Species with Potential to Occur in the Study Area 3.10-14
3.12-1. Crop Yields and Values for Top-Producing Crops (and Corn and Grain) in Yolo County, 2008 ..... 3.12-4
3.12-2. West Sacramento's Largest Private Employers 3.12-5
3.12-3. Annual Yields and Values for Crops Grown in West Sacramento 3.12-6
3.12-4. Solano County's Largest Employers 3.12-8
3.12-5. Annual Yields and Values for Crops Grown in Solano County, 2008 ..... 3.12-8
3.13-1. Race/Origin Characteristics by City/County/State, 2000 and 2005 ..... 3.13-2
3.13-2. Household Poverty Status by City/County/State, 2000 ..... 3.13-3
3.18-1. Cultural Resources Located in the Program Study Area by Reach 3.18-15
4-1. Evaluation of CHP Academy EIP Alternatives 4-4
4-2. CHP Academy EIP Flood Improvement Alternatives 4-5
4-3. CHP Academy APA: Construction Schedule Options 4-13
4-4. CHP Academy Alternative B: Construction Schedule Options 4-17
4-5. CHP Academy EIP Recreation Improvements 4-18
4.4-1. Historic Construction to Bring Levees Built by Local Interests to Project Standards 4-22
4.4-2. Seepage Summary 4-24
4.4-3. Reach Summary 4-24
4.4-4. Slope Stability Summary 4-25
4.7-1. AADT for Highways in the CHP Academy Project Area 4-48
4.7-2. ADT, Peak-Hour Traffic, and LOS for Major Roadways in the CHP Academy Project Area 4-49

4.7-3. Estimated Daily Construction Traffic by Alternative and Construction Phase 4-51
4.7-4. Existing and Projected ADT on Haul Routes for the CHP Academy APA 4-53
4.8-1. Yolo County and Sacramento County Air Quality Attainment Status 4-59
4.8-2. Construction Phases, Schedule, and Activities: CHP Academy APA 4-62
4.8-3. Estimated Construction Emissions: CHP Academy APA 4-64
4.8-4. Construction Phases, Activities, Schedule, and Equipment: CHP Academy Alternative B 4-70
4.8-5. Estimated Construction Emissions: CHP Academy Alternative B 4-71
4.9-1. Modeled Peak Hour Traffic Noise Levels in the Vicinity of the CHP Academy Site 4-78
4.9-2. Typical Construction Equipment Noise Emission Levels 4-79
4.9-3. Projected Construction Noise Levels due to Slurry Cutoff Wall Installation (Including Staging/Mixing Area) 4-81
4.9-4. Projected Construction Noise Levels during Alternative B Stability Berm Construction 4-83
4.10-1. Special-Status Plants Identified as Occurring in the Project Region for the CHP Academy EIP 4-91
4.10-2. Arborist Survey Results for CHP Academy EIP 4-95
4.12-1. List of Wildlife Species Observed in the CHP Academy Study Area 4-111
4.12-2. Special-Status Wildlife Species with Potential to Occur in the CHP Academy Study Area 4-115
4.12-3. Elderberry Shrub Survey Results 4-129
4.15-1. Race/Origin Characteristics by City/County/State, 2000 and 2005 4-147
4.15-2. Household Poverty Status by City/County/State, 2000 4-147
4-18-1. Utilities Located in the CHP Academy Project Area 4-162
5-1. Evaluation of The Rivers EIP Alternatives 5-3
5-2. The Rivers EIP Flood Improvement Alternatives 5-4
5-3. The Rivers APA: Construction Schedule Options 5-11
5-4. The Rivers Alternative B: Construction Options 5-14
5-5. The Rivers EIP Recreation Improvements 5-16
5.4-1. Monthly Mean Daily Flow Statistics for Sacramento River at Verona and Sacramento River at Freeport for 1990 through 2008 5-19
5.4-2. Projected Peak Flows for Sacramento River Sites 5-20
5.4-3. Seepage Summary 5-23
5.4-4. Reach Summary 5-23
5.4-5. Slope Stability Summary 5-24
5.7-1. AADT for Highways in The Rivers Project Area 5-49

5.7-2. ADT, Peak-Hour Traffic, and LOS for Roadways in The Rivers Project Area 5-50
5.7-3. Estimated Daily Construction Traffic by Alternative and Construction Phase 5-52
5.7-4. Existing and Projected ADT on Haul Routes for The Rivers APA 5-55
5.7-5. Existing and Projected ADT on Haul Routes for The Rivers APA 5-58
5.8-1. Yolo County and Sacramento County Air Quality Attainment Status 5-62
5.8-2. Construction Phases, Activities, Schedule, and Equipment: The Rivers APA 5-65
5.8-3. Estimated Construction Emissions: The Rivers APA 5-67
5.8-4. Construction Phases, Activities, Schedule, and Equipment: The Rivers Alternative B 5-73
5.8-5. Estimated Construction Emissions: The Rivers Alternative B 5-74
5.9-1. Ambient Noise Survey Results, The Rivers EIP Project Area 5-82
5.9-2. Modeled Construction Noise Levels for The Rivers Applicant Preferred Alternative 5-84
5.9-3. Modeled Construction Noise Levels for The Rivers Alternative B 5-87
5.9-4. Estimated Ground Vibration Levels Caused by Impact Pile Driver 5-89
5.10-1. Arborist Survey Results for The Rivers EIP 5-97
5.12-1. Wildlife Species Observed in The Rivers EIP Study Area 5-114
5.12-2. Special-Status Wildlife Species with Potential to Occur in The Rivers EIP Study Area 5-118
5.12-3. Elderberry Shrub Survey Results—Riparian 5-131
5.15-1. Race/Origin Characteristics by City/County/State, 2000 and 2005 5-150
5.15-2. Household Poverty Status by City/County/State, 2000 5-150
5.18-1. Utilities Located in The Rivers Project Area 5-167
6-1. West Sacramento General Plan Update Alternatives 6-7
6-2. Potential Projects Requesting Section 408 Approval 6-12

5-4 Paved Landing Details for The Rivers 5-16
5.6-1 Soil Types at The Rivers Early Implementation Site 5-42
5.7-1 The Rivers EIP Haul Routes 5-52
5.10-1 Land Cover Types in the Study Area at The Rivers EIP Site 5-94
5.12-1 The Rivers Site: Elderberry Shrub Survey Map 5-126
5.16-1 The Rivers—Photos 1–3 5-154

List of Acronyms and Abbreviations

$\mu g/m^3$	micrograms per cubic meter
µS/cm	microSiemens per centimeter
A.D.	Anno Domini
AADT	annual average daily traffic
AB 32	Assembly Bill 32, the California Global Warming Solutions Act of 2006
AB 75	Assembly Bill 75
AB 939	Assembly Bill 939
ACHP	Advisory Council on Historic Preservation
ADA	Americans with Disabilities Act
ADT	Average daily traffic
AEP	annual exceedance probability
AEPs	Annual Exceedance Probabilities
af	acre-feet
AG	California Attorney General
Alquist-Priolo Act	Alquist-Priolo Earthquake Fault Zoning Act
APA	Applicant Preferred Alternative
APE	area of potential effect
ASTM	American Society for Testing and Materials
B.P.	Before Present
BA	biological assessment
BAAQMD	Bay Area Air Quality Management District
Basin Plan	Water Quality Control Plan
bgs	below ground surface
BMPs	best management practices
BNSF	Burlington Northern Santa Fe Railroad
BO	biological opinion
BOD	biochemical oxygen demand
BSSCP	bentonite slurry spill contingency plan
BTEX	benzene, toluene, ethylbenzene, and total xylenes
CAA	Clean Air Act
CAAQS	California Ambient Air Quality Standards
$CaCO_3$	calcium carbonate
CalEPA	California Environmental Protection Agency
Caltrans	California Department of Transportation
CAPCOA	California Air Pollution Control Officers Association
CARB	California Air Resources Board
Carl Moyer Program	Carl Moyer Memorial Air Quality Standards Attainment Program
CAT	Climate Act Team

CBSC	California Building Standards Code
CCAA	California Clean Air Act
CCR	California Code of Regulations
CDEC	California Data Exchange Center
CEQ	Council on Environmental Quality
CEQA	California Environmental Quality Act
CESA	California Endangered Species Act
CFGC	California Fish and Game Code
CFR	Code of Federal Regulations
cfs	cubic feet per second
City	City of West Sacramento
CIWMP	Countywide Integrated Waste Management Plan
CNDDB	California Natural Diversity Database
CNEL	community noise equivalent level
CNG	compressed natural gas
CNPPA	California Native Plant Protection Act of 1977
CNPS	California Native Plant Society
CO	carbon monoxide
CO_2	carbon dioxide
Common Features	American River Common Features Project
Comp Study	Sacramento and San Joaquin River Basins Comprehensive Study
Comprehensive Study	Sacramento and San Joaquin River basins California Comprehensive Study
CO-OPS	NOAA Center for Operational Oceanographic Products and Services
CPTs	cone penetration test equipment
CPUC	California Public Utilities Commission
CRHR	California Register of Historic Resources
CTR	California Toxics Rule
CVFPB	Central Valley Flood Protection Board
CVFPP	Central Valley Flood Protection Plan
CVP	Central Valley Project
CWA	Federal Clean Water Act
cy	cubic yards
dB	decibel
dBA	A-weighted decibel
Delta	Sacramento–San Joaquin River Delta
DFG	California Department of Fish and Game
DIPE	di-isopropyl ether
DO	dissolved oxygen
DPM	diesel particulate matter
DPSs	distinct population segments
DSM	deep soil mixing
DWR	California Department of Water Resources

DWSC	Sacramento Deep Water Ship Channel
EB	eastbound
EC	Electrical conductivity
EFH	essential fish habitat
EIPs	early implementation projects
EIS/EIR	Environmental Impact Statement/Environmental Impact Report
EPA	U.S. Environmental Protection Agency
ESA	Endangered Species Act
ETBE	ethyl tertiary butyl ether
ETL	Engineering Technical Letter
FEMA	Federal Emergency Management Agency
FHWA	Federal Highway Administration
FIRM	Flood Insurance Rate Map
Flood Control Project	Sacramento River Flood Control Project
FMMP	Farmland Mapping and Monitoring Program
FPPA	Farmland Protection Policy Act
FR	Federal Register
ft/s	feet per second
ft^2	square feet
General Construction Permit	General Permit for Construction Activities
GHGs	Greenhouse Gases
GIS	geographic information system
GPS	geographic positioning system
GRR	West Sacramento General Reevaluation Report
H	horizontal feet
HABS/HAER	Historic American Building Survey/Historic American Engineering Record
HAPs	hazardous air pollutants
HEP	Habitat Evaluation Procedure
HPMP	Historic Properties Management Plan
I-5	Interstate 5
I-80	Interstate 80
in/sec	inches per second
L_{dn}	day-night sound level
L_{eq}	equivalent sound level
LF	less favorable
LIDAR	Light Detection and Ranging
L_{min} and L_{max}	minimum and maximum sound levels
LNG	liquefied natural gas
LOS	Level of service

L_{xx}	percentile-exceeded sound levels
m/km	meters/kilometer
Magnuson-Stevens Act	Magnuson-Stevens Fishery Conservation and Management Act
MBTA	Migratory Bird Treaty Act
MDPS	Main Drain Pump Station
MF	more favorable
mg/L	milligrams per liter
MOA	memorandum of agreement
MOU	memorandum of understanding
MRZ	mineral resource zone
MTBE	methyl tertiary butyl ether
NAAQS	National Ambient Air Quality Standards
NAHC	Native American Heritage Commission

Chapter 1
Introduction

The West Sacramento Area Flood Control Agency (WSAFCA) is proposing the West Sacramento Levee Improvements Program (WSLIP or the program) to improve the levees in Yolo and Solano Counties that protect the city of West Sacramento.

To protect human health and safety and prevent adverse effects on property and its economy, the City of West Sacramento (City), as part of WSAFCA, and in partnership with the California Department of Water Resources (DWR), embarked on a comprehensive evaluation of the condition of the levees protecting the city in 2006 (HDR, Inc. 2008). The evaluation was necessary to determine the level of flood protection provided by the existing levee system, identify the magnitude and severity of deficiencies, and propose potential levee improvements. The results of the comprehensive evaluation revealed several deficiencies that require substantial improvements to meet current flood protection standards. *Note: In this document, "city" (lowercase) refers to the area of West Sacramento while "City" (capitalized) refers to governmental entity of West Sacramento. "West Sacramento" is also used in some instances, typically referring to the geographic area.*

To implement the proposed improvements, WSAFCA is requesting permission from the U.S. Army Corps of Engineers (USACE) pursuant to Section 14 of the Rivers and Harbors Act of 1899 (Title 33 of the United States Code [USC], Section 408, [33 USC 408]), hereinafter referred to as Section 408, for the alteration of the Federal flood control project; authority under Section 404 of the Federal Clean Water Act (CWA) (33 USC 1344) for the placement of fill or dredged material into jurisdictional waters of the United States; and authority under Section 10 of the Rivers and Harbors Act (33 USC 403) where work would be performed in, under, or over navigable waters. USACE must grant permission for the project pursuant to Section 408, Section 404, and Section 10, triggering the requirement for USACE to comply with the National Environmental Policy Act (NEPA). A more detailed discussion of relevant laws, policies, plans, and regulations is included in Chapter 7, Compliance with Applicable Laws, Policies, and Plans and Regulatory Framework.

In light of the flood risk to West Sacramento, WSAFCA is taking proactive measures to reduce risk and improve the level of flood protection for the city. Specifically, the WSLIP and the early implementation projects (EIPs) (described in 1.5) under the program are targeted to reduce risk and are proposed in sponsorship by WSAFCA in advance of USACE's project being studied under the West Sacramento General Reevaluation Report (GRR). As described in 1.6.1.1.2, USACE is preparing a West Sacramento GRR. As the GRR is not scheduled for completion until 2012 to in turn allow improvements in successive years, the WSLIP is being advanced by WSAFCA to facilitate EIPs to more immediately address flood risk before the GRR is complete. The WSLIP program evaluation and EIPs are intended to be consistent and compatible with the final West Sacramento GRR. Except for EIPs constructed in advance of the GRR, the WSLIP improvements would be substantially implemented through the GRR once in place. The GRR will include independent NEPA review from the WSLIP; however, the processes are being coordinated for consistency and efficiency.

1.1 Document Purpose and Structure

1.1.1 Document Overview

This document is a joint program and project Environmental Impact Statement/Environmental Impact Report (EIS/EIR) and is intended to satisfy the requirements of NEPA and the California Environmental Quality Act (CEQA) for disclosing environmental effects and recommended mitigation measures related to a proposed action, and alternatives, prior to making a decision on project approval. A "joint" EIS/EIR means that the NEPA lead agency (USACE) and the CEQA lead agency (WSAFCA) are each making a decision on a proposed action and have agreed to analyze the effects of that action in the same environmental document.

Specifically, this document provides program-level analysis for the WSLIP to support project-level analysis and decision-making for EIPs. Two EIPs are described and analyzed at the project level to support a NEPA Record of Decision (ROD) and CEQA Notice of Determination (NOD). These EIPS are at the CHP Academy site and The Rivers site, described more fully in Chapters 4 and 5, respectively. It is anticipated that analysis of future EIPs will be subsequently tiered from this document. The purpose of program-level analysis is to describe the planning context for the project-level actions and provide thorough consideration of cumulative, indirect, and growth-inducing effects. All sections of this EIS/EIR support the program- and project-level analyses; however, project-level details are focused in Chapters 4 and 5 where available and applicable.

This section provides guidance for "how to" read and interpret the EIS/EIR, including the following elements:

- document organization;
- background of NEPA and CEQA requirements;
- NEPA and CEQA lead agency roles;
- use of a combined document for NEPA and CEQA compliance;
- use of NEPA and CEQA terminology;
- resource analysis structure, including relationship of program and project analyses; and
- discussion of vertical datum used in this document.

1.1.2 Document Organization

This EIS/EIR is organized into the following sections:

- Executive Summary
- List of Acronyms and Abbreviations
- Chapter 1, Introduction
- Chapter 2, Alternatives
- Chapter 3, Affected Environment and Environmental Consequences
- Chapter 4, CHP Academy Early Implementation Project
- Chapter 5, The Rivers Early Implementation Project

- Chapter 6, Growth-Inducing and Cumulative Effects
- Chapter 7, Compliance with Applicable Laws, Policies, Plans, and Regulatory Framework
- Chapter 8, References
- Chapter 9, List of Preparers
- Chapter 10, List of Recipients
- Index
- Appendix A, Scoping Report
- Appendix B, U.S. Army Corps of Engineers Interim Vegetation Guidance for Control of Vegetation on Levees
- Appendix C, Supporting Documents, Figures, and Tables for Geomorphology and Flood Control
- Appendix D, Utility Assessment for Basin-Wide Problem Identification Report, HDR, Inc.
- Appendix E, Air Quality Information
- Appendix F, Plant Lists
- Appendix G, Correspondence Regarding Special-Status Species
- Appendix H, Public Health and Hazards: EDR Data Map Environmental Atlas
- Appendix I, Correspondence Regarding Cultural Resources

1.1.3 NEPA and CEQA Requirements

The Council on Environmental Quality's (CEQ's) regulations for implementing NEPA specify that a Federal agency preparing an EIS must consider the effects of the proposed action and alternatives on the environment; these include effects on ecological, aesthetic, historical, and cultural resources and economic, social, and health effects. Environmental effects are categorized as direct, indirect, and cumulative. An EIS also must discuss possible conflicts with the objectives of Federal, state, regional, and local land use plans, policies, or controls for the area concerned; energy requirements and conservation potential; urban quality; the relationship between short-term uses of the environment and long-term productivity; and irreversible or irretrievable commitments of resources. An EIS must identify relevant, reasonable mitigation measures not already included in the proposed action or alternatives that could avoid, minimize, rectify, reduce, eliminate, or compensate for the project's adverse environmental effects. (40 Code of Federal Regulations [CFR] 1502.14, 1502.16, and 1508.8.)

The CEQA Guidelines explain that the environmental analysis for an EIR must evaluate impacts associated with the project and identify mitigation for any potentially significant impacts. All phases of a proposed project, including construction and operation, are evaluated in the analysis. Section 15126.2 of the State CEQA Guidelines states:

> An EIR shall identify and focus on the significant environmental effects of the proposed project. In assessing the impact of a proposed project on the environment, the lead agency should normally limit its examination to changes in the existing physical conditions in the affected area as they exist at the time the notice of preparation is published, or where no notice of preparation is published, at the time environmental analysis is commenced. Direct and indirect significant effects of the project on the environment shall be clearly identified and described, giving due consideration to both the

short-term and long-term effects. The discussion should include relevant specifics of the area, the resources involved, physical changes, alterations to ecological systems, and changes induced in population distribution, population concentration, and human use of the land (including commercial and residential development), health and safety problems caused by the physical changes, and other aspects of the resource base such as water, historical resources, scenic quality, and public services. The EIR shall also analyze any significant environmental effects the project might cause by bringing development and people into the area affected.

An EIR also must discuss inconsistencies between the proposed project and applicable general plans and regional plans (State CEQA Guidelines Section 15125[d]).

An EIR must describe any feasible measures that could minimize significant adverse impacts, and the measures are to be fully enforceable through permit conditions, agreements, or other legally binding instruments (State CEQA Guidelines Section 15126.4[a]). Mitigation measures are not required for effects that are found to be less than significant.

1.1.3.1 NEPA Lead Agency

USACE is the lead agency preparing this EIS for the purposes of compliance with NEPA. As stated above, USACE maintains authority pursuant to Section 14 of the Rivers and Harbors Act of 1899 (33 USC 408), for the alteration of a Federal project; authority under Section 404 of the Federal CWA (33 USC 1344) for the placement of fill or dredged material into jurisdictional waters of the United States; and authority under Section 10 of the Rivers and Harbors Act (33 USC 403) where work would be performed in, under, or over navigable waters. Under NEPA and the CEQ's NEPA regulations (40 CFR 1500 *et seq*.), Federal agencies are required to evaluate the environmental effects of an action, including feasible alternatives, and identify mitigation measures to minimize adverse effects when they propose to carry out, approve, or fund a project that may have a significant effect on the environment. USACE has determined that its involvement in the WSLIP, including its authority over alterations to Federal project levees, requires compliance with NEPA and preparation of an EIS.

1.1.3.2 CEQA Lead Agency

WSAFCA is the lead agency preparing this EIR for the purposes of compliance with CEQA. WSAFCA is a Joint Powers Authority created in 1994 through a Joint Exercise of Powers Agreement by the City, Reclamation District 900 (RD 900), and Reclamation District 537 (RD 537). WSAFCA was established to coordinate the planning and construction of flood protection facilities and to finance the local share of flood control projects. WSAFCA's member agencies are responsible for the operations and maintenance of the detention basins, pump stations, and levees that protect the city.

Pursuant to Section 15126(d) of the State CEQA Guidelines, an EIR must describe and evaluate a reasonable range of alternatives that would feasibly attain most of the basic project objectives and would avoid or substantially lessen any significant impact of the project as proposed.

1.1.3.3 Combined Program and Project Environmental Impact Statement/ Environmental Impact Report

In addition to being a joint EIS/EIR, this document is a combined program- and project-level EIS/EIR. The WSLIP is a program of levee improvements that will be implemented over 10 to 15 years, perhaps longer, with reach- or deficiency-specific components that are proposed for implementation in the short term (as soon as 2011). A program EIS/EIR analyzes the broad

environmental effects of a program with the acknowledgment that more detailed analysis may be required for components of the program when those components are proposed for implementation and greater specificity is known. Program review provides a forum for discussing combined and cumulative effects of individual projects (projects both internal and external to the program), thereby avoiding segmentation. Two of the WSLIP components are proposed for construction as soon as 2011, and details are sufficiently developed to enable a site-specific environmental analysis at a level of detail sufficient for USACE and WSAFCA to support a decision of approval. Therefore, the program and project analyses are being combined into one document to communicate the program and project context in a transparent manner, disclose available information, and facilitate efficient analysis and review.

Both NEPA and CEQA provide guidelines for the preparation of a program EIS/EIR. A program EIS/EIR is prepared for an agency program or series of actions that typically are connected by one or more of the following characteristics:

- are linked geographically (same general location, region, or the same body of water) and could be characterized as one large project;
- involve rules, regulations, plans, or other general criteria to govern the conduct of a continuing program;
- have individual activities carried out under the same authorizing statutory or regulatory authority; and
- have actions that have relevant similarities, such as common timing, effects, alternatives, methods of implementation, media, or subject matter (State CEQA Guidelines Section 15168, and 40 CFR Section 1508).

USACE and WSAFCA have determined that this combined and joint EIS/EIR is the most appropriate means to comply with both NEPA and CEQA because of the need to coordinate among Federal and state agencies, and the need to complete environmental review as expeditiously as possible. This document incorporates environmental review required under multiple Federal, state, and local permits and regulations (Chapter 7, Compliance with Applicable Laws, Policies, and Plans and Regulatory Framework).

1.1.4 Application of NEPA and CEQA Principles and Terminology

NEPA and CEQA are similar in that both laws require the preparation of an environmental study to evaluate the environmental effects of proposed government activities. However, there are several differences between the two regarding terminology, procedures, environmental document content, and substantive mandates to protect the environment. For this environmental evaluation, the more rigorous of the two laws was applied in cases in which NEPA and CEQA differ.

Table 1-1 below compares the terminology of NEPA and CEQA for common concepts.

Table 1-1. Key to General NEPA and CEQA Terminology

NEPA Term	Correlating CEQA Term
Lead Agency	Lead Agency
Cooperating Agency	Responsible Agency
Environmental Impact Statement	Environmental Impact Report
Record of Decision	Findings
Preferred Alternative	Proposed Project
Project Purpose	Project Objectives
No Action Alternative	No Project Alternative
Affected Environment	Environmental Setting
Effect	Impact

In some cases in this document, both NEPA and CEQA terminology are used, as in Chapter 1 where the project purpose and need and project objectives are discussed. The terms *environmental consequences, environmental impacts,* and *environmental effects* are considered synonymous in this analysis, and *effects* is used for consistency.

Technical terms used in the EIS/EIR are typically defined in their first instance of use in the text. A list of acronyms and abbreviations precedes Chapter 1.An index follows Chapter 10.

1.1.5 Resource Analysis Structure

The resource sections in Chapter 3 contain the affected environment and environmental consequences analysis (outlined in detail below) at the program level. Chapters 4 and 5 contain the project-level analysis. In most cases, the program-level information such as the affected environment, analysis methods, and determination of effects also applies to the project-level analysis in Chapters 4 and 5. Therefore, rather than entirely repeating that information, the relevant text is summarized in Chapters 4 and 5 and the reader is referred to the information as discussed under the program in Chapter 3.

- **Introduction.** This section introduces the scope of the resource analysis.
    - **Sources of Information.** This section lists the sources of information pertinent to the analysis of project and program impacts on this specific resource.
- **Affected Environment.** This section includes two sections, Regulatory Setting and Environmental Setting.
    - **Regulatory Setting.** This section lists and describes laws, regulations and policies that affect the resource or the assessment of effects on the resource. Often the regulatory framework is the basis for the conclusion of the level of significance and therefore plays a crucial role in effect assessment.
    - **Environmental Setting.** This section provides an overview of the physical environmental conditions in the area at the time of or prior to the publication of the Notice of Preparation that could be affected by implementation of the proposed alternatives in accordance with NEPA regulations (40 CFR 1502.15) and State CEQA Guidelines Section 15125.

- **Environmental Consequences.** This section describes the analysis of effects relating to each resource area for each of the alternatives in accordance with NEPA regulations (40 CFR 1502.16) and with State CEQA Guidelines Section 15126, 15126.2, and 15143.
    - **Assessment Methods.** This section describes the methods, models, process, procedures, data sources, and/or assumptions used to conduct the effect analysis. Where possible, effects are evaluated quantitatively. Where quantification is not possible, effects are evaluated qualitatively.
    - **Determination of Effects.** This section provides the criteria used in this document to define the level at which an effect would be considered significant in accordance with CEQA and adverse in accordance with NEPA. Significance criteria (sometimes called thresholds of significance) used in this EIS/EIR are based on the checklist presented in Appendix G of the State CEQA Guidelines; factual or scientific information and data; and regulatory standards of Federal, state, and local agencies. Under NEPA, preparation of an EIS is triggered if a Federal action has the potential to "significantly affect the quality of the human environment," which is based on the context and intensity of each potential effect. The significance thresholds used in this EIS/EIR also encompass the factors taken into account under NEPA to evaluate the context and the intensity of the effects of an action.
    - **Effects and Mitigation Measures.** To comply with NEPA and CEQA, the effects/impacts are considered and evaluated as to whether they are direct, indirect, or cumulative. Direct effects are those that are caused by the action and occur at the same time and place. Indirect effects are reasonably foreseeable consequences to the physical environment that may occur at a later time or at a distance from the project area. Because direct and indirect effects are often interrelated, typically there is no distinction made between the two in the effects discussion. Cumulative effects for all resource areas are combined and discussed in Chapter 6, Growth-Inducing and Cumulative Effects.

      The effects are listed numerically and sequentially throughout each section. An effect statement precedes the discussion of each effect and provides a summary of the effect topic. The numbering system provides a mechanism for tracking unique effects by resource area. The numeric assignations at the program level in Chapter 3 are applied to the project-level analyses in Chapters 4 and 5, supported by additional details as needed.

      Each effect is accompanied by a finding or conclusion, as required under NEPA and CEQA. Table 1-2 provides a key for relating the effect findings by relative severity (increasing in degree of adversity to the environment).

Table 1-2. Key to Effect Findings (by increasing adversity)

Finding
Beneficial
No Effect
Less than Significant
Significant
Significant and Unavoidable

For the purposes of the analyses in this document, the effect findings are defined more specifically below.

- **Beneficial.** This effect would provide benefit to the environment as defined for that resource.
- **No Effect.** This effect would cause no discernible change in the environment as measured by the applicable significance criterion; therefore, no mitigation would be required.
- **Less than Significant.** This effect would cause no substantial adverse change in the environment as measured by the applicable significance criterion; therefore, no mitigation would be required.
- **Significant.** This effect would cause a substantial adverse change in the physical conditions of the environment. Effects determined to be significant based on the significance criteria fall into two categories: those for which there is feasible mitigation available that would avoid or reduce the environmental effects to less-than-significant levels and those for which there is either no feasible mitigation available or for which, even with implementation of feasible mitigation measures, there would remain a significant adverse effect on the environment. Those effects that cannot be reduced to a less-than-significant level by mitigation are identified as significant and unavoidable, described below.
- **Significant and Unavoidable**. This effect would cause a substantial adverse change in the environment that cannot be avoided or mitigated to a less-than-significant level if the program is implemented. Even if the effect finding is still considered significant with the application of mitigation, the applicant is obligated to incorporate all feasible measures to reduce the severity of the effect.
- **Mitigation Measures.** Measures to mitigate (i.e., avoid, minimize, rectify, reduce, eliminate, or compensate for) significant effects accompany each effect discussion. Similar to the effect descriptions, mitigation measures are listed numerically and sequentially throughout each section. A mitigation measure statement precedes the discussion of each measure and provides a summary of the measure topic. The numbering system provides a mechanism for tracking unique measures by resource area. The numeric assignations at the program level in Chapter 3 are applied to the project-level analyses in Chapters 4 and 5, supported by additional details as needed.

1.1.6 Elevation Datum Used in This Document

Elevations used in this document are referenced to the North American Vertical Datum of 1988 (NAVD 88) to the greatest extent feasible. It should be noted that many of the studies cited in the alternatives descriptions and analyses were originally conducted in the National Geodetic Vertical Datum of 1929 (NGVD 29) and have been converted where feasible. In some cases, such as where a figure has been borrowed from another study, the elevations have not been converted to preserve the integrity of the source study.

1.2 WSLIP Regional Setting and Study Area

The regional setting of the WSLIP is the Sacramento River Flood Control Project (SRFCP), beginning as far north as Redding, California, and extending south to the Sacramento–San Joaquin River Delta (Delta) (Figure 1-1). For the analysis of effects (direct, indirect, or cumulative), the regional context of the SRFCP is taken into consideration.

The WSLIP study area refers to the area that would be protected by the proposed levee improvements, including the city of West Sacramento itself and the lands within WSAFCA's boundaries, which encompass portions of the Sacramento River, the Yolo Bypass, the Sacramento Bypass, and the Sacramento Deep Water Ship Channel (DWSC). The flood protection system associated with these waterways consists of over 50 miles of levees in RD 900, RD 537, DWR's Maintenance Area 4, and the DWSC (Figure 1-2). These levees completely surround the city with the exception of intersecting waterways. For the purposes of this program, the levees surrounding the city have been divided into nine subreaches, as shown on Figure 1-2. These reaches are described in detail in Section 1.2.1, WSLIP Study Reaches and Potential Construction Footprint.

The city of West Sacramento is located in eastern Yolo County at the confluence of the American and Sacramento Rivers. The city lies within the natural floodplain of the Sacramento River, which bounds the city along the east. It is made up of reclaimed land protected from floods by levees and the Yolo and Sacramento Bypass systems. These bypasses divert floodflows around the city to the west. In addition to the area within the city limits (in Yolo County), the study area partially extends into Solano County on the extreme southwestern edge along the DWSC. Therefore, resources in Solano County have the potential to be affected by the WSLIP and these are described on a resource-specific basis.

The DWSC and barge canal bisect the city into two subbasins, separating the developing Southport area from the more established neighborhoods of Broderick and Bryte to the north (City of West Sacramento 2000). The DWSC provides a navigable passageway for commercial shipping to reach the Port of West Sacramento (formerly Port of Sacramento) from the Pacific Ocean via the San Francisco Bay, Delta, and connecting waterways. The DWSC water surface elevation is directly influenced by changes in water levels in the Delta at the south end of the Yolo Bypass and is relatively insensitive to stage in the Sacramento River. The barge canal and lock system, formerly a Federal facility but now de-authorized, were constructed to provide a navigable, gated connection between the Port of West Sacramento and the Sacramento River, but no longer functions for navigability because the channel approaches have silted in from naturally deposited sediment and because a fixed roadway crossing precludes passage of any commercial vessel.

The area that would be protected by the WSLIP—the city of West Sacramento—is the metropolitan area most downstream within the SRFCP, along with the city of Sacramento across the Sacramento River on the left bank. *Note: All levees, reaches, and landmarks are referred to using river navigation terminology. Left bank and right bank refer to locations when facing downstream in the direction of flow.* The downstream location of the study area is important relative to other flood risk reduction projects occurring upstream within the SRFCP, namely, the American River Common Features Project, Natomas Levee Improvement Program, projects undertaken by the Three Rivers Levee Improvement Authority, the Sutter Basin Project, and the Yuba Basin Project (Figure 1-3). These and other projects are described under Section 1.6, Related Actions, Programs, and Planning Efforts.

As introduced above, the WSLIP area is partly within the Delta. Specifically, the study area is within the bounds of the Legal Delta as defined by the State of California under the Delta Protection Act (Section 12220 of the Water Code). The Legal Delta is further subdivided into a primary zone and secondary zone for land use planning and resource protection purposes. Most of West Sacramento is in the secondary zone, while the extreme northern part of the city is outside of any of these Delta planning areas. The study reach described below (1.2.1.8) along the DWSC West Levee is the only portion of the study area within the primary zone. *Note: The WSLIP is consistent with these designations, land use planning, and resource protection for the Delta and this issue is not discussed further in the EIS/EIR.*

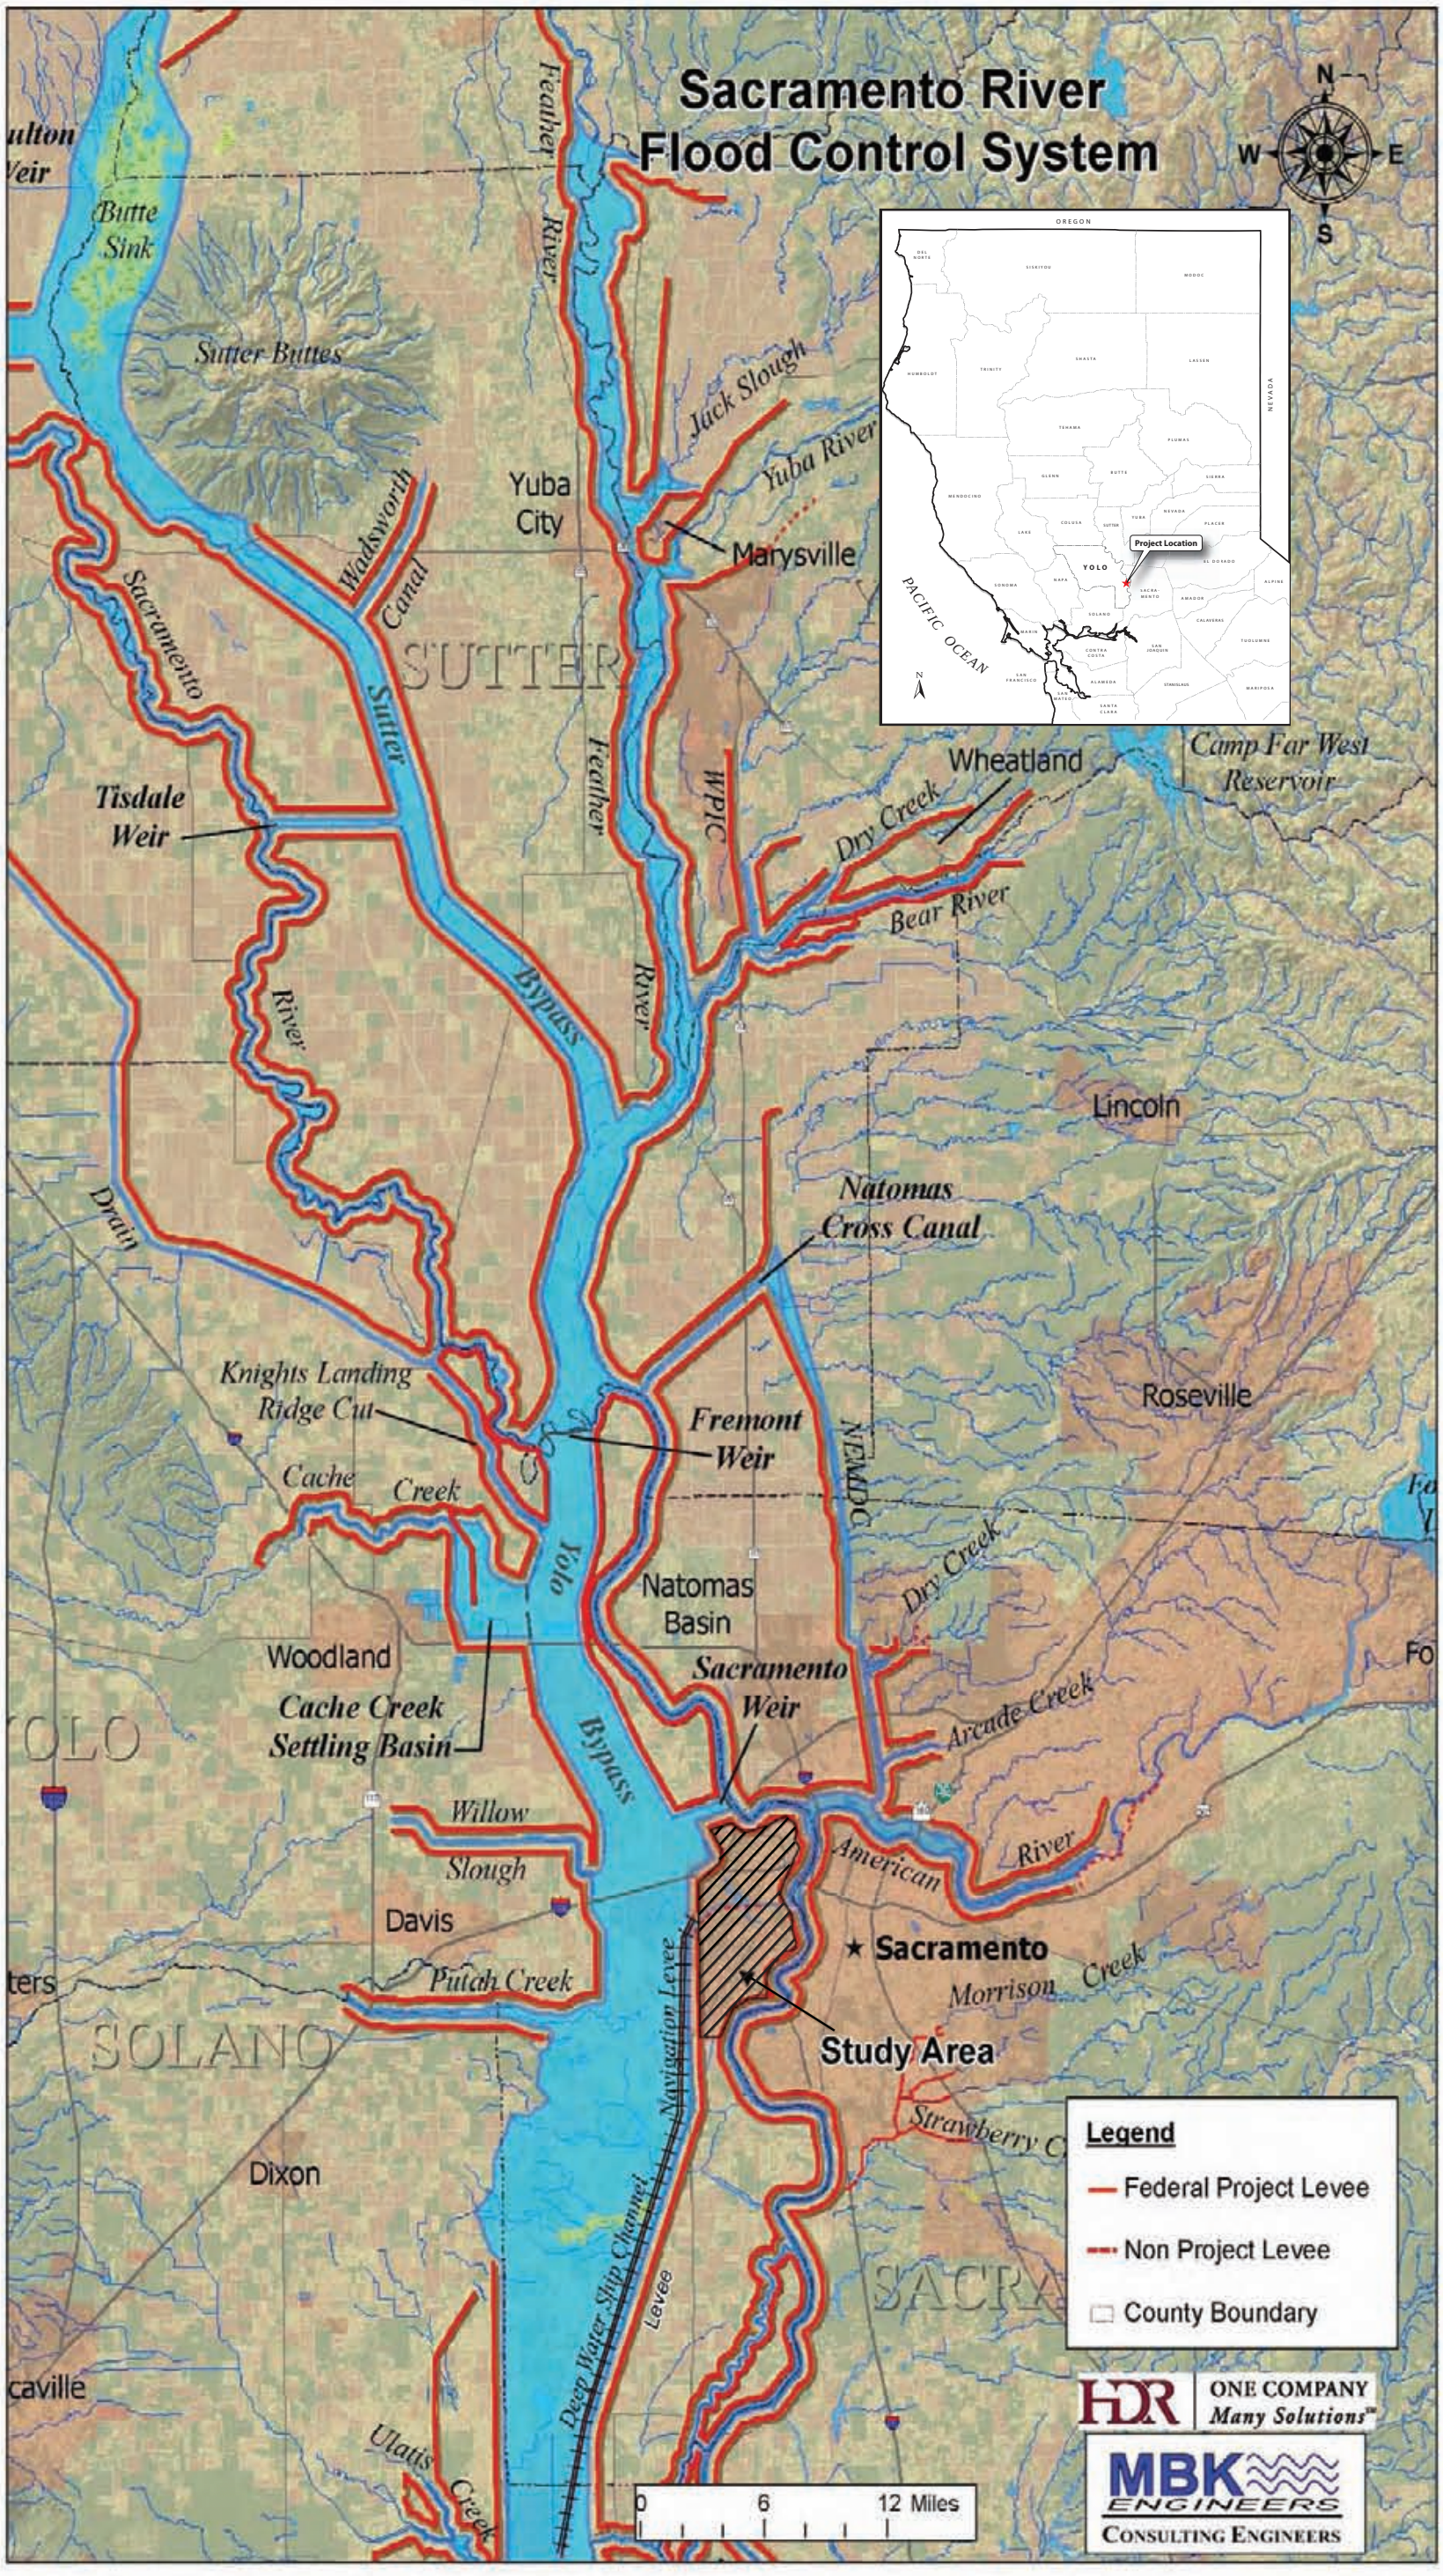
1.2.1 WSLIP Study Reaches and Potential Construction Footprint

Building on the general description of the study area, each of the nine reaches in the study area is detailed below. For the environmental analysis of most resources in this EIS/EIR, the potential construction footprint area where proposed improvements and resulting effects would occur is generally a 520-foot-wide corridor along each levee reach, assumed to conservatively include any potential improvements. The reaches and potential construction footprint area are shown in Figure 1-4.

1.2.1.1 Sacramento Bypass Levee

This reach extends along the left bank of the Sacramento Bypass approximately 1.2 miles from the Sacramento Weir in a westerly direction (downstream) to its confluence with the left bank levee of the Yolo Bypass. This reach does not include the training levee that extends in a westerly direction approximately 0.4 mile into the Yolo Bypass (Figure 1-5).

1.2.1.2 Sacramento River North Levee



This reach extends along the right bank of the Sacramento River from its confluence with the Sacramento Bypass downstream approximately 6.0 miles to the entrance of the barge canal (Figure 1-6).

1.2.1.3 Sacramento River South Levee

This reach extends along the right bank of the Sacramento River from the entrance of the barge canal downstream approximately 6.4 miles to the South Cross Levee (Figure 1-7).

1.2.1.4 Port North Levee

This reach encompasses the combination of levees, structures, and high ground that exists along the right bank of the barge canal and DWSC from the Sacramento River westward to the levee along the left bank of the Yolo Bypass. This area includes the ground surrounding the Port of West Sacramento's turning basin (Figure 1-8).

00875.07 EIS (7-09)

Figure 1-1
Sacramento River Flood Control Project and Regional Setting for the WSLIP Study Area

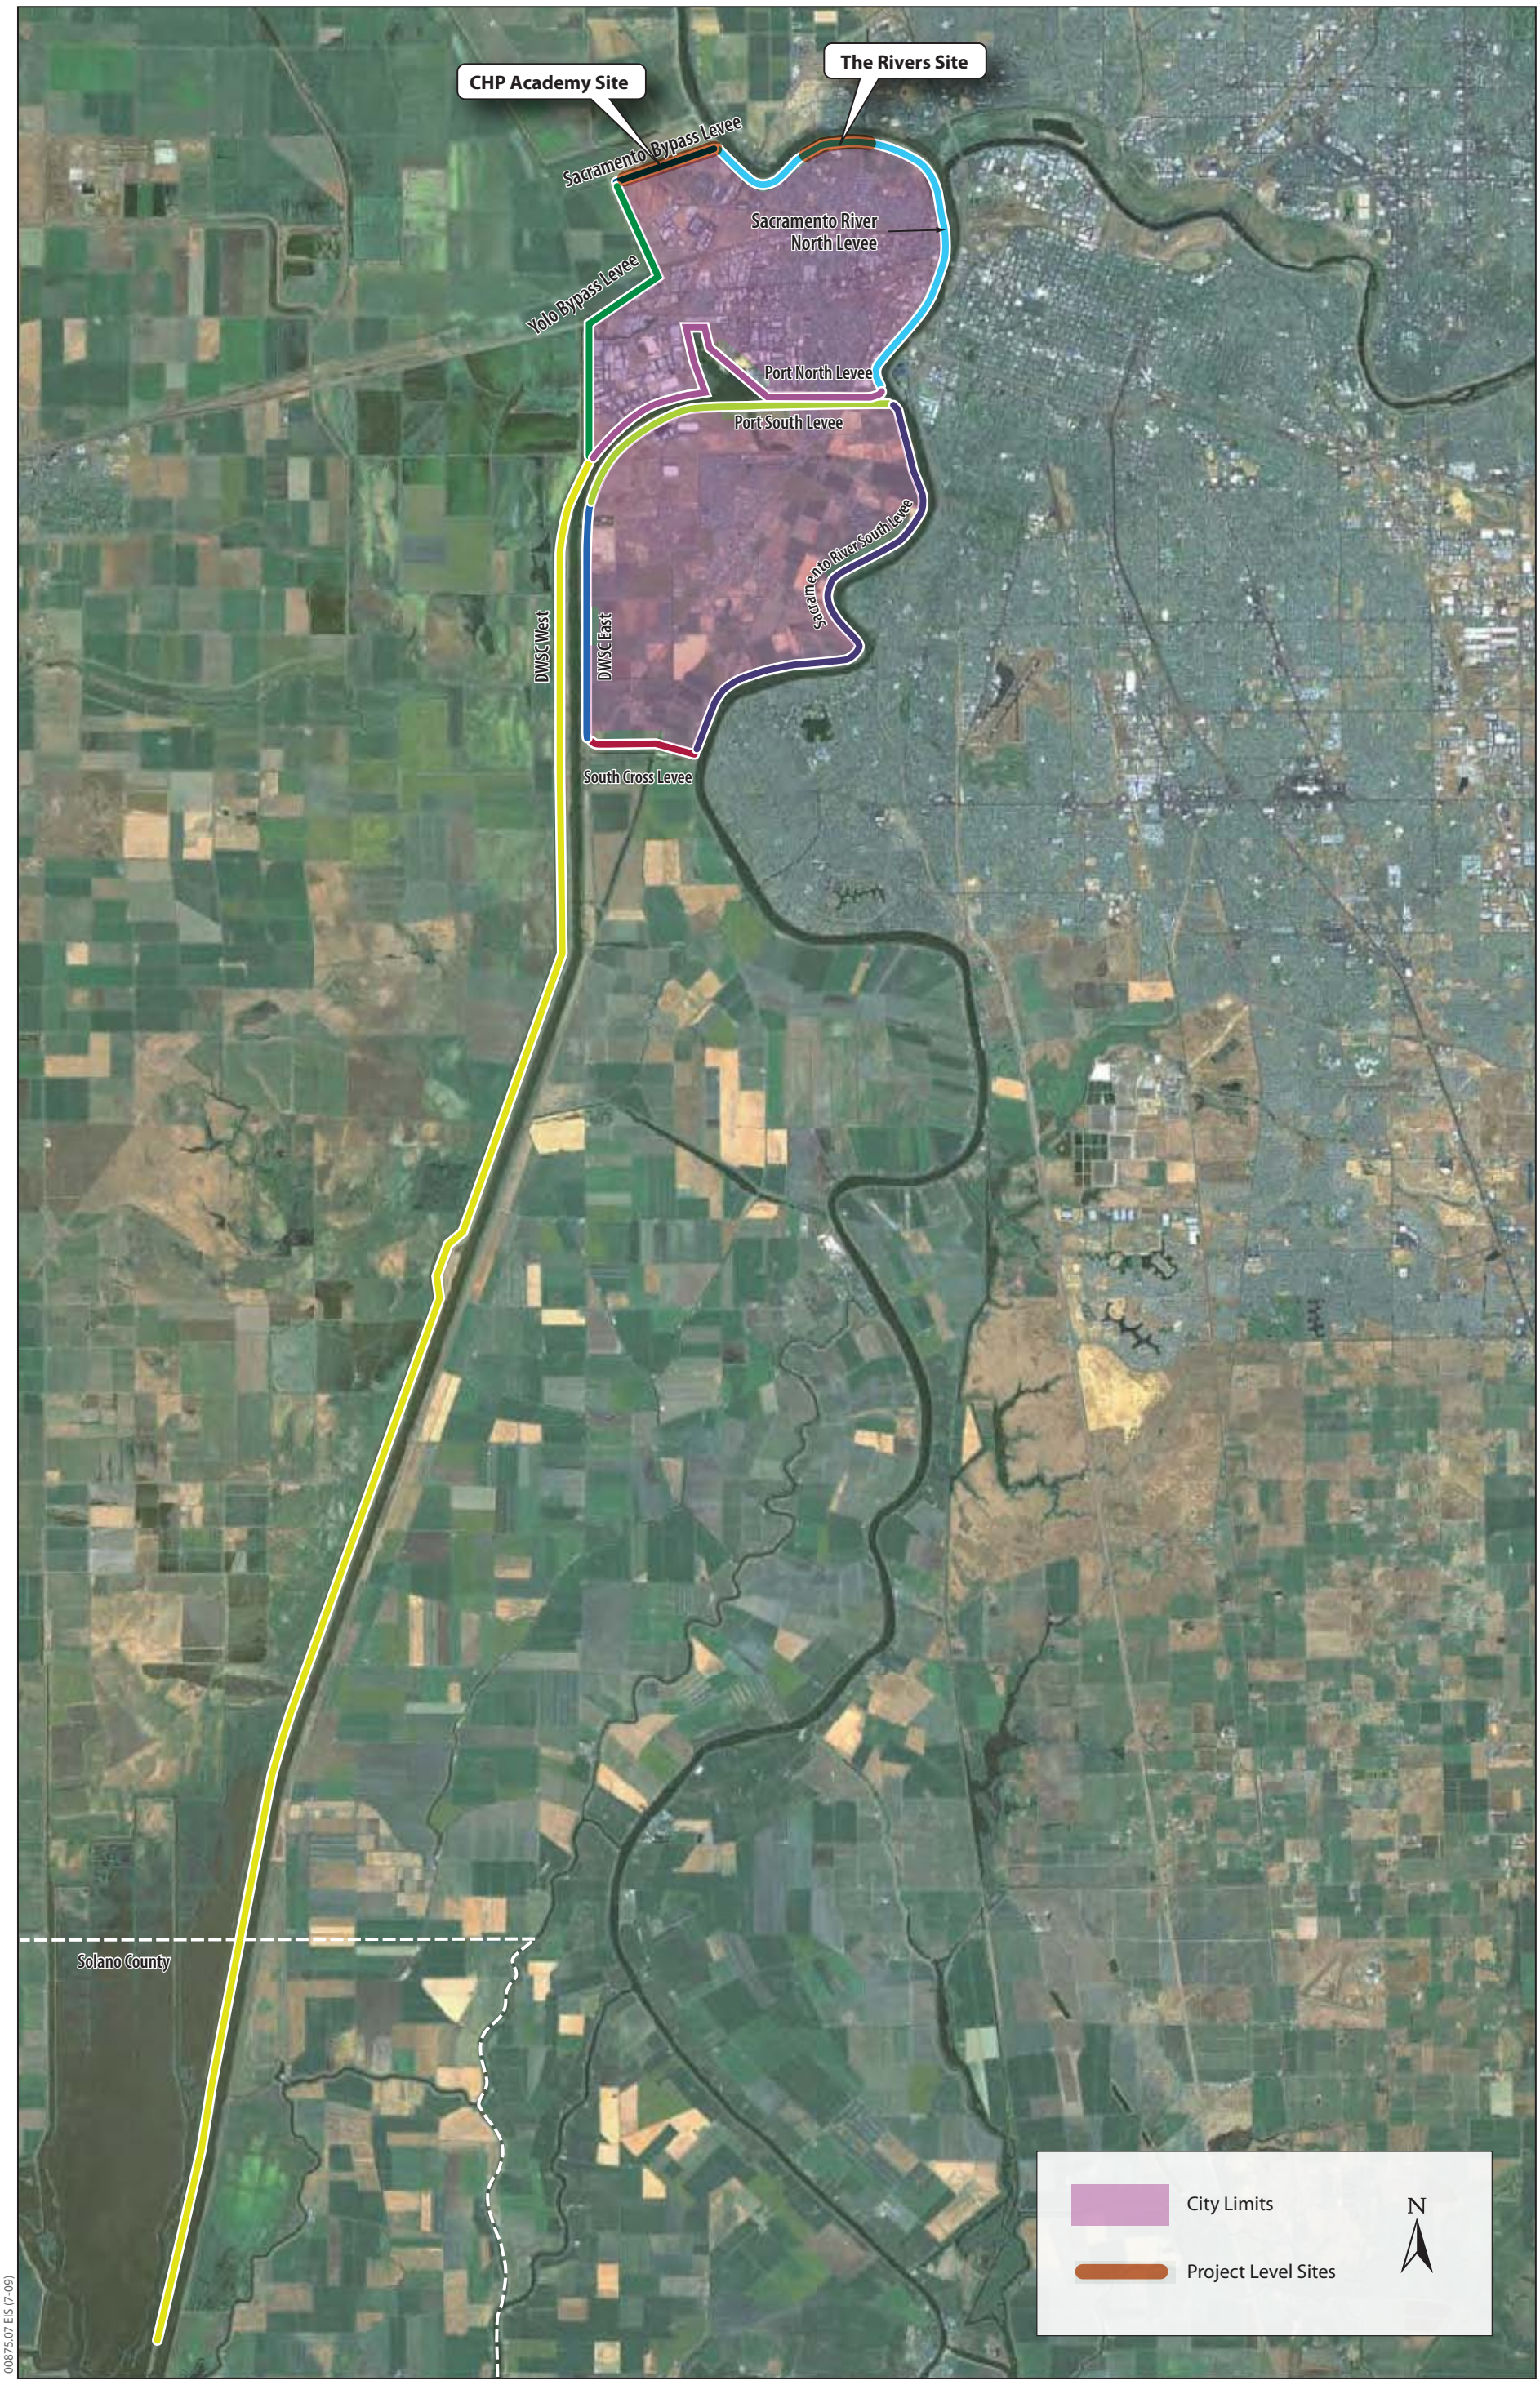


Figure 1-2
WSLIP Study Area

State Plan of Flood Control

Lead Agency: DWR
Location: Central Valley
Goal: Guide flood management expenditures under Propositions 84 & 1E
Timeline: Complete Plan by 2014

Sacramento – San Joaquin River Basins Comprehensive Study

Lead Agency: USACE and DWR
Location: Central Valley
Goal: Flood damage reduction and ecosystem restoration
Phase: Study completed in 2002; laid groundwork for several current efforts, including State Plan of Flood Control

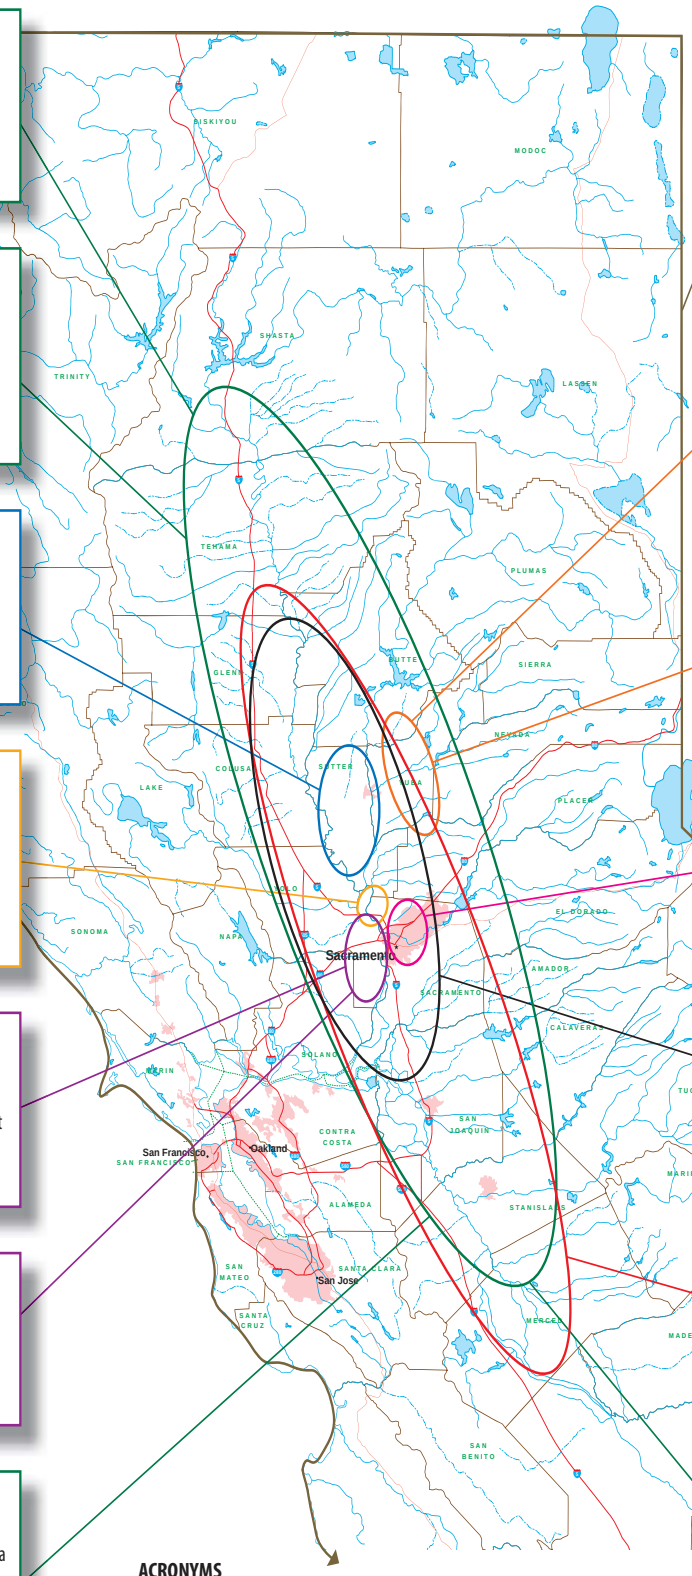
Sutter Basin Project

Lead Agency: USACE and SBFCA
Location: Sutter and Butte counties
Goal: Increase flood protection for communities in Sutter and Butte counties
Phase (Timeline): Feasibility Study and EIS (2011)

Natomas Levee Improvement Program

Lead Agency: SAFCA
Location: Natomas Area, Sacramento
Goal: Achieve 200-year flood protection for the Natomas Basin
Timeline: Construction of 100-year protection by 2011, 200-year protection by 2012

West Sacramento Levee Improvements Project



Lead Agency: USACE and WSAFCA
Location: West Sacramento
Goal: Achieve 200-year flood protection for the City of West Sacramento
Phase (Timeline): EIS/EIR (2010)

West Sacramento Project

Lead Agency: WSAFCA, USACE and DWR
Location: West Sacramento
Goal: Comprehensive analysis of the City's levee system
Phase (Timeline): GRR (2012)

Central Valley Flood Protection Plan

Lead Agency: DWR
Location: Central Valley and Sacramento-San Joaquin Delta
Goal: Develop strategies for comprehensive system-wide flood improvements
Timeline: Complete plan by 2012; complete protection measures by 2025

FloodSAFE

Lead Agency: DWR
Location: State-wide, but primarily Central Valley
Definition: Multi-faceted program to improve public safety through integrated flood management.
Timeline: Complete foundational objectives by 2025

Yuba Basin Project

Lead Agency: USACE, DWR and YCWA
Location: Yuba, Feather, Bear rivers Watershed
Goal: Increase flood protection for communities of Linda, Olivehurst, Arboga, Marysville, and unincorporated areas of Yuba County
Phase (Timeline): GRR (2010)

Three Rivers Levee Improvement Authority Projects

Lead Agency: Three Rivers Levee Improvement Authority
Location: Southern Yuba County
Goal: Increase flood protection for communities in southern Yuba County
Phase (Timeline): Construction of 200-year protection by 2010

American River Common Features Project

Lead Agency: USACE, DWR, and SAFCA
Location: Sacramento metropolitan area
Goal: Reduce flood risks for the City of Sacramento
Phase (Timeline): GRR (2010)

Sacramento River Bank Protection Project

Lead Agency: USACE and DWR
Location: SRFCP
Goals: Federal program to correct levee erosion issues
Phase (Timeline): Ongoing Phase II EIS (2011)

PL 84-99 Rehabilitation Assistance of Flood Control Works

Lead Agency: USACE and DWR
Location: Central Valley and Sacramento-San Joaquin Delta
Goals: Federal program to provide emergency levee repairs
Timeline: Ongoing

Levee Collaborative

Lead Agency: USACE and DWR
Location: Central Valley
Goals: Develop short- and long-term plans to achieve system-wide compliance with Corps standards for the State Flood System in the Central Valley
Timeline: Ongoing

ACRONYMS

WSAFCA - West Sacramento Area Flood Control Agency
USACE - U.S. Army Corps of Engineers
SBFCA - Sutter-Butte Flood Control Agency
DWR - Department of Water Resources
SAFCA - Sacramento Area Flood Control Agency

Figure 1-8
Port North Levee

1.2.1.5 Port South Levee

This reach encompasses the combination of levees and high ground that exists along the left bank of the barge canal and DWSC from the Sacramento River westward until it meets the DWSC East Levee on the left bank of the DWSC (Figure 1-9).

1.2.1.6 South Cross Levee

This reach extends for approximately 1.2 miles from the intersection of Jefferson Boulevard and the levee along the left bank of the DWSC to the Sacramento River where it intersects the southern limit of Sacramento River South Levee reach. This levee is the southernmost boundary of the city (Figure 1-10).

1.2.1.7 DWSC East Levee

This reach extends along the left bank of the DWSC channel for approximately 2.8 miles in a southerly direction from the high ground making up the western limit of the Port South Levee reach to the intersection of Jefferson Boulevard with the South Cross Levee (Figure 1-11).

1.2.1.8 DWSC West Levee

This reach extends along the left bank of the Yolo Bypass and the right bank of the DWSC approximately 22 miles in a southerly direction from its intersection with the western limit of the Port North Levee to Miners Slough (Figure 1-12).

1.2.1.9 Yolo Bypass Levee

This reach extends in a southerly direction along the left bank of the Yolo Bypass approximately 3.8 miles from its intersection with the left bank levee of the Sacramento Bypass to its intersection with the DWSC West Levee (Figure 1-13).

1.3 Levee Problems and Flood Management Deficiencies

1.3.1 Overview of Levee Failure Mechanisms and Deficiencies

The City engaged a consultant engineering team, led by HDR, Inc., to prepare a problem identification report to determine the type, location, and severity of deficiencies in the WSAFCA flood management system. A draft report was completed in April 2008. In simple terms, floods typically occur from levee failure mechanisms and deficiencies such as when:

- water overtops a levee (inadequate levee height);
- water moves through the levee structure (through-seepage);
- water moves under the levee structure (under-seepage);
- levee slopes are overly steepened or levees have inadequate substance to resist floodwaters or other forces (slope stability and geometry);

- water carries soil away from the levee slope (erosion); and
- vegetation and other encroachments, such as structures, impede levee operations and maintenance (non-compliant vegetation and levee encroachments).

These failure mechanisms and deficiencies are more fully described below, followed by a table of the deficiencies by reach (Table 1-3). Figure 1-14 illustrates the typical deficiencies.

Note: Additional information on the deficiencies can be found in a problem identification report (PIR) (HDR, Inc. 2008) and an alternatives analysis (HDR, Inc. 2009).The deficiencies and alternatives have been refined and focused through progressive stages in the planning process to form the basis of WSLIP's purpose, need, objectives, and proposed activities that are the foundation of this EIS/EIR; and, therefore, may differ slightly among these documents.

Table 1-3. Summary of Levee Deficiencies by Reach

Study Reach	Inadequate Levee Height	Through-Seepage	Under-Seepage	Slope Stability and Geometry	Erosion	Non-Compliant Vegetation
Sacramento River North Levee	✓	✓	✓	✓	✓	✓
Sacramento River South Levee	✓		✓	✓	✓	✓
Port North Levee	✓			✓		✓
Port South Levee	✓		✓	✓		✓

DWSC East Levee		✓	✓	✓	✓	
DWSC West Levee	✓	✓	✓		✓	✓
Yolo Bypass Levee	✓	✓	✓	✓	✓	✓
Sacramento Bypass Levee		✓	✓	✓		

1.3.2 Inadequate Levee Height

Flood management systems are designed to a target level of protection. Determining appropriate levee height is a complex evaluation based on many hydrologic and hydraulic factors, including estimation of the water surface elevation plus a factor of safety above that elevation (also known as freeboard). Another consideration in determining adequate levee height is the contextual relationship of a given levee within the overall flood protection system (i.e., one levee or set of levees cannot be raised to a height such that flows would be directed to flood adjacent or downstream areas). Overtopping is not considered a failure if the event (i.e., target level of protection) to which the levee was designed is exceeded, provided it was constructed and maintained to that design event.

1.3.3 Through-Seepage

Through-seepage occurs when water moves outward from the river channel through the levee cross section (Figure 1-15). The key problem associated with through-seepage is levee breach or collapse, which occurs when the earthen material within the levee is transported by the pressure of the seeping water. Soil piping can occur as the result of seepage. Soil piping is when a hole in a levee becomes exploited by moving water (which naturally seeks the path of least resistance), causing the

Figure 1-13
Yolo Bypass Levee

Typical Levee Deficiencies

- Unstable Slopes - irregular or overly steep slopes compromise the levee structure
- Inadequate levee height - levee height may be too low relative to predicted water levels
- Non-Compliant Vegetation - this can hinder levee monitoring and maintenance, and raise water surface elevation
- Erosion - water flow, wakes, and waves damage the levee by removing soil
- Through-and underseepage

00875.07 EIS\EIR (10-09)

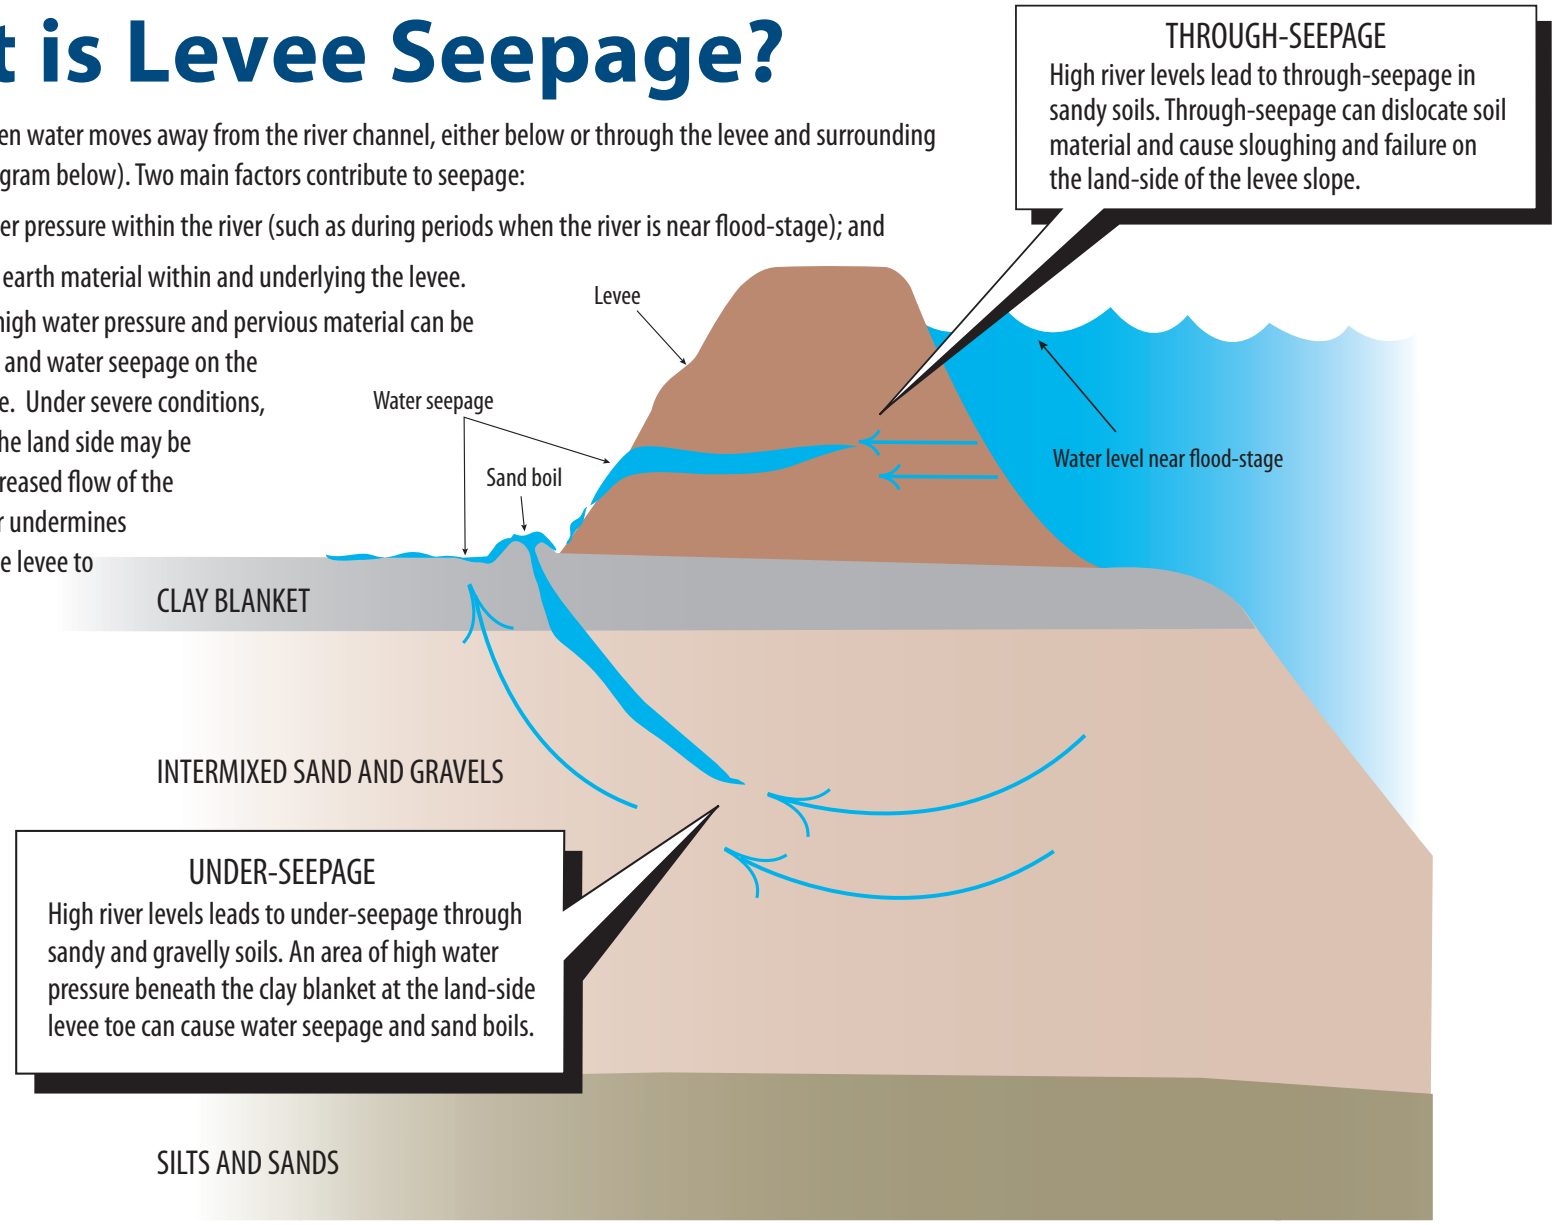

Figure 1-14
Typical Levee Deficiencies

What is Levee Seepage?

Levee seepage is when water moves away from the river channel, either below or through the levee and surrounding land surface (see diagram below). Two main factors contribute to seepage:

- high water pressure within the river (such as during periods when the river is near flood-stage); and
- pervious earth material within and underlying the levee.

The combination of high water pressure and pervious material can be evident in sand boils and water seepage on the land-side of the levee. Under severe conditions, the clay blanket on the land side may be ruptured and the increased flow of the under-seeping water undermines the levee, causing the levee to breach or collapse.

00875.07 EIS\EIR (7-09)

Figure 1-15
Through/Under Seepage

hole to increase rapidly and threaten the levee integrity. Several factors contribute to seepage, including high water pressure (such as during periods of high water in the river or bypass), and pervious earth material (i.e., sandy soils) within or underlying the levee.

1.3.4 Under-Seepage

Similar to through-seepage, under-seepage occurs when water moves outward and downward from the river channel below the levee and surrounding land surface (Figure 1-15). The key problem with under-seepage is when the earth particles which comprise the levee foundation are transported from underneath the levee due to the pressure of the seeping water. This undermining of the levee may result in levee instability or collapse. As with through-seepage, soil piping may occur and cause the levee to breach or collapse, and overall threatens levee integrity. Evidence of under-seepage can often be seen as boils on the land surface on the landward side of the levee. The factors that contribute to under-seepage are the same as those discussed above in through-seepage.

1.3.5 Slope Stability and Geometry

Slope stability is a desirable quality and refers to the resistance of the levee slope to change (landside or waterside). A slope that has an unfavorable horizontal to vertical ratio can be unstable and vulnerable to slipping or sloughing, exacerbated by high flood water elevations. Generally, the approach to determining slope stability can be divided into two categories: steady state and rapid drawdown. Steady state assumes that the flood stage water surface is present for a significant duration, and the presence of water in the levee and the weakening of the levee interior due to through-seepage can cause the landside slope of the levee to slip and wash away. Rapid drawdown also assumes that the flood-stage water surface is present for a significant amount of time, and then is removed quickly as if the river were drained. The water remaining within the levee section weakens the integrity of the levee and when the water surface drops, the waterside slope is vulnerable to slipping and washing away.

Geometry refers to the angle of the slope on both the waterside and landside of the levee as well as the width of levee crown. The USACE guidance regarding geometry has a standard of 3 horizontal feet to 1 vertical foot (or 3H:1V) on the waterside and landside slopes, and a 20-foot-minimum width of levee crown. Levees were evaluated according to USACE's standard for geometry, and those levees that do not meet that standard are considered to be deficient.

1.3.6 Erosion

Erosion is the loss of levee material typically from the force of flowing water, which may be exacerbated by high water velocities, waves, wind action, and boat wake. The high variability in levee soil material, water surface elevation, flow velocities, and ship and boat traffic in local water courses results in commensurate variation in the point at which the levee is at risk (e.g., at lower flows, the levee toe is at risk to erosion; at high flows, the levee face may be at risk).

1.3.7 Non-Compliant Vegetation and Levee Encroachments

Federal project levees, like most of the system protecting West Sacramento, are subject to USACE standards for operations and maintenance. These standards are outlined in general policies and technical publications that universally apply to all Federal project levees and in project-specific

operations and maintenance (O&M) manuals. Recent general guidance from USACE provides greater specificity for the location, type, and degree of vegetation and other encroachments allowable on levees. Under certain circumstances, vegetation and encroachments can exacerbate local erosion, limit the ability to observe levee performance, impair O&M practices, and otherwise affect levee integrity. WSAFCA has established compliance with USACE levee vegetation policies as a goal, and it is understood that projects must comply with USACE levee vegetation policies for Section 408 approval.

1.4 WSLIP Purpose and Need

1.4.1 Purpose, Approach, and Objectives

The purpose of the WSLIP is to achieve a minimum of 200-year flood protection for the entire city by improving the approximately 50 miles of levees protecting West Sacramento. A 200-year flood is a flood that has a 0.5% chance of occurring in any given year, or annual exceedance probability (AEP).

Note: References in this document to level of flood protection (100-year or 200-year) are based on WSAFCA's deterministic approach (the current Federal Emergency Management Agency [FEMA] method). The USACE probabilistic approach is utilized to define system performance for the Section 408 analysis decision. Under either method, the purpose of the project is to substantially reduce the level of flood risk to WSAFCA's service area.

Additional information about defining and understanding flood risk can be found at the official website of the National Flood Insurance Program (NFIP) at: www.floodsmart.gov.

The approach to meet this purpose is to provide a comprehensive evaluation of the entire levee system that protects the city, develop recommended strategies for improvement, and provide a basis for partnerships with Federal and state agencies to implement improvements that meet the flood protection and compatible recreation and open space goals. The objectives under this purpose and approach are to:

- construct levee improvements as soon as possible to reduce flood risk as quickly as possible;
- construct improvements that are politically, socially, economically, and environmentally acceptable;
- provide recreation and open space elements for the city that are compatible with flood improvement actions; and
- ensure continuing Federal assistance for levee repairs and maintenance.

1.4.2 Need for Action

Five needs have been identified for the WSLIP.

- Study results from the comprehensive levee evaluation have shown that the levees protecting the city need improvements to reduce the current level of risk to human health and safety, property, and the adverse economic effect that serious flooding would cause.
- Study results further have shown that the levees in WSAFCA's area are deficient when compared against current Federal standards. Action is needed to bring them up to current

standards in order to maintain eligibility for Federal emergency management assistance. Improvements are necessary to meet the Federal Emergency Management Agency's (FEMA's) minimum acceptable level of flood protection (commonly referred to as the 100-year flood) as specified by the National Flood Insurance Program (NFIP). (HDR, Inc. 2008.)

FEMA's flood risk maps are currently being revised nationwide under a program called RiskMAP (mapping, assessment, and planning). Draft revised FEMA maps show that all or parts of West Sacramento may not meet 100-year flood standards. The WSLIP is intended to incrementally reduce risk to meet or exceed the FEMA standards.

- As required by Senate Bill (SB) 5 (signed by Governor Schwarzenegger in October 2007), the Central Valley Flood Protection Board (CVFPB) must adopt a Central Valley Flood Protection Plan (CVFPP) by July 1, 2012. The CVFPP will require a 200-year level of flood protection for urban areas by the year 2025. Levee improvements are necessary to meet that requirement.
- As a growing community, the City has recreation and open space needs and goals that are unmet. Surrounding waterways represent not only an element of flood risk but also great opportunity for water-based recreation and public open space. Flood protection improvement elements typically underlie or are adjacent to proposed recreation elements that are part of the City's planning documents. There is a need to provide West Sacramento residents with recreation elements that are compatible with flood protection improvements.
- As described in Section 1.2, WSAFCA's area is the downstream-most metropolitan area in the SRFCP. As other projects have been implemented or improvements are being planned to reduce risk and increase flood protection for upstream communities, there is concern that the performance of the SRFCP needs to be evaluated comprehensively to ensure that the individual projects are kept in balance, that effects among the projects are being evaluated, and that risk is not being transferred between communities. The WSLIP represents an important subarea of the SRFCP and merits such study, heightened by West Sacramento's downstream location.

As discussed previously, in light of the flood risk to West Sacramento, WSAFCA is taking proactive measures to reduce risk and improve the level of flood protection for the city. Specifically, the WSLIP and the EIPs under the program are targeted to reduce risk and are proposed in sponsorship by WSAFCA in advance of USACE's project being studied under the West Sacramento GRR. In combination, the WSLIP and actions under the GRR will address the deficiencies and needs discussed above.

To further demonstrate the need for action, details about West Sacramento's flood risk and the consequences of levee failure in West Sacramento are described in the Alternatives chapter (2.4.2.2, Consequences of Levee Failure). Some of the key infrastructure and facilities in West Sacramento that are at risk for flooding are listed in Table 1-4.

Table 1-4. Key Infrastructure and Facilities in West Sacramento

Linear Transportation Facilities	
Interstate 80	Union Pacific Railroad
Highway 50	Sierra Pacific Railroad
Water Supply and Treatment Facilities	
Water Treatment Plant	In-Line Booster Pump Station

Clark Pacific	Netflix
KOVR Channel 13/Channel 31	Flowmaster
Tony's Fine Foods	Nor-Cal Beverage
Sports and Entertainment Facility (and disaster recovery center)	
Raley Field	

1.5 WSLIP Background

The following background provides additional context for the objectives of, purpose of, and need for the WSLIP.

Beginning in 1989, several studies have been conducted by USACE, DWR, and WSAFCA to evaluate the condition of the various levees protecting the city. These studies have indicated that the levee system is deficient and that the consequences of levee failure from a major flood event would be significant. Chapter 2 provides a more detailed explanation of levee deficiencies in the WSLIP area.

Prompted by the studies, WSAFCA in cooperation with other agencies has undertaken several levee repair projects beginning in the early 1990s to quickly and incrementally address urgent levee deficiencies that pose serious flood risk. Detail on these projects is provided below under Local Flood Management History. Many of these repair projects were the result of deficiencies discovered during routine operations and maintenance inspections or during high-water events and repairs were performed on a case-by-case basis.

As a result of knowledge gained from its regional Comprehensive Study (the Sacramento–San Joaquin Rivers Comprehensive Study, also known as the Comp Study) initiated after the 1997 flood, USACE revised its levee criteria regarding through-seepage and under-seepage, problems known to exist within the WSAFCA levee system (U.S. Army Corps of Engineers and The Reclamation Board for the State of California 2002). As part of FEMA's map modernization program, levees must be reevaluated and re-certified using the revised criteria.

WSAFCA's levees have been evaluated according to these latest USACE criteria for stability, seepage, erosion, geometry, and levee height. Data collected from the evaluation show that much of the existing system does not provide protection from the 100-year flood event (the event having a 1% chance of occurring in any given year), the commonly accepted minimum level of flood protection. In addition, an emergency preparedness mapping study analyzed two hypothetical levee failures and determined the rate and depth at which water would flood the city if a levee failure occurred in the studied reaches. This study predicted flooding depths that could exceed 10 feet associated with the 100-year flood event. (HDR, Inc 2008, 2009.)

In July 2006, the City, as part of WSAFCA, decided to take a proactive rather than reactive stance with respect to flood protection. At that time, FEMA was beginning the implementation of a Flood Insurance Rate Map (FIRM) modernization program that could lead to the city being mapped within the 100-year floodplain. This would make flood insurance mandatory for all federally guaranteed loans and restrict development that was expected to bear much of the cost of levee improvements. The city and WSAFCA concluded that it was necessary to perform a comprehensive evaluation of all of the levees protecting the city to determine more definitely its current level of flood protection, determine the magnitude and severity of any deficiencies, and develop recommended strategies for improvement.

In addition to these findings above, several other factors prompted WSAFCA and the City to embark on the WSLIP.

- The CVFPP will require 200-year flood protection for urban areas by the year 2025. The time and effort required to fully evaluate approximately 50 miles of levees, develop recommended strategies for improvement, and implement those improvements prompted action without further delay. In addition, in its General Plan, the City adopted a goal of achieving 200-year flood protection. (City of West Sacramento 2004.)
- The Federal authorization and appropriation process to approve funding and begin evaluation can be lengthy. USACE is in the initial phases of developing the West Sacramento GRR, more fully described later in this chapter (U.S. Army Corps of Engineers and Central Valley Flood Protection Board 2009). In light of these circumstances, WSAFCA launched the WSLIP in a parallel process with identifying smaller-scale improvements that may be candidates for EIPs to address urgent needs and can be planned and designed in advance of or at the same time with the overall program. See description of Central Valley Flood Protection Act below for further description of EIPs.
- In May 2007, WSAFCA sought a new annual parcel assessment from property owners to raise local funds for levee improvements and repairs. The majority of funding to improve the levees will be obtained through state and Federal assistance; however, local communities are required to pay for a portion of the overall costs. The property owners of the city recognized the flood risks and indicated their willingness to participate in improvements by voting to approve an annual parcel assessment in 2007. This funding source facilitated WSAFCA's advancement of the WSLIP.

1.5.1 Regional Flood Management History

The SRFCP was authorized by Congress in 1917. The SRFCP was the major project for flood control on the Sacramento River and its tributaries (Figure 1-1). It was sponsored locally by The Reclamation Board of the State of California (Reclamation Board, reauthorized in 2007 as the Central Valley Flood Protection Board [CVFPB]) and was the first Federal flood control project constructed outside the Mississippi River Valley. Currently, there are several major flood risk reduction projects being planned or implemented within the SRFCP area (Figure 1-3). Projects relevant to the WSLIP are discussed in further detail under Section 1.6, Related Actions, Programs, and Planning Efforts, below.

Prior to European settlement in the mid-19th century, the floodplain of the Sacramento River in the 150 miles between the city of Redding and the Delta varied from 2 to 30 miles wide and annually covered more than 1 million acres. Low, discontinuous levees were built by individual landowners

from the 1840s to the 1890s. Those levees concentrated floodflows and contributed to problems that were worsened by upstream hydraulic mining in the Sierra Nevada foothills in the late 1800s. With the authorization of the SRFCP, USACE and the State of California began managing the project as a "regional system," constructing improvements to approximately 1,100 miles of levees and creating bypasses and floodways.

Although the flood control structures have been extensively improved and upgraded since construction, the underlying foundation of most of the levees and channels pre-dates any state or USACE involvement and still retains the original materials that include dredged riverbed sands, soil, and organic matter. At the time of the SRFCP authorization in 1917, the areas being protected by the levees were primarily agricultural with minimal improved infrastructure such as railroads and highways. Many of these areas are now heavily urbanized and densely populated, including the city of West Sacramento.

The Federal government maintains oversight but has no ownership of or maintenance responsibilities for the Federal levee system, except for few select features that continue to be owned and operated by USACE. Considering these exceptions, the great majority of levees, channels, and related flood control structures are owned, operated, and maintained by local levee and reclamation districts (at the county and sub-county level) and the State of California. Most of the levee and reclamation districts existed prior to the SRFCP authorization in 1917 and have been carrying out maintenance responsibilities. Today, however, most of the levee districts are substantially underfunded and unable to maintain the system to meet current Federal standards. The Federal government can participate in improvements to the Federal levee system in partnership with a local sponsor (the state and/or levee and reclamation districts). The levees surrounding the city are maintained by RDs 537 and 900 and DWR's Maintenance Area 4.

In recent decades, a number of evaluations of levee conditions, as well as repair and reconstruction efforts, have occurred. Some have been in specific response to damage resulting from particular flood events; others have been in response to general levee deterioration over time and deferred maintenance.

In 1986, 1995, and 1997, there were record flood stages in the Sacramento region. As a result, USACE evaluated the level of flood protection in the study area with updated hydrology and levee analysis. It was determined that the risk of flooding from the Sacramento River and its tributaries ranges from 1 in 25 (25-year) to more than 1 in 100 (100-year) each year (or 4% to 1% probability), depending on the location.

1.5.2 Local Flood Management History, Programs, and Activities

Consistent with much of the Sacramento Valley as described above, the levees protecting West Sacramento were initially constructed in the 1840s to 1890s. They later became part of the SRFCP authorized by Congress in 1917. These levees have been strengthened and maintained through several subsequent projects in partnership between USACE, the State of California, the City, and the agencies that maintain the levees.

As a result of the problems experienced during the 1986 flood, USACE initiated a system-wide evaluation of the levees comprising the SRFCP. Due to the large scale of the evaluation, the review was split into five phases. The first phase of this evaluation included West Sacramento and was

documented through an initial appraisal report entitled *Sacramento Urban Area Levee Reconstruction Project, California* (May 1988). This phase included the review of approximately 110 miles of levee and recommended the repair of 34 miles. (U.S. Army Corps of Engineers and Central Valley Flood Protection Board 2009.)

The Sacramento Urban Area Levee Reconstruction Project Basis of Design (November 1989) recommended the repair of two reaches of levee protecting the city of West Sacramento. The first repair reach included two relatively small sites along the right bank of the Sacramento River (in the north part of West Sacramento). The second, and more significant, repair reach included approximately six miles of levee along the right bank of the Sacramento River extending from near the barge canal entrance downstream to the southern city limit. Construction began in November 1990 for the installation of berms to improve stability and manage seepage along both reaches. (U.S. Army Corps of Engineers and Central Valley Flood Protection Board 2009.)

The 1986 flood exposed structural problems and inability of the existing levees to provide critical flood protection to the urban area comprised of the Cities of Sacramento and West Sacramento. As a result, USACE, in cooperation with the State of California, initiated the study documented as the *Sacramento Metropolitan Area, California, Feasibility Report* (also known as the West Sacramento Project). This report was published in February 1992, and indicated the existing flood control system in the study area provided significantly less than a 100-year level of protection. The study went on to recommend a program of improvements which at the time were estimated to provide the city with a 400-year level of protection assuming implementation of a 200-year flood control dam on the American River; however, the recommended plan would provide at least a 150-year level of protection if this American River project element was not implemented. The repairs recommended by the study were authorized in the Water Resources Development Act (WRDA) of 1992 (Public Law [PL] 102-580); however, the 200-year flood control dam on the American River was never authorized by Congress. (U.S. Army Corps of Engineers and Central Valley Flood Protection Board 2009.)

Recent milestones in the flood management context of West Sacramento include the following activities.

- As described above, in 1992, USACE concluded that the levees along the Sacramento River and Yolo Bypass did not provide protection from a 100-year flood event.
- As described above, in 1993, a flood control project was completed as part of the Sacramento Urban Area Levee Reconstruction Project. This project placed a stability berm and related features to address through-seepage along the entire length of the Sacramento River levee bordering the Southport area (referred to in the WSLIP study area as the Sacramento River South Levee).
- In 1994, the City and reclamation districts formed a Joint Powers Authority, WSAFCA, to coordinate, fund, and construct major flood protection improvements that were beyond the means of the individual entities (City of West Sacramento 2000).
- In 1995, WSAFCA formed an assessment district to fund the local cost share for the West Sacramento Project. This project was part of the Federal Sacramento Metropolitan Area Project authorized by the WRDA of 1996, as described above. The WSAFCA assessment funded geotechnical and engineering investigations of the Sacramento River levees and the southern boundary cross levee in the Southport area (PB 2007). The West Sacramento Project was designed to provide the city with a greater than 200-year level of protection.

- During the 1997 record flood stage event, the levees surrounding the city sustained minor damage. As design work was nearing completion on the West Sacramento Project, under-seepage was noted along the Sacramento Bypass levee.
- In 1998, stability issues became apparent along a levee maintained by RD 537 just north of the Southern Pacific Railroad tracks.
- In 2002, the West Sacramento Project was substantially completed. This project involved raising more than 1 mile of the south levee of the Sacramento Bypass by up to 5 feet and raising 4.5 miles of the Yolo Bypass levee by up to 5.5 feet.
- In 2008, WSAFCA completed an EIP known as the I Street Bridge EIP. This EIP improved a critical section of levee in the redevelopment area along the riverfront of the city to reduce flood risk to public safety, private property, and public infrastructure. The EIP improved a 475-linear-foot reach of the Sacramento River North Levee of the WSLIP study area to address the problems of through- and under-seepage. This EIP and Section 408 action was expeditiously completed by WSAFCA, the State of California, and USACE.

In addition to these activities, the City has enacted other policies and practices that are part of WSAFCA's overall flood management program to address flood risk, some of which are outlined below.

- The City has in place an Emergency Operations Plan, which addresses flood safety through a Flood Plan and Evacuation Plan. To ensure adequacy, conformance with state-of-the-art standards, and to account for growth, the Emergency Operations Plan is reviewed annually and a comprehensive update is conducted every 3 years or more frequently as needed. Based on this review and revision cycle, the Emergency Operations Plan addresses residual flood risk as flood improvements are implemented and as the population and built environment change within WSAFCA's planning area.
- As described previously, in May 2007, property owners in West Sacramento approved a new annual parcel assessment to provide funding for flood improvements, facilitating the WSLIP study.
- Also as of 2007, the City's municipal code (Chapter 15.50) requires new developments to provide 200-year protection or pay into an in-lieu fee program to fund WSAFCA's flood protection efforts.

1.5.3 Local Recreation Needs

The City, as a member agency of WSAFCA, is proposing recreation elements that are compatible with flood improvements to meet recreation needs. For example, the Sacramento River is central to the identity and image of the city, yet opportunities to enjoy it are hampered by lack of safe and accessible public access points. The city is also lacking developed facilities and infrastructure for dedicated off-street bikeways, environmental interpretation and education, fishing, boating, hiking, and other active and passive outdoor recreation experiences. This situation has been heightened by the recent growth of the local population, demographically influenced by young families and individuals oriented toward outdoor recreation.

The *City of West Sacramento Parks Master Plan* (Parks Master Plan) from 2003 identified several key recreation opportunities for the city that will enable its citizens and visitors to enjoy the resources provided by the Sacramento River and other waterways. Some of those opportunities include

utilizing corridors along the Sacramento River, DWSC, turning basin, barge canal, and Yolo and Sacramento Bypasses. These corridors are an opportunity to develop pedestrian and non-motorized linkages that can be used for transportation as well as recreation (SmithGroup JJR 2003).

As part of its Parks Master Plan, the City performed a demand analysis to determine the community's need for certain services. Twelve demands were noted, two of which relate to the City's waterway corridors, summarized below.

- **Improved water access.** Residents value the water resources available in West Sacramento. They desire improved access to water-related recreation such as fishing, boating, swimming, and passive use (e.g., wildlife viewing and hiking).
- **Recreation corridors and trails.** The residents support corridors for bicycling, walking, and horseback riding.

Further substantiating the need for bicycle and pedestrian paths, the 1991 *West Sacramento Bicycle and Pedestrian Path Master Plan* (Callander Associates 1991) and Addendum (City of West Sacramento Parks and Community Services Department 1995) identified opportunities, constraints, and design standards for a citywide network of bicycle and pedestrian paths. The plan also described the City's understanding of these paths as more than a recreational resource; they also encourage bicycling and walking as alternatives to automobile transportation. The Parks Master Plan demand analysis found that the residents support construction of these corridors for bicycling, walking, and horseback riding.

Supported by the demand analysis, the City has established the following goals and objectives.

- Acquire and develop recreation corridors located along watercourses and railroad rights-of-way to link the park system and provide additional recreation opportunities.
- Locate new parks to take advantage of the city's natural resources, including the river and other watercourses.
- Provide improved river access for boating and fishing.
- Develop open space areas to protect significant wetlands and riparian forests, and to provide passive recreation opportunities.
- Facilitate bicycle and pedestrian travel as an alternative to automobile use.

1.6 Related Actions, Programs, and Planning Efforts

This section provides an overview of other flood management activities that comprise the regional planning context for the WSLIP.

1.6.1.1.1 Sacramento Metropolitan Area, California, Feasibility Report (West Sacramento Project)

As introduced earlier in this chapter, the *Sacramento Metropolitan Area, California, Feasibility Report* (also known as the West Sacramento Project) was completed in 1992 and describes the results of studies of flood problems along the Sacramento River and Yolo Bypass from the Sacramento Weir downstream to an area just south of Freeport. The West Sacramento Project included plans for improving flood protection for the city of West Sacramento. The study area is located along the right

bank of the Sacramento River in Yolo County, California. The West Sacramento Project was substantially completed in 2002. The project involved raising more than 1 mile of the south levee of the Sacramento Bypass by up to 5 feet and raising 4.5 miles of the Yolo Bypass levee by up to 5.5 feet. Two deficient sites remain under this project and are scheduled for completion by 2010.

1.6.1.1.2 West Sacramento General Re-Evaluation Report

The original West Sacramento Project of 1992, described above, studied only a small portion of the levees that provide flood protection for the city of West Sacramento. As introduced earlier in this chapter, presently, the USACE and WSAFCA are developing a GRR for West Sacramento levee improvements to assess the entirety of the levees protecting the city of West Sacramento in light of most recent criteria and knowledge regarding levee design.

USACE uses GRRs to present the results of a reevaluation of a previously completed study, using current planning criteria and policies, due to changed conditions and/or assumptions. The results may reaffirm the previous plan, reformulate and modify it, or find that no plan is currently justified. The results are documented in a GRR which, if recommended and supported, also serves as the decision document for a Federal action (U.S. Army Corps of Engineers and Central Valley Flood Protection Board 2009). NEPA analysis for the GRR will be separate from that for the WSLIP, but the processes being closely coordinated for consistency and efficiency.

The primary objective of the West Sacramento GRR is to determine the extent of Federal interest in additionally reducing the flood risk within the study area while concurrently exploring opportunities to increase recreation and restore the ecosystem along the Sacramento River within the study area. USACE anticipates completion of the GRR in 2012.

In regard to the relationship between the WSLIP and the West Sacramento GRR, the WSLIP study area and the GRR study area overlap and the improvements considered may as well. Some improvements evaluated in this EIS/EIR (specifically the EIPs), which would be implemented by WSAFCA, are scheduled to be initiated prior to the GRR authorization, with the expectation that the flood protection improvements that are constructed in advance of any Congressional action on the GRR will be found to be consistent with the recommendations contained in the GRR. On that basis, WSAFCA anticipates that the non-Federal costs incurred in implementation of the WSLIP improvements could be credited against the remaining non-Federal share of the cost of the project studied under the GRR. More specifically, requests for general credit for flood control under Section 104 of the WRDA of 1986 would allow the work conducted by WSAFCA and described in the GRR to be partially credited against the local cost sharing requirements of the West Sacramento Project GRR as long as the project features constructed are compatible with the USACE project. Because implementation of the improvements by WSAFCA does not immediately use Federal funds, it would not result in a commitment of Federal resources that would prejudice selection of a GRR alternative before a final decision on the GRR alternatives is made. In addition, the project-specific improvements considered in this EIS/EIR (the EIPs) are limited to a small portion of the overall flood protection system considered in the GRR. In summary, the WSLIP is being advanced by WSAFCA to facilitate EIPs and a program evaluation that are intended to be consistent and compatible with the ultimate West Sacramento Project GRR.

1.6.1.1.3 Sacramento River Deep Water Ship Channel Project

The Sacramento River Deep Water Ship Channel Project was originally authorized by Congress and implemented by USACE in 1986. The project involved deepening the existing 46.5-mile DWSC from

30 feet to 35 feet and widening portions of the channel to improve navigational efficiency for movement of goods and safety. Construction was initiated in 1989, but work was suspended in 1990 because of a lack of local share funds to match Federal funds and issues related to unresolved infrastructure relocation. A portion of the channel was deepened to the authorized depth of 35 feet. In 2008, USACE, in coordination with the Port of West Sacramento, started the process of conducting a Limited Reevaluation Study and preparing a joint Supplemental Environmental Impact Statement and Subsequent Environmental Impact Report (SEIS/SEIR) to evaluate the action of resuming construction of navigational improvements to the DWSC. USACE anticipates releasing a draft study and SEIS/SEIR to the public in mid-2010. Construction is anticipated to start mid-2011 and be completed in fall 2013. The project is estimated to produce 6.4 million cubic yards of dredged material. The study and SEIS/SEIR will evaluate the feasibility and beneficial use of providing dredged material to local projects.

1.6.1.1.4 Sacramento Weir Sediment Removal Project

DWR removed approximately 38,600 cubic yards of accumulated sediment from the Sacramento Weir approach to restore its flow capacity (ongoing at the time of writing this EIS/EIR). The average depth of sediment removed is 4 feet with depths ranging from 2 to 5 feet along the length of the weir. After the sediment was removed, the invert elevation directly in front of the weir matches the weir apron elevation of 21.27 feet. The area of cut has an average width of 160 feet from the weir apron to the hinge point of the river bank and a length of approximately 2,100 feet (approximately 7.75 acres). The total area of disturbed ground, including in-channel and overbank haul paths and disposal area, is about 19.2 acres. The excavated sediment was placed along the landslide of the south levee of the Sacramento Bypass. The sediment was placed as fill on the existing stability berm on the levee toe. The sediment raised the existing stability berm approximately 6.3 feet for a 1-mile stretch.

1.6.1.1.5 Central Valley Flood Protection Act

The Central Valley Flood Protection Act, enacted in California in 2005, calls for the DWR to develop a CVFPP by January 1, 2012. The CVFPP will outline a comprehensive system-wide approach for the protection of lands currently protected from flooding by the SRFCP and the corresponding San Joaquin River watershed to the south. It also establishes a new standard of 200-year flood protection for urban areas in the Central Valley and requires this standard to be achieved by 2025.

The people of California also passed two bond measures that provide approximately $5 billion toward flood improvements to reduce flood risk, particularly to state-Federal levees protecting urban areas in the Central Valley. These levee improvements are expected to occur over the next 10 years with much of the bond money spent after the year 2012. However, there are urgent needs to improve inadequate flood protection in existing urban areas in advance of the overall comprehensive effort. These advance efforts are termed EIPs. EIPs will be implemented ahead of the comprehensive effort, yet be designed to ensure that they do not eliminate opportunity or prejudice flood risk-management alternatives that would provide regional or system-wide benefits. Local agencies and the state are identifying and planning EIPs in a parallel process to be compatible with comprehensive, system-wide studies.

Along with the requirement for increased flood protection by 2025, one of the objectives of the CVFPP is

increasing the engagement of local agencies willing to participate in flood protection, ensuring a better connection between state flood protection decisions and local land use decisions (Draft Framework for Early Implementation Projects and Section 408 Approval).

In line with that objective, WSAFCA has proposed the WSLIP.

1.6.1.1.6 Natomas Levee Improvements Program

As part of its long-term program to improve the Natomas Basin levee system, the Sacramento Area Flood Control Agency (SAFCA) proposes to continue waterside and landside levee-strengthening efforts, including levee raises, seepage remediation, increased bank protection, levee stabilization, and flattening of landside levee slopes under the Natomas Levee Improvements Program (NLIP), an EIP. These activities were evaluated in the following environmental documents.

- Local Funding Mechanisms for Comprehensive Flood Control Improvements in the Sacramento Area (2007)
- Natomas Levee Improvements Program, Landside Improvements Project (2007)
- Natomas Levee Improvements Program, Bank Protection Project (2007)
- Natomas Levee Improvements Program, Landside Improvements Project- Phase 2 Project (2008)
- Natomas Levee Improvements Program, Landside Phase 3 Levee Improvements Project (2009)
- Natomas Levee Improvements Program, Landside Phase 4a Levee Improvements Project (2009)

Specific elements are described below.

Natomas Levee Improvement Program Landside Improvements Project

SAFCA proposes to provide the Natomas Basin with at least a 100-year level of flood protection by the end of 2010 and ultimately a 200-year level of flood protection. Approximately 26 miles of levees surrounding the Natomas Basin require one or more forms of remediation to address the potential for failure in a 100-year or 200-year flood event. This will require improving conditions along the Natomas Cross Canal South Levee and the Sacramento River East Levee, American River North Levee, Natomas East Main Drain, and the Pleasant Grove Creek Canal. This is a four-phase construction program: Phase 1 occurred in 2008, Phase 2 in 2009, and Phases 3 and 4 are scheduled for 2010.

Natomas Levee Improvement Program Waterside Improvements Project

SAFCA proposes to implement bank protection measures at nine sites along the left bank of the Sacramento River to allow FEMA to certify the levee and to meet SAFCA's 200-year flood protection standard. The project will address erosion and scour, which can threaten levee integrity and ultimately cause levee failure. SAFCA has determined that repair of both moderate and high risk sites is needed to ensure FEMA certification and meet SAFCA standards. Approximately 8,500 linear feet of bankline have been identified for repairs at the nine proposed sites, which are located on the left bank of the Sacramento River between River Mile (RM) 69 (upstream of the confluence with the American River and 2 miles downstream of the Interstate 5 river crossing) and RM 79 (the confluence with the Natomas Cross Canal).

1.6.1.1.7 Sacramento River Flood Control System Evaluation

Following the flood of 1986, USACE and the State of California, along with local partners, completed a comprehensive evaluation of the Sacramento River Flood Control System and initiated a flood risk management program aimed at repairing, raising, and strengthening urban levees, among other activities. This effort, known as the Sacramento River Flood Control System Evaluation (commonly referred to System Evaluation) resulted in the repair of more than 70 miles of deficient levees. However, to date, not all the authorized repairs have been completed. Moreover, the completed repairs were built to less rigorous standards than current standards.

1.6.1.1.8 Sacramento–San Joaquin Rivers Comprehensive Study

Following the 1997 flood, the Sacramento-San Joaquin Comprehensive Study was initiated by the state and USACE to formulate comprehensive plans for flood risk reduction and environmental restoration. This study was unable to stimulate widespread public or political interest in flood risk reduction or environmental restoration activity beyond the ongoing urban levee improvement programs. The study did result in a new set of engineering criteria for the design and evaluation of urban levees and a greatly expanded scope and cost for the ongoing urban levee improvement efforts on the Sacramento and American Rivers. In addition, the adequacy of previous repairs was reviewed.

1.6.1.1.9 American River Common Features Project

To increase flood protection for the city of Sacramento, which is bordered by the left bank of the Sacramento River, the American River Common Features Project (Common Features) was authorized by Congress in the WRDA of 1996. This authorization called for strengthening the north and south levees of the American River and raising and strengthening the upper 12 miles of the left levee of the Sacramento River in the Natomas area, just north of the city of Sacramento. These improvements were considered *common features* of any comprehensive plan of flood protection for the Sacramento area that might ultimately be approved by Congress. In WRDA of 1999, the scope of the Common Features authorization was expanded to include raising portions of the north and south levees of the American River (including the Mayhew Levee), additionally strengthening portions of the north levee of the American River, and raising and strengthening the north and south levees of the Natomas Cross Canal in the Natomas area. In 2006, the Common Features authorization was deemed sufficient to cover improvements to the left levee of the Sacramento River near the Pioneer Reservoir and in the Pocket/Freeport area.

USACE is currently developing two post-authorization change studies. The Common Features GRR is reevaluating the previous Common Features project and identifying levee improvements needed to provide the city of Sacramento and the Natomas area to the north with at least a 200-year level of flood protection. The Natomas Post-Authorization Change Report will document the evaluation of features in the Natomas Basin only. Both are expected to be presented to Congress in 2010.

1.6.1.1.10 Sacramento River Bank Protection Project

USACE is responsible for implementation of the Sacramento River Bank Protection Project (Sac Bank) in conjunction with its non-Federal partner, CVFPB. The SRBPP is a continuing construction project authorized by Section 203 of the Flood Control Act of 1960. The purpose of this project is to provide protection to the existing levee and flood control facilities of the SRFCP. To date, work has been carried out in two phases, with a total of about 820,000 feet of river stabilized under the

project. Phase I consisted of 435,000 feet and Phase II's original authorization included 405,000 feet. Current SRBPP work is being conducted under Phase II of its existing Federal authorization, with approximately 14,000 feet remaining to be constructed in 2009–2010. Projects within the WSAFCA service area are being evaluated under this program.

1.6.1.1.11 Flood Control and Coastal Storm Emergency Act

The Flood Control and Coastal Storm Emergency Act (PL 84-99) authorizes USACE to undertake activities including disaster preparedness, advance measures, emergency operations, rehabilitation of flood control works threatened or destroyed by flood, protection or repair of federally authorized shore protective works threatened or damaged by coastal storms, and provisions of emergency water due to drought or contaminated source. PL 84-99 establishes an emergency fund for emergency response preparations for natural disasters, for flood fighting and rescue operations, and for rehabilitation of flood control and hurricane protection structures. Under PL 84-99, an eligible flood protection system, such as the SRFCP, can be rehabilitated if damaged by a flood event. USACE has the responsibility to coordinate levee repair issues with interested Federal, state, and local agencies following natural disaster events where flood control works are damaged.

The state of California experienced a series of storms affecting federally authorized flood damage reduction projects between December 28, 2006, and January 9, 2007. High water elevations associated with these storms resulted in damage to levees along the Sacramento River and its tributaries. These damages included the development of boils at a site located along the right bank of the Sacramento River in RD 900. This site was located near Davis Road at RM 54.2. USACE, in cooperation with CVFPB, constructed a seepage berm at this site in 2007 under the general authority PL84-99. The 80-foot-wide by 200-foot-long seepage berm, consisting of drain rock encapsulated in geotextile fabric topped with levee fill, was placed at the landside toe of the levee over the area of reported boils.

1.7 Community Outreach, Agency Coordination, and Issues of Known Controversy

1.7.1 Community Outreach

USACE and WSAFCA have established a proactive multi-media outreach program to communicate the WSLIP. The approach to the outreach program has been to go beyond the guidelines and requirements of NEPA and CEQA for public noticing to ensure the affected community and other interested stakeholders are informed, engaged, and involved through an accessible, open, and transparent process. Thus far, the outreach program has included the following actions:

- four scoping meetings for the environmental document (two for the joint NEPA/CEQA document and two prior for CEQA only);
- publication of notices in local newspapers of major circulation;
- publication in the *Federal Register*;
- notification to the State Clearinghouse;
- posting NEPA notices on the USACE website;

- posting CEQA notices and project information on the City/WSAFCA website;
- publication of feature articles in the City Lights newsletter, distributed quarterly to all city residents for updates and information about City business;
- presentation and discussion of the status of the WSLIP at various public meetings for elected boards and commissions;
- direct mailing to residents within proximity of proposed construction activities;
- phone calls to public agencies;
- small-group meetings with interested stakeholders; and
- posting of notices in public places.

As the proposed improvements and EIS/EIR are further developed, the outreach program will continue in a broad sense via the methods listed above and will expand through more targeted specific outreach to residents and businesses who might be more directly affected by construction or operation of the proposed improvements.

To date, the results of the outreach program have been very favorable, constructive, and supportive for the WSLIP. The tone and substance of the input has been consistent with the very favorable response for the voter-approved assessment to fund the local share of the WSLIP. Comments received from the public have been considered to refine the project description and the environmental analysis.

A more detailed accounting of the scoping process is provided in Appendix A.

1.7.2 Agency Consultation and Coordination

1.7.2.1.1 Coordination with other Federal, State, Regional and Local Agencies

The WSLIP has been planned in coordination and cooperation with numerous local, state, and Federal agencies. In Chapter 3, the regulatory setting for each respective resource describes the compliance with applicable Federal, state, regional and local laws and regulations, including consultation to date with various agencies. The following is a summary of those coordination efforts.

Resource Agency Coordination

Over the course of the project planning and environmental review for the WSLIP, WSAFCA and USACE have coordinated informally with the U.S. Fish and Wildlife Service (USFWS), the National Marine Fisheries Service (NMFS), and the California Department of Fish and Game (DFG).

Throughout 2008 and 2009, coordination has consisted of informal agency meetings, site visits, telephone calls and electronic mails to discuss program effects on habitats and potential avoidance and minimization measures. Information was exchanged to apprise each resource agency of the program status and progress, and to request feedback.

Native American Consultation

In January 2008, the Native American Heritage Commission (NAHC) was contacted to request a search of their Sacred Lands File. The NAHC staff responded in January 2008 with a list of Native

American contacts for both Yolo and Solano Counties and the results of the sacred lands data base research that was negative for findings in the program corridor.

ICF Jones & Stokes staff sent letters to the Native American contacts on the lists provided by NAHC. The correspondence included a map depicting the program corridor, a brief description of the proposed program, and a request for the contacts to share any knowledge or concerns they may have regarding cultural resources in or adjacent to the study area. ICF Jones & Stokes received a letter response dated April 2008 from Mr. Marshall McKay, Tribal Chairman for the Rumsey Band of Wintun Indians. Mr. McKay's letter stated his gratitude for the letter notification about the proposed levee alternatives and that he was not aware of any sites of religious or cultural importance in the program corridor. Mr. McKay also stated that the Rumsey Indian Rancheria of Wintun would like to be notified of any cultural finds unearthed during construction actions.

1.7.2.2 CEQA Responsible and Trustee Agencies

This EIS/EIR will be used by Responsible and Trustee Agencies to determine the effects of the proposed action. Responsible Agencies are those that have a legal responsibility to approve the program or project. These agencies are required to rely on the Lead Agency's environmental document in acting on whatever aspect of the program or project requires their approval but must prepare and issue their own findings regarding the program or project (CEQA Guidelines Section 15096). Trustee Agencies are those that have jurisdiction over certain resources held in trust for the people of California but do not have legal authority over approving or carrying out the program or project. Responsible and Trustee Agencies for the WSLIP are presented in Table 1-5.

Table 1-5. Responsible and Trustee Agencies

Agency	Jurisdiction
Trustee Agency	
California Department of Fish and Game	Fish and wildlife Native plants designated as rare or endangered Game refuges Ecological reserves
State Lands Commission	State-owned "sovereign" lands
Responsible Agency	
California Department of Fish and Game	Fish and wildlife Native plants designated as rare or endangered Game refuges Ecological reserves
Office of Historic Preservation	Historic and cultural resources
Central Valley Flood Protection Board	Levee modifications
California Air Resources Board	Air quality
Regional Water Quality Control Board (#5)	Discharges to water bodies
California Department of Water Resources	State water and flood control interests

1.7.3 Issues of Known or Expected Controversy

NEPA requires that project proponents identify issues of known controversy that have been raised in the scoping process and throughout the development of the project. Thus far, no substantial issues have been discovered through public feedback. However, the following potentially controversial issues are anticipated to arise in the conduct of the environmental analysis process.

1.7.3.1 Construction-Related Effects

As the levee system in the program area is in close proximity to residential areas and other developed land uses, flood improvements proposed under the WSLIP and project-level EIPs are likely to result in construction-related effects. These effects include those under the topics of public safety, noise, traffic, and air quality and are specifically described in Chapter 3, Affected Environment and Environmental Effects. A specific discussion about impacts to residents is addressed under Socioeconomics and Community Effects in3.12, 4.14., and 5.14. This issue is of special concern at The Rivers, where residences will experience access inconveniences and disruption of services.

1.7.3.2 Property Take and Restricted Property Access

A specific subset of construction-related effects involves potential conflicts with private property underlying or near proposed improvements. In some cases there may be temporary property take in the form of construction easements to build the project; permanent take for construction, operations, or maintenance of the project; or temporary restrictions on access to private property. These effects are described under the land use section in Chapter 3, Affected Environment and Environmental Effects.

1.7.3.3 Restriction of Vegetation on Levees

USACE recently published technical guidance and reinforcement of policies restricting woody vegetation on Federal project levees. Implementation of such guidance has stirred controversy in the Sacramento region as cursory assessments have shown that much vegetation may require removal, resulting in effects on fish and wildlife habitat and social values like recreation and aesthetics. The WSLIP would be subject to this guidance. This issue is further described in Chapter 2, Alternatives, and under the effects discussions for vegetation, fish, wildlife, visual resources, and recreation.

1.7.3.4 Climate Change and Sea-Level Rise

Global climate change and resultant sea-level rise are phenomena receiving international attention. These issues are further discussed in the effects discussions in Section 3.2, Flood Control and Geomorphic Conditions, and Section3.6, Air Quality and Climate Change.

Chapter 2
Alternatives

2.1 Introduction

This chapter describes the following elements:

- general information about improvements, including the screening process;
- WSLIP program description for flood and recreation improvements;
- project-level description for two EIPs: CHP Academy EIP and The Rivers EIP (in summary); and
- environmental commitments incorporated into the program and project description to be considered in the environmental analysis for all action alternatives.

2.2 General Information about Alternatives

2.2.1 Approach to Alternatives

NEPA and CEQA generally require that an EIS and EIR (respectively) consider a range of alternatives that would attain most of the basic project purpose, need, and objectives while avoiding or substantially lessening project effects. A range of reasonable alternatives is analyzed to sharply define the issues and provide a clear basis for comparison among the options. The NEPA/CEQA analysis also must include an analysis of a no-action or no-project alternative.

Consistent with NEPA standards, alternatives at the program level are analyzed on an equal, non-preferential basis (i.e., there is no proposed project/preferred alternative) and at an equal level of detail. As required under NEPA and CEQA, a no-action (no-project) alternative has been included to allow comparison of impacts of a range of alternatives including no project implementation.

The alternatives for the program have been developed on a reach-by-reach basis, rather than basin-wide. Because each reach has specific levee deficiencies and each levee deficiency has a number of different treatments that could be used to improve the levee, a reach-by-reach approach allows greater flexibility for project development, analysis, and implementation. In keeping with this approach, the alternative levee treatments are not bundled or packaged but rather are evaluated independently at the program level, allowing for flexible combinability at the project level.

Such flexibility in combining treatments is important to account for variable circumstances and to ultimately assist decision-making for determining the most appropriate treatment(s) based on those circumstances. The circumstances are further subject to change due to the fact that the program would be implemented over many years, and in that time localized flood risk may change, new deficiencies may be identified, new design criteria may be implemented, new treatment measures or construction methods may be developed, or land use and environmental conditions may change.

In describing and analyzing the WSLIP at the program level, the individual flood and recreation improvements function as alternatives in accordance with NEPA and CEQA.

In describing and analyzing the EIPs under the WSLIP at the project level, flood and recreation improvements have been packaged into at least two project alternatives in accordance with NEPA and CEQA.

2.2.2 Alternative Screening Process

The alternative screening process includes a pre-program screen, program-level screen, and project-level screen. Potential levee improvements considered for the WSLIP undergo several stages of screening prior to proposal for action. The pre-program stage of screening is fairly coarse, simple, and qualitative whereas the project-level screening stage is more refined, intricate, and quantitative. This process is summarized below. Improvements that were considered at the pre-program screening stage but not studied in further detail, as well as the program improvements carried forward for consideration in this EIS/EIR are described below after the Alternative Screening Process.

2.2.2.1 Pre-Program Screen

Prior to analysis in the EIS/EIR, certain improvements were screened out based on the following criteria.

- **Geography and jurisdictional authority.** Improvements outside of WSAFCA's and its member agencies' boundaries have been screened out because they are beyond the purview and authority of WSAFCA to implement. There may be exceptions for alternatives proposed outside of WSAFCA's boundaries if mitigation were required for project effects or if downstream modifications were needed to improve flood protection for West Sacramento. While this criterion is an important consideration, no alternative was eliminated solely on this basis (i.e., the alternatives raised other concerns that eliminated them from further analysis notwithstanding WSAFCA's jurisdiction).
- **Ability to meet purpose and objectives.** Alternatives that do not substantially meet the WSLIP purpose and objectives have been screened out. Similarly, alternatives that are not targeted at nor have a direct connection to the WSLIP purpose and objectives have been screened out. As presented in Chapter 1, the purpose of the WSLIP is to achieve a minimum 200-year level of flood protection for the entire city by improving the levees protecting West Sacramento. The program objectives are as follows:
    - construct levee improvements as soon as possible to reduce flood risk as quickly as possible;
    - construct improvements that are politically, socially, and environmentally acceptable;
    - provide recreation and open space elements for the city that are compatible with flood improvement actions; and
    - ensure continuing Federal assistance for levee repairs and maintenance.

  Sub-factors for determining ability to meet the purpose and objectives include long-term reliability, avoidance of indirect effects and unintended consequences, and exorbitantly high or unknown costs.

2.2.2.2 Program-Level Screen

Improvements that passed the pre-program screen are evaluated uniformly against a set of criteria and compared to one another and no action at the program level. The environmental analysis in this EIS/EIR is part of the program-level screen, combined with other planning, engineering, and financial factors. Although the final criteria are subject to change as the WSLIP develops and the process unfolds, the criteria are likely to include the following elements:

- ability to address the flood management problem or levee deficiency;
- avoidance, minimization, and mitigation of environmental effects;
- land use compatibility;
- integration of multi-purpose objectives, such as delivery of recreation features that are compatible with flood improvements;
- cost; and
- public feedback, including that discovered during the EIS/EIR process.

2.2.2.3 Project-Level Screen

Beyond the program level, screening criteria are applied to identify reach-specific improvements. As with the program-level screen, improvements are evaluated uniformly against a set of criteria, are compared to one another and no action, and the environmental analysis in this EIS/EIR is part of the project-level screen. The project-level criteria are focused on determining the most appropriate project proposal based on local context and deficiencies. Ultimately, an applicant-preferred alternative (as determined by WSAFCA) is formulated as informed by the screening criteria. While the final criteria are subject to change as the WSLIP develops and the process unfolds, the criteria are likely to include the following elements:

- ability to meet the project objectives (i.e., address the deficiencies) to reduce risk;
- availability of funds;
- scalability of construction;
- real estate requirements;
- land use compatibility;
- permit requirements;
- environmental constraints;
- integration of multi-purpose objectives, such as delivery of recreation features that are compatible with flood improvements;
- evolving technical policy; and
- public feedback, including that discovered during the EIS/EIR process.

These same criteria were applied to select the I Street Bridge EIP completed in 2008 and would be used for prioritizing future projects, including the project-level EIPs analyzed in this EIS/EIR (see Chapters 4 and 5).

2.3 Program-Level Alternatives Considered but Not Carried Forward

Several alternatives to the WSLIP were considered but not carried forward based on the pre-program screening criteria presented in Section 2.2.2.1. These alternatives are briefly described below.

2.3.1 Reoperation of Upstream Reservoirs

Upstream reservoirs are currently operated to meet a number of different objectives, including water supply, flood management, power production, water quality, and fisheries. Reoperation to optimize attenuation of flood flows could potentially reduce flood risk to WSAFCA, but may compromise the ability to meet other mandated management objectives. Given that many agencies and other stakeholders would need to be involved, it is unlikely that an agreement with respect to reoperation would be reached in the near term, if possible at all to achieve any meaningful benefit to WSAFCA. Therefore, this alternative was eliminated from further analysis due to its uncertainty in meeting the purpose and objectives and due to the authority required beyond WSAFCA's geographic and jurisdictional scope.

2.3.2 Reoperation of Weirs

The elevation and operational criteria for the Fremont Weir, Tisdale Weir, Sacramento Weir, and others determine the flow split between the main stems of the rivers versus flows directed into the bypasses of the SRFCP. While reoperation of certain weirs may reduce water surface elevation in the Sacramento River and therefore reduce flood risk from the river to WSAFCA's area from northeast and east, flow would be increased in the Yolo Bypass and Sacramento Bypass, increasing the risk of failure from the northwest and west from the bypasses. The unintended and negative consequences may extend beyond WSAFCA's area and may transfer risk to other populations. Moreover, this action would essentially re-operate the system on a broad scale, which is not in WSAFCA's authority. Therefore, this action was screened out from further consideration.

2.3.3 Development of Additional Upstream Storage

Similar to reoperation of upstream reservoirs, development of increased capacity for flood water storage within the SRFCP upstream of WSAFCA's area (such as through new reservoirs, enlarged bypasses, and setback levees) presents a possibility for reducing flood risk to the city of West Sacramento. However, likewise with reoperation of upstream reservoirs, WSAFCA does not own or control upstream properties for developing additional storage; therefore, this action has been screened out from further consideration. Further, these actions require system-wide evaluation and may result in negative effects and unintended consequences and are not specifically targeted at WSAFCA's purpose and objectives.

2.3.4 Raising Building Pads

This alternative involves raising building pads to an elevation above the floodplain. However, this action would not meet the purpose and objectives for the following reasons:

- it would not be feasible to raise the building pads of existing structures, and therefore would not protect existing development;
- the area of the city planned for development but not yet built out is too vast to uniformly raise the building pads above the floodplain; and
- flood depths in some parts of the city are too great for raising building pads above the floodplain to be feasible on a large scale.

While it may be possible for existing development to be retrofitted to be flood-proofed or to raise all habitable buildings above the 200-year flood level and for new development to be designed and built to this standard, implementation would require substantial cost, time, and re-evaluation of environmental effects and local permitting, review, and approval processes. This alternative would not substantially meet the program objectives in that it would not reduce flood risk in an expedited fashion for the entire population of the city of West Sacramento due to the fact that construction activities would likely be staged over tens of years, leaving parts of the population at greater risk than others. Furthermore, it would not provide flood protection for all property because non-habitable buildings, streets, and parking lots would not be raised above the 200-year flood level. Further complicating this alternative is that potential flood depths in the some parts of the city are too great to feasibly enable the raising of building pads or structural retrofits. For these reasons, this alternative was eliminated from further consideration.

2.3.5 DWSC Closure Structure and Gated Weir

This alternative proposes to construct a flood barrier structure within the Sacramento DWSC and gated overflow weir structure that would prevent flood flows from proceeding north in the ship channel. The gated weir would be constructed along the DWSC West navigation levee and would divert flood flows from the Yolo Bypass into the DWSC. The closure structure would be operated to prevent flood flows from proceeding north and potentially flood the Port of West Sacramento or the city. While this alternative may provide some degree of flood protection for the city, it would not meet the objective of providing a 200-year level of flood protection because portions of the city would remain susceptible to flooding. In addition, operation of the closure structure and the weir may require reoperation of flood control system components (e.g., the Yolo Bypass or upstream reservoirs) which are outside the purview and authority of WSAFCA to implement. Therefore, this alternative was eliminated from further consideration.

2.4 No Action Alternative

2.4.1 Introduction to No Action

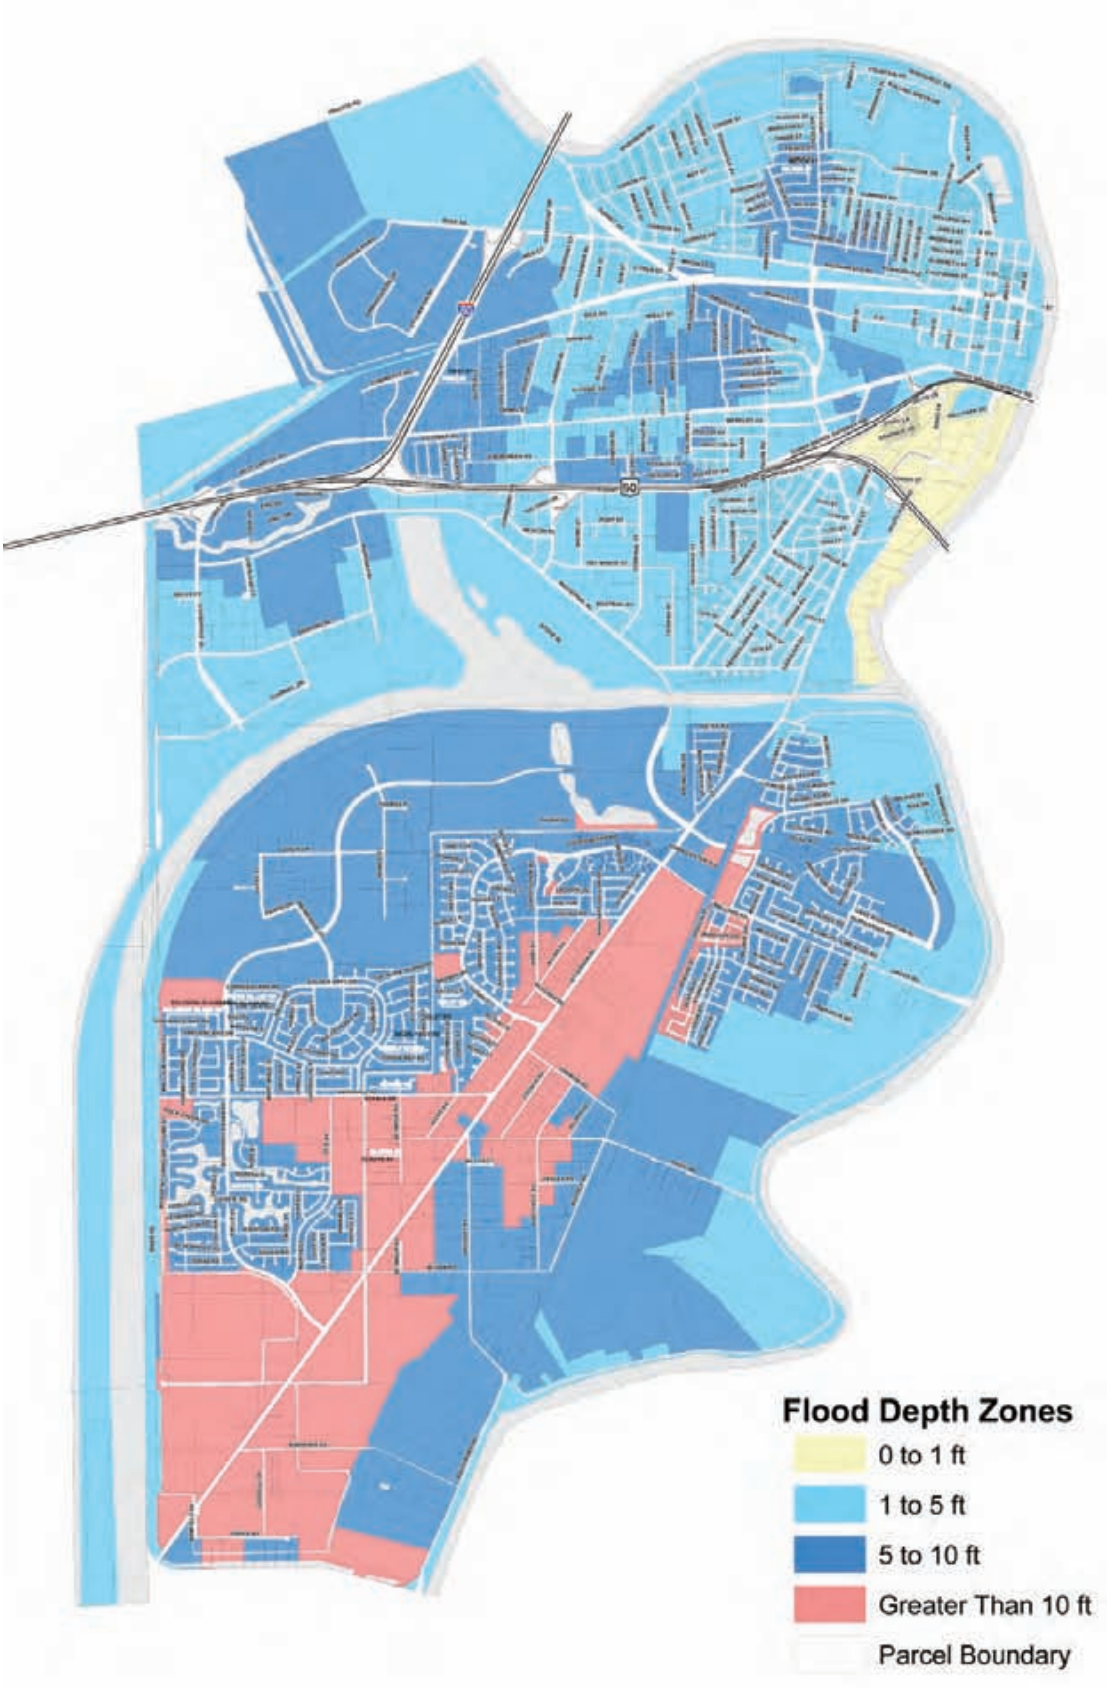
A no action alternative is required pursuant to NEPA, and a no project alternative is required for CEQA (for this EIS/EIR, collectively referred to as the No Action Alternative). The No Action Alternative serves as a benchmark against which the effects and benefits of the action alternatives

are evaluated. The No Action Alternative consists of continuation of current conditions and operation and maintenance practices that reasonably would be expected to occur in the foreseeable future if the WSLIP were not implemented based on current plans and consistent with available infrastructure and community services. This description of the No Action Alternative is intended to serve both the programmatic and project-level analyses.

2.4.2 No Flood Improvements Implemented under the No Action Alternative

Under the No Action Alternative, WSAFCA would not implement flood improvements. The levees protecting the city would continue to require improvements to meet FEMA's minimum acceptable level of flood protection. In addition, the associated risk to human health and safety, property, and the adverse economic impact that serious flooding could cause would continue, and the risk of a catastrophic flood would remain high. Again, however, regular operations and maintenance of the levee system would continue as presently executed by the local maintaining entities.

Because of uncertainties in local, state, and Federal funding; future state and Federal authorization; and other approvals, it is not reasonable to predict construction of levee improvements in the foreseeable future within a reasonable timeframe. Therefore, for the purpose of evaluating impacts under the No Action Alternative, the EIS/EIR assumes no levee repair or strengthening would be implemented, the purpose and objectives would not be met, and flood risk would continue.

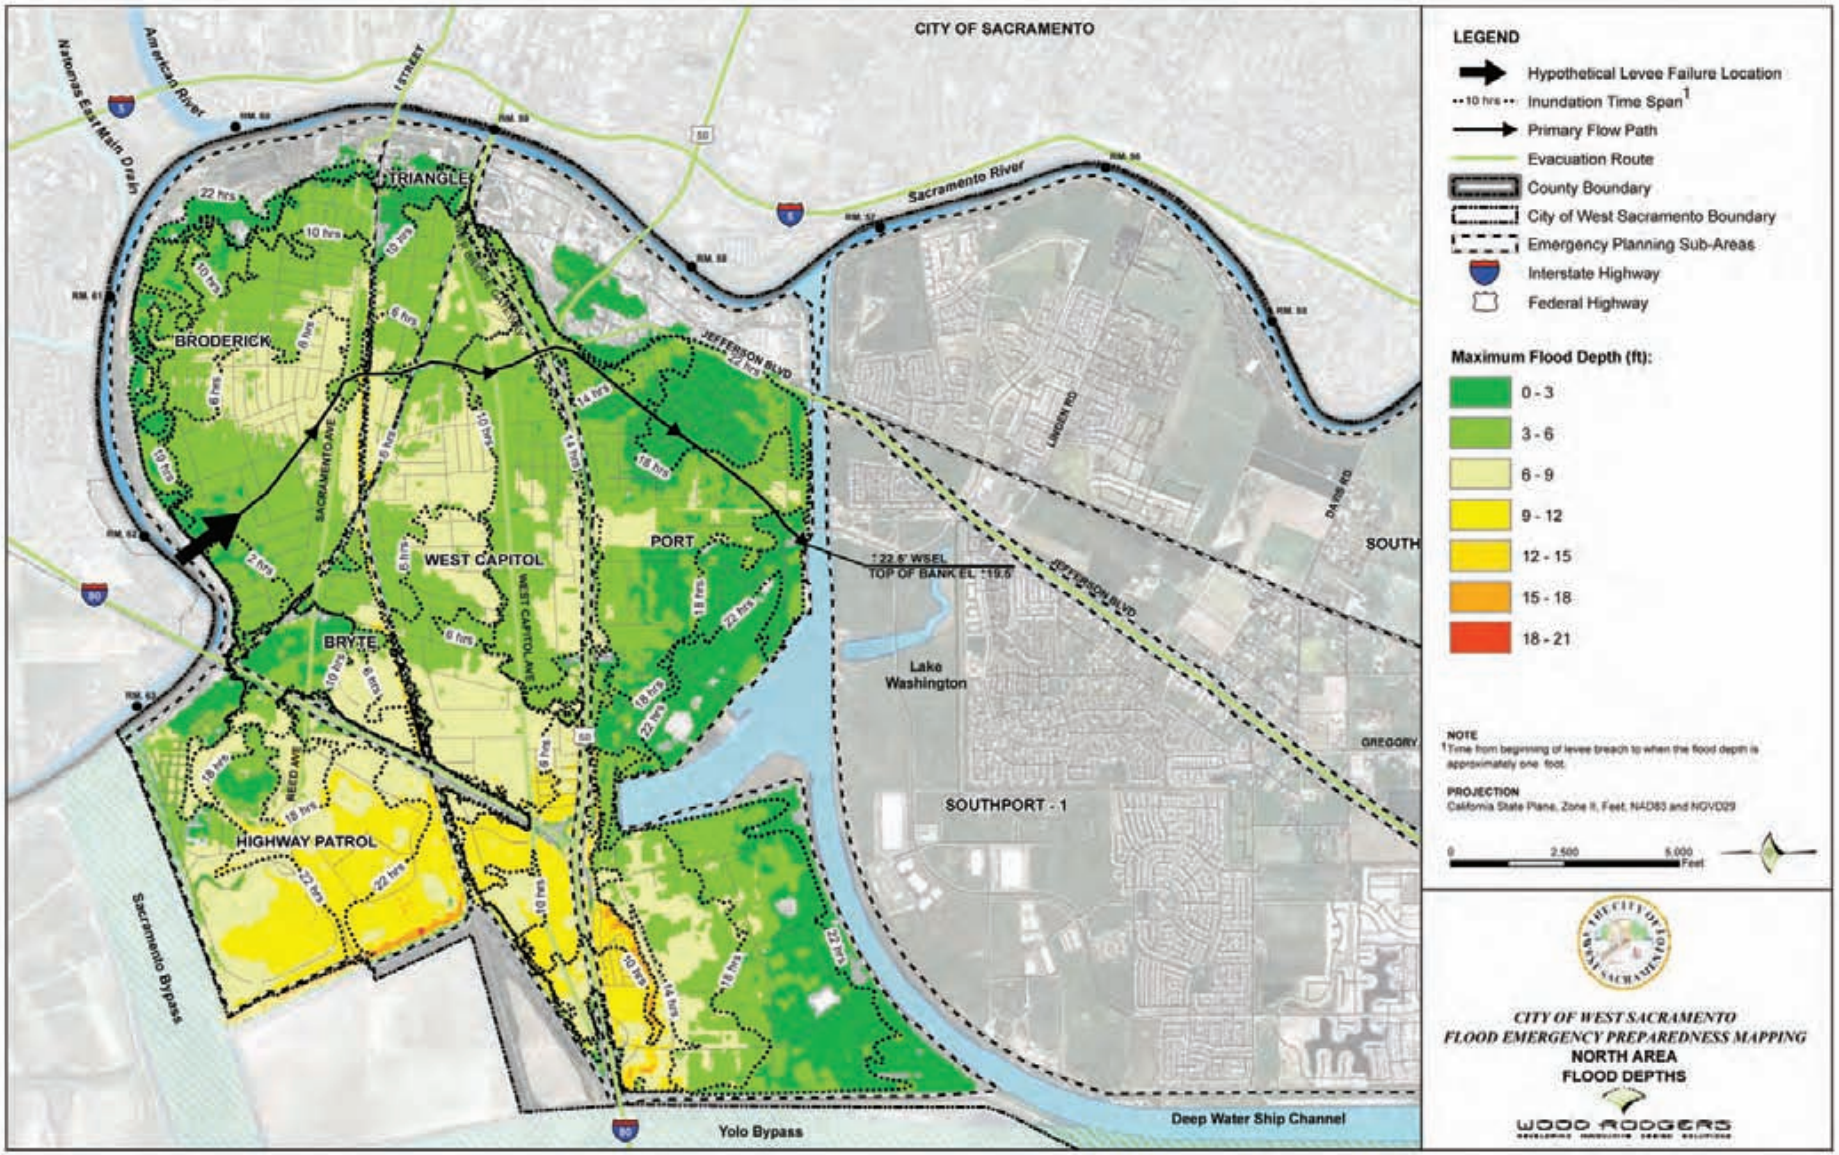


2.4.2.1 Consequences of Levee Failure

Assuming that no levee repair or strengthening would occur under the No Action Alternative means that the West Sacramento levee system would remain or become more susceptible to failure as a result of identified deficiencies such as seepage, erosion, inadequate levee height, and slope instability. These conditions could cause portions of the levee system to fail, triggering widespread flooding, extensive damage to the city's existing residential, commercial, agricultural, and industrial structures, and potential loss of life and property. Extensive damage to utilities, roadways, major interstate transportation corridors, and other infrastructure systems would also likely occur. The magnitude of the flood damage would depend upon the location of the levee breach, severity of the storm, and river flows at the time of a potential levee failure.

Flood depth maps prepared for West Sacramento indicate that under a 100-year flood event scenario, inundation levels would range from 1 foot to 15 feet, depending on the local elevation of the land surface. Figure 2-1 shows the ultimate estimated inundation depths for a 100-year flood event.

In 2006, two hypothetical levee failures were analyzed for West Sacramento utilizing 100-year water surface elevations and hydrology. This analysis was performed to assist the City in its flood emergency preparedness planning. One failure was located in the northern part of the city, on the Sacramento River North Levee, and the other was located in the Southport area, on the Sacramento River South Levee (failure locations are shown in Figures 2-2 and 2-3). (Wood Rodgers 2006.)



The analysis indicates that a levee failure on the Sacramento River North Levee during a 100-year event would flood the entire north area with at least 1foot of water within 24 hours, at which point vehicular evacuation would become severely limited (a depth of 1 foot is regarded as impassable from the standpoint of vehicular traffic). Certain neighborhoods close to the levee failure would lose

Figure 2-3
100-Year Flood Event
Estimated Time to One-Foot Inundation Depth—Southport Area

access to evacuation routes within three hours of levee failure. Figure 2-2 shows the estimated time to 1-foot inundation depths throughout the northern area. Within3 days, floodwater depths would reach 3to 10 feet, depending on land surface elevation (as shown in Figure 2-1). Floodwaters would flow from north to south, seeking the lowest topographical elevation, and eventually discharge into the DWSC. The study estimates that floodwaters would begin to spill into the DWSC less than 24 hours after the breach. Modeling indicates that the DWSC could absorb up to 20,000 cubic feet per second (cfs) in discharge flow from waters flooding the north area of the city before overtopping and flooding the Southport area. (Wood Rodgers 2006.)

A levee failure on the Sacramento River South Levee during a 100-year event would flood the entire Southport area with at least 1 foot of water within 24 hours. Jefferson Boulevard, the only vehicular evacuation route for Southport, would be inundated by 1 foot of water within 4 hours, making it impassable. Figure 2-3 shows the estimated time to 1-foot inundation depths throughout the Southport area. Inundation depth could reach 3 feet in 36 hours and 10 feet after three days (Figure 2-1). Floodwaters would flow from east to west, then turn south, collecting at the South Cross Levee. The maximum stage from the floodwater was estimated at elevation 24.57 feet. The elevation at the top of the South Cross Levee is 24.07 feet. If the South Cross Levee were overtopped, further flooding would occur downstream of the city of West Sacramento. (Wood Rodgers 2006.)

Levee failure and subsequent flooding of the city of West Sacramento would affect the entire city, jeopardizing lives, and would cause substantial damage to structures, contents, and other property such as landscaping and automobiles. As of 2005, a population of 40,439 was living in 15,448 housing units within the city (Sacramento Area Council of Governments 2008a and 2008b). All of these residents could be displaced by a catastrophic flood event. Additionally, the city is home to 30,655 jobs (Sacramento Area Council of Governments 2008c), 734 commercial and industrial structures, 46 public structures and 27 park facilities, which would all be affected by a flood event (HDR, Inc. 2009). Environmental and agricultural resources could also sustain major damage in a flood event; 22.6% of the land area within the city is either farmland or open space (City of West Sacramento 2009). If a catastrophic flood event occurred resulting in inundation up to 15 feet, land damages are estimated to be $237,763,648 and structural damages could be up to $1,750,118,102 (PB 2007). These values are based on the 100-year event.

A flood event could cause severe public health hazards as well. Flooding in the city could upset and spread stored hazardous materials, creating hazardous conditions for the public and the environment. Flood damage to homes and other structures could render them dangerous, due to structural damage as well as contamination. Additionally, the floodwaters and ponds left behind could provide a wide breeding ground for mosquitoes and other disease vectors. Effects to the water supply system could be particularly severe in a flood event, and could leave residents and businesses without a reliable water supply for a significant amount of time, as a single break in a water delivery pipe or main could contaminate the entire city's water supply. A major flood event could also result in substantial stress or disruption to the region's emergency response capacity, hospital services, and other critical lifelines of West Sacramento.

During the recovery period after a flood event, West Sacramento residents would require temporary housing, and displacement of many or all occupants would occur while levees, buildings, and other infrastructure were repaired. Businesses, social services, and other employers occupying affected structures would be forced to relocate. The potential number of displaced residents (over 40,000) and businesses (over 30,000 jobs) is so large that the demand for temporary quarters would likely exceed the available supply of vacant buildings surrounding the West Sacramento area. Thus, many

displaced residents and businesses may be forced to relocate to areas a considerable distance from West Sacramento, resulting in substantial intermediate-term and long-term economic impacts on the West Sacramento area and its people. These impacts include changes in employment numbers and patterns, business and personal incomes, tax revenues, and regional economic activity.

A flood event in West Sacramento would also disrupt state and interstate highway, rail, and shipping traffic, causing long-term effects on the region's and the state's economy and ability to move people and goods. West Sacramento has one of the most comprehensive transportation networks on the west coast. Its central geographic location and extensive north-south and east-west highway access has made it a major distribution center. High volumes of truck and passenger traffic pass through the city on Interstate 80 and US-50/Business 80 every day, with truck traffic transporting approximately $63 billion worth of cargo annually through West Sacramento (HDR Engineering 2009). Major transcontinental rail lines passing through the city provide commercial and passenger rail service to all parts of the nation, and the Port of West Sacramento runs domestic and international shipping services (City of West Sacramento 2009). Approximately 9.3 million tons of rail freight valued at approximately $5 billion travels through West Sacramento annually (HDR Engineering 2009). Flooding of this transportation and distribution infrastructure would cut off major statewide and interstate transportation corridors.

Examples of critical facilities for government and commerce in West Sacramento that would be affected by a flood event are the CHP Academy, regional distribution centers for the U.S. Postal Service and United Parcel Service, Raley Field, offices for the California Department of General Services and California State Teachers' Retirement System, the Port of West Sacramento, wastewater treatment facilities, Interstate 80, US-50, and numerous other government and commercial buildings and infrastructure. Other critical facilities and infrastructure are listed in Chapter 1 in Table 1-4.

2.4.2.2 Future State or Federal Action

As these levees have known deficiencies, and if WSAFCA were not pursuing improvements, it is likely that USACE and/or the State of California would repair the levees around the city at some time in the future in order to meet Federal and/or state flood protection obligations associated with the Federal flood control system. The study area of the West Sacramento GRR and the WSLIP are largely overlapping and address the same levee reaches. The primary objective of the GRR is to determine the extent of Federal interest in reducing the flood risk within the study area while exploring opportunities to increase recreation and restore the ecosystem along the Sacramento River. The GRR was initiated in March 2009 and is expected to be presented to Congress for authorization in 2012. The earliest that Federal levee improvements would be constructed under the GRR is 2014.

Based on the criteria used by WSAFCA to screen measures for the WSLIP and EIPs, it can be expected that actions the same as, or very similar to, those proposed and analyzed in this EIS/EIR would be considered through the West Sacramento GRR process and would be implemented by USACE or the state. The environmental effects would in turn be the same as or similar to those as analyzed in this EIS/EIR. The GRR is subject to independent NEPA review.

Despite the likelihood of state- or Federal-led implementation of repairs, for the purpose of evaluating impacts under the No Action Alternative, the EIS/EIR assumes that the improvements would not occur. This assumption provides the most conservative approach for disclosure and comparison of potential effects. Again, as stated above, the No Action Alternative therefore assumes

no levee repair or strengthening would be implemented, the purpose and objectives would not be met, and flood risk would continue.

2.4.3 Relationship of Flood Map Modernization to No Action

Further complicating the future no action scenario is the national flood map modernization process. FEMA is in the process of reevaluating the level of flood protection provided by the levee system protecting the city. The city is currently designated as falling under Zone X, meaning it has less than a 1% chance of flooding in any given year (100-year flood protection). If the city were remapped out of Zone X and into an A, AE, AR, or A-99 Zone, flood insurance would become mandatory for all citizens and businesses that hold federally guaranteed mortgage loans. In addition, Federal and state regulations would prevent or constrain further development in the city, which may further delay levee improvement funding because a flood improvement development fee is incurred for new development.

A change in the flood hazard designation for West Sacramento would interrupt the preferred regional "blueprint" for future growth through 2035 adopted by the Sacramento Area Council of Governments (SACOG) and Valley Vision in 2004. SACOG envisions that West Sacramento would be the fastest growing city in the greater Sacramento region in the coming decades because of its proximity to Sacramento's urban core and its many opportunities for reinvestment. SACOG's blueprint anticipates that more than 40,000 new dwelling units and over 50,000 new jobs will be established in West Sacramento by 2050. With a change in flood hazard designation, these 40,000 new dwelling units and the commercial and industrial developments associated with 50,000 new jobs would need to be redirected to other areas in the region over the next four decades (Sacramento Area Council of Governments 2004).

2.4.4 Levee Vegetation Policy and No Action

While the USACE review and approval process under Section 408 (which this EIS/EIR is part of) is one mechanism for review of WSAFCA's levees relative to recent USACE policy guidance for vegetation on levees, the No Action Alternative would be the same as the WSLIP, meaning the future condition is removal of non-compliant vegetation in any case. The rationale for this position is that WSAFCA would risk Federal de-certification of its levees and would risk ineligibility for Federal assistance if the USACE standards were not complied with, subject to periodic inspection. In light of these risks, it is assumed that WSAFCA's member agencies would ensure compliance in order to avoid de-certification and ineligibility for Federal assistance.

A possible mechanism for compliance with the policy is a variance or exemption authorized by USACE. USACE is developing implementation guidance for variances, and any variance would be subject to USACE approval. Variances have been conceptually discussed among the Interagency Flood Management Collaborative. This group is facilitated by DWR and is a monthly forum among DWR, USACE, USFWS, NMFS, California Department of Fish and Game (DFG), local agencies, and other resource and regulatory agencies to discuss flood management issues with an environmental focus. Subcommittees of this group were specifically formed to discuss the technical issues, policy and guidance, and possible policy variance (either of regional or local scope). At this time no variance is in place and this EIS/EIR analysis assumes no variance would be in place under the No Action Alternative.

2.4.5 Recreation under No Action

The No Action Alternative would also delay implementing elements of the Parks Master Plan, Bicycle and Pedestrian Path Master Plan, and the Sacramento Riverfront Master Plan (SRMP). The recreation corridors proposed in these plans include bike and pedestrian trails that lie on top of the levees and other recreation features that occupy the waterside and landside of the levees. It is possible or even likely that funds would not be expended to construct some or all of these features prior to the levee improvement construction activities.

2.5 Program-Level Alternatives for Levee and Flood Management Deficiencies

For each deficiency described in Chapter 1, a number of improvements or combination of improvements can be used to attain the level of flood protection desired. In some cases, more than one type of improvement can address a particular deficiency. For example, several different improvements can alleviate seepage. Conversely, one improvement may resolve more than one problem (e.g., a setback levee may solve the problems of under-seepage, stability, and erosion). In this case, the improvement is grouped by the primary deficiency it addresses, as noted below:

- levee height (for inadequate levee height),
- seepage control (for through-seepage and under-seepage),
- slope stability/geometry,
- erosion control, and
- other (for improvements that are unique or do not follow grouping conventions by deficiency).

Table 2-1 outlines the six deficiencies and the potential improvements that could be applied to resolve each deficiency; text follows describing in detail each improvement, associated construction methods, and O&M procedures, presented alphabetically in each group. Each improvement is identified in title by:

> "[Flood or Recreation] Program (deficiency addressed if part of Flood Program): [name of improvement]."

Table 2-1. Summary of Levee Improvements and Deficiencies

		Deficiency					
Group	Improvement	Inadequate Levee Height	Through-Seepage	Under-Seepage	Slope Stability and Geometry	Erosion	Non-Compliant Vegetation
Levee Height	Flood wall	✓					
	Levee raise (in place)	✓

Other	Setback levee	✓	✓		✓	✓	✓
	Vegetation removal						✓

2.5.1 Flood Program Improvements for Levee Height

2.5.1.1 Flood Program (Levee Height): Flood Wall

2.5.1.1.1 Objective

A flood wall is a freestanding concrete barrier located on the levee crown to contain unusually high surface water elevations. A flood wall addresses the levee deficiency of inadequate levee height, especially where the levee footprint is constrained or the prism cannot otherwise be enlarged.

2.5.1.1.2 Design and Construction

Flood walls are constructed of concrete and may be precast or cast in place. The existing levee crown is the working platform (Figure 2-4).

Flood walls are constructed in short spans with solid joints typical of concrete construction. To install a flood wall, the site is prepared by clearing, grubbing, and stripping any vegetation in the work area. The floodwall foundation is prepared by excavating from the waterside hinge point of the levee across its crown to a depth established based on the wall's required height. Prefabricated flood walls are delivered to the site by haul trucks, and the individual pieces of the wall are placed into a prepared foundation by a crane. To install flood walls that are cast at the site, a foundation is excavated, falsework to frame the flood wall is constructed, and concrete is poured into the falsework. After the concrete has cured sufficiently, falsework is removed and hauled away for

disposal. For both methods, excavated soil is used to refill the areas surrounding the flood wall. Any remaining soil could be hauled off site to landfills or used for levee embankment materials in other portions of the WSLIP study area (if it meets levee embankment soil criteria).

The drawback of a flood wall is that it prohibits visual and physical access to or from the waterside of the levee slope, which may inhibit O&M practices.

A complete listing of equipment and materials necessary to construct a flood wall is provided in Table 2-2. Post-construction, areas used for construction staging, the levee slopes, and any other disturbed areas would be hydroseeded.

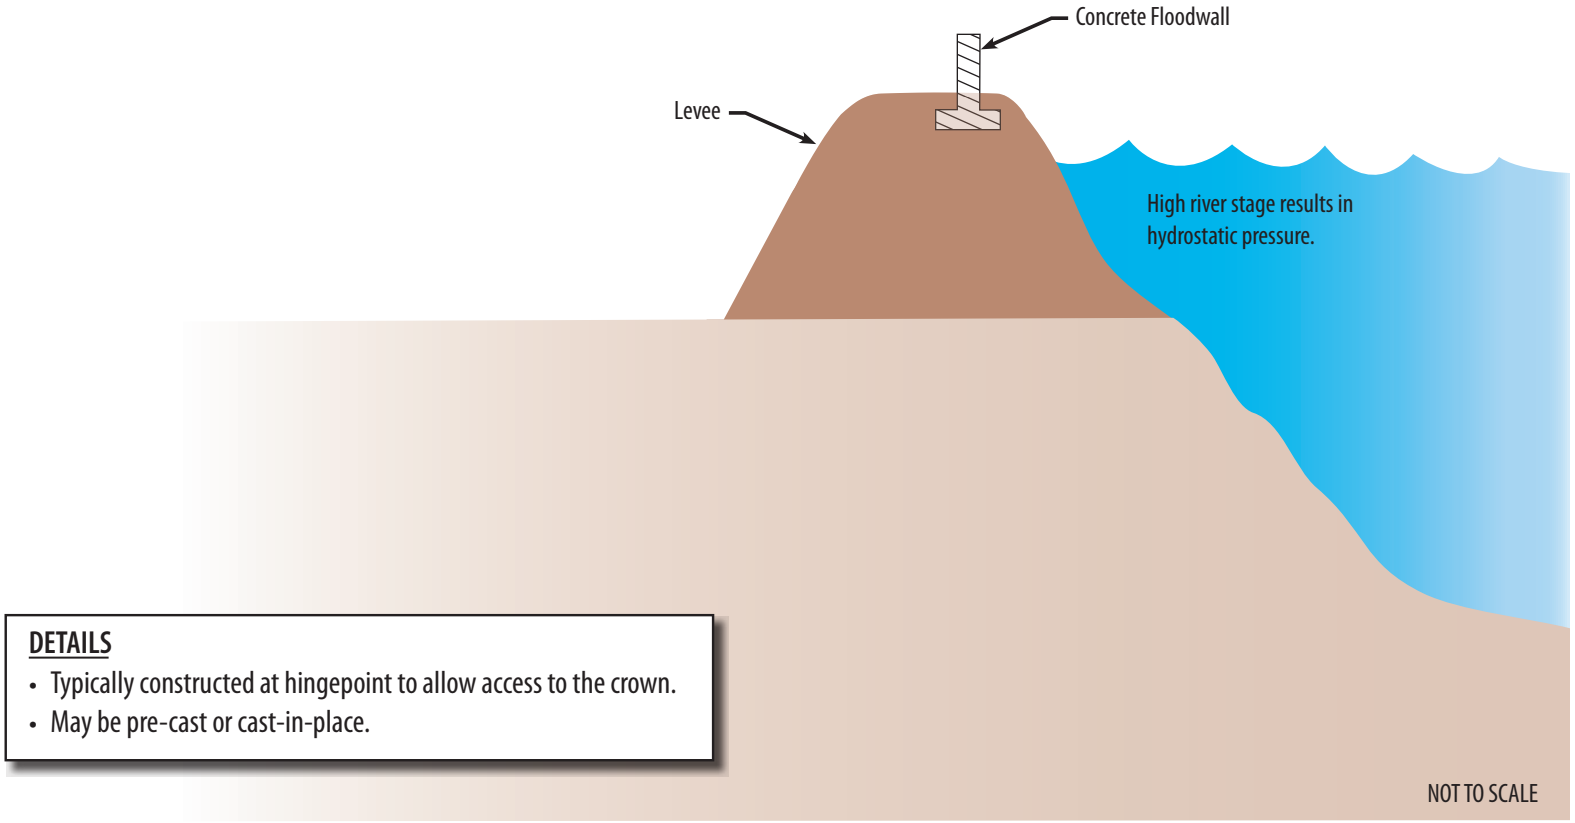
Table 2-2. Flood Wall Phases, Equipment, and Materials

Phases of Construction	Equipment	Materials
Site preparation (clearing, grubbing, and stripping)	Scraper	Prefabricated flood walls
Foundation preparation	Hydraulic excavator	Concrete (if on-site casting)
Falsework construction and cement casting or crane placement of prefabricated walls	Crane	Embankment fill material
Finish grading	Cement mixer	Water (if on-site casting)
Site restoration and demobilization	Bulldozer	Aggregate base rock
	Front end loader	Hydroseed
	Haul truck	
	Motor grader	
	Sheepsfoot roller	
	Water truck	
	Small compactor	

2.5.1.1.3 Operations and Maintenance

Post-construction, the only permanent facility is the flood wall. The wall would be inspected periodically for structural integrity and sound anchoring. Cleaning or painting may be necessary as surfaces presented by flood walls are often targets for graffiti. O&M for the levee crown, slope, and vegetation may differ from typical practices as access may be inhibited by the wall.

2.5.1.2 Flood Program (Levee Height): In-Place Levee Raise



2.5.1.2.1 Objective

An in-place (or crown-only) levee raise adds height to the existing levee without affecting the base footprint. An in-place raise can be constructed if the levee is wide enough to support the placement of additional material while maintaining adequate side slopes together with a 20-foot-minimum crown width. For this treatment, the footprint of the levee remains unchanged. The appropriateness of using an in-place, adjacent, or full levee raise is based on the condition of the existing levee prism and surrounding context and constraints. This treatment is used to address the deficiency of inadequate levee height (Figure 2-5).

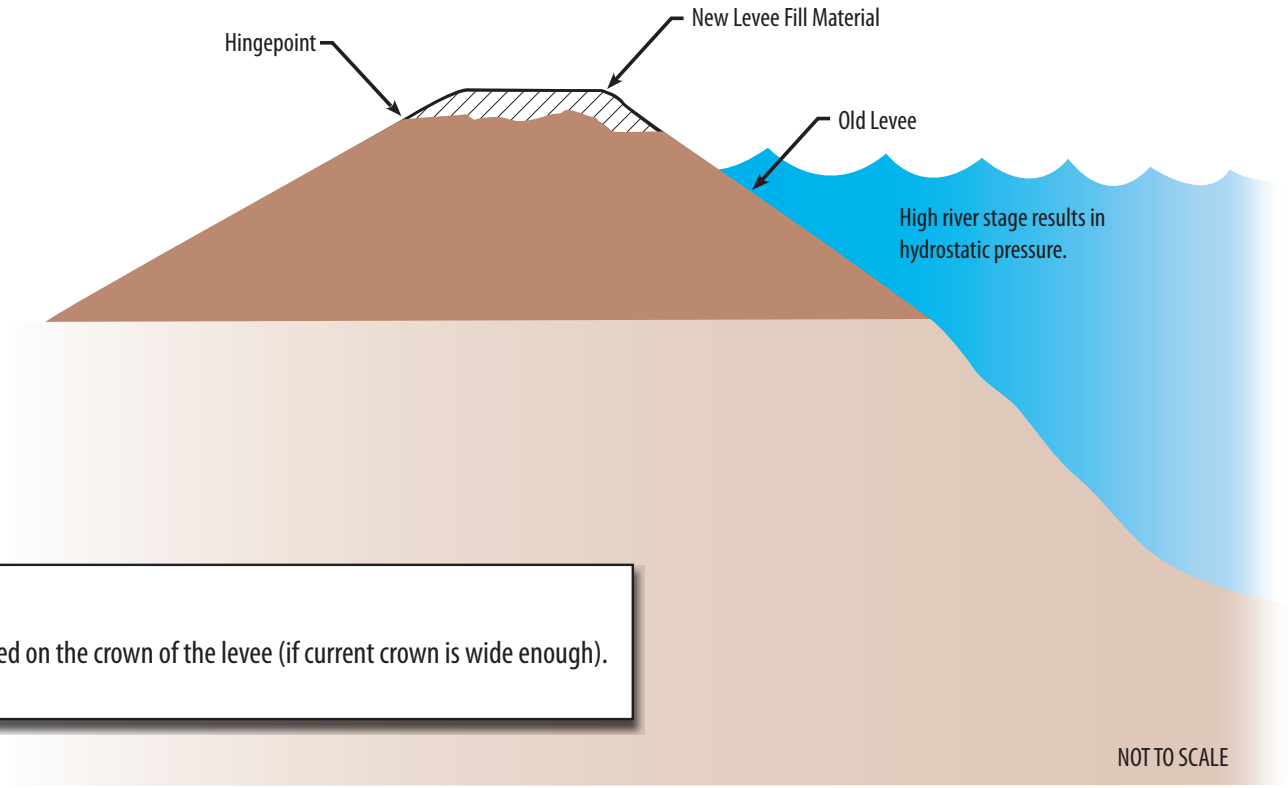
Floodwall

Concept:

Additional levee height may be achieved through construction of a concrete wall on the levee crown.

DETAILS

- Typically constructed at hingepoint to allow access to the crown.
- May be pre-cast or cast-in-place.



00875.07 EIS (9-09)

Figure 2-4
Flood Wall

In-Place Levee Raise

Concept:

Increased flood protection by adding to the crown.

DETAILS

- Material is placed on the crown of the levee (if current crown is wide enough).

00875.07 EIS (7-09)

Figure 2-5
In-Place Levee Raise

2.5.1.2.2 Design and Construction

To construct an in-place levee raise, the site is prepared by clearing, grubbing, and stripping. Bulldozers excavate and stockpile borrow material from the borrow site and load it into haul trucks with a front-end loader. Haul trucks transport embankment fill material to the site and dump it. Bulldozers position the embankment fill material along the crown of the levee, and motor graders spread the material evenly. A sheepsfoot roller typically is used to compact the material. Throughout the compaction process, water is distributed over the embankment fill material to ensure proper moisture for compaction. The slope may be track-walked with a dozer.

The levee crown is finished with an aggregate base or paved road, depending on the type and level of access desired. Either condition requires importation of material with dump trucks, placement with a loader and motor grader, and compaction. A paver is required for asphalt placement.

Equipment and materials necessary to construct an in-place levee raise are listed in Table 2-3, below. Post-construction, the levee slopes, areas used for construction staging, and any other disturbed areas are hydroseeded.

Table 2-3. Levee Raise (In-place, Adjacent, or Full)—Phases, Equipment, and Materials

Phases of Construction	Equipment	Materials
Site preparation (clearing, grubbing, and stripping)	Scraper	Embankment fill material
Material placement and rough grading	Excavator or track hoe	Aggregate base rock
Finish grading	Bulldozer	Hydroseed
Paving (optional)	Front end loader	Asphalt concrete (optional)
Site restoration and demobilization	Haul truck	
	Motor grader	
	Sheepsfoot roller	
	Water truck	
	Paver (optional)	

2.5.1.2.3 Operations and Maintenance

Post-construction, the only permanent facility is the improved levee, subject to typical O&M. Typical levee O&M in the WSLIP area currently includes the following actions:

- vegetation maintenance up to four times a year by mowing or applying herbicide;
- slope repair, site-specific and as needed, by re-sloping and compacting;
- patrol road reconditioning up to once a year by placing, spreading, grading, and compacting aggregate base or substrate; and
- visual inspection at least monthly, by driving on patrol road on the crown and maintenance roads at the base of the levee.

2.5.1.3 Flood Program (Levee Height): Adjacent Levee Raise

2.5.1.3.1 Objective

Similar to an in-place levee raise, an adjacent raise uses the existing levee as a base on which to build a higher levee with flatter slopes. The adjacent levee raise involves the construction of a new levee embankment adjacent to the existing levee. Whether to use an in-place, adjacent, or full levee raise depends on the condition of the existing levee prism and surrounding context and constraints. This treatment may address the following deficiencies:

- inadequate levee height,
- through-seepage,
- slope stability,
- erosion, and
- non-compliant vegetation.

2.5.1.3.2 Design and Construction

The adjacent raise essentially adds material to increase the cross section of the levee, thereby allowing the levee to be built to a higher elevation while allowing the prescribed 3:1 slopes and 20-foot-wide crown. The adjacent raise is typically on the landward side of the levee (Figure 2-6).

The first construction phase is clearing, grubbing, and stripping the work site and any construction staging areas, if necessary. A trapezoidal trench is cut at the toe of the slope and the levee embankment may be cut in a stair-step fashion to allow the new material to key into the existing material. Bulldozers then excavate and stockpile borrow material from a nearby borrow site. Front-end loaders load haul trucks with the borrow material, and the haul truck subsequently transport it to the adjacent raise levee site. The haul trucks dump the material and dozers spread it evenly. Sheepsfoot rollers compact the material, and water trucks distribute water over the material to ensure proper moisture for compaction. Levee slopes are graded at a 3:1 slope, and the levee crown is at least 20 feet wide. The slope may be track-walked with a dozer.

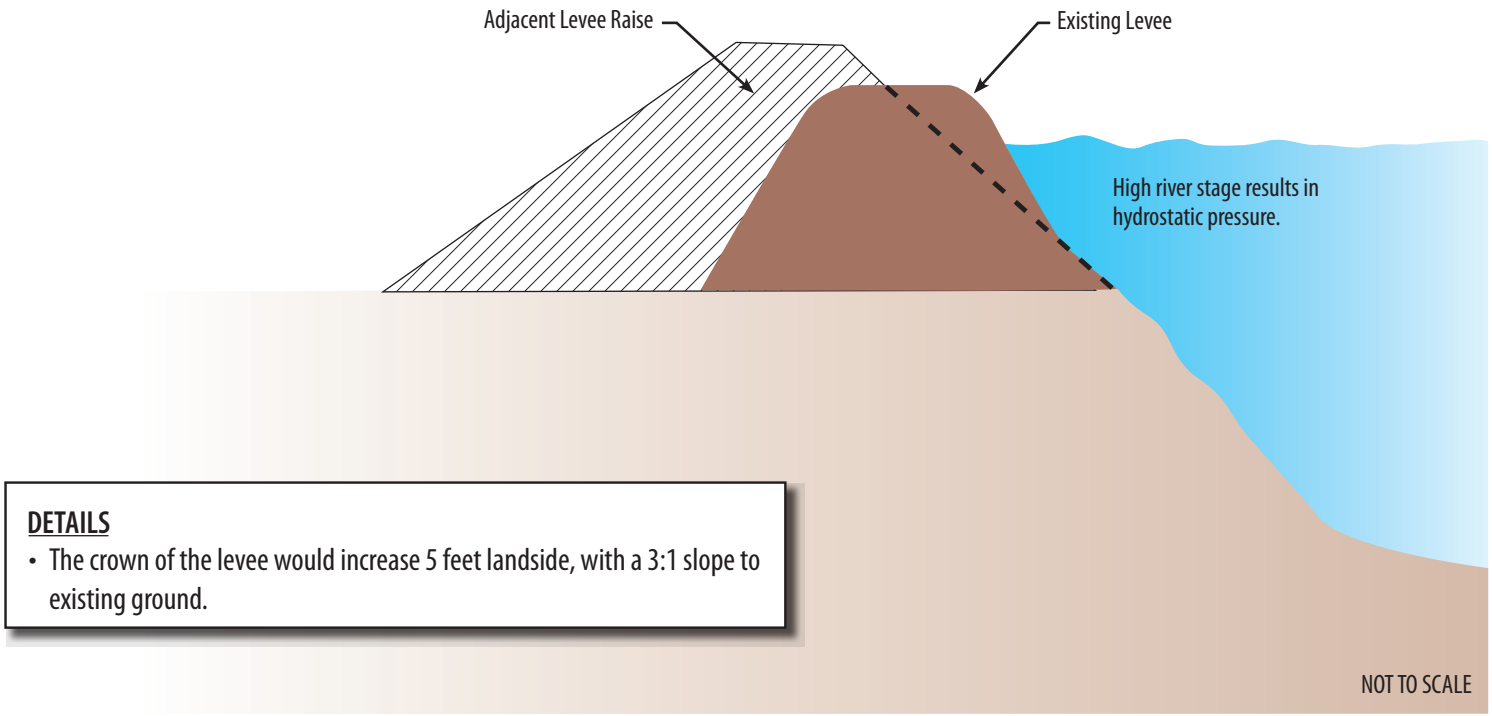
The levee crown is finished as described under the in-place levee raise.

Post-construction, the levee slopes and any other disturbed areas are hydroseeded.

2.5.1.3.3 Operations and Maintenance

Post-construction, the only permanent facility is the improved levee. O&M would be as described under the in-place levee raise.

2.5.1.4 Flood Program (Levee Height): Full Levee Raise



2.5.1.4.1 Objective

If a crown-only raise is not possible, additional height may be added to the levee by implementing a full levee raise. A full levee raise can occur on the landside, waterside, or both sides of the levee (Figure 2-7) depending on site constraints and levee conditions. Whether to use an in-place,

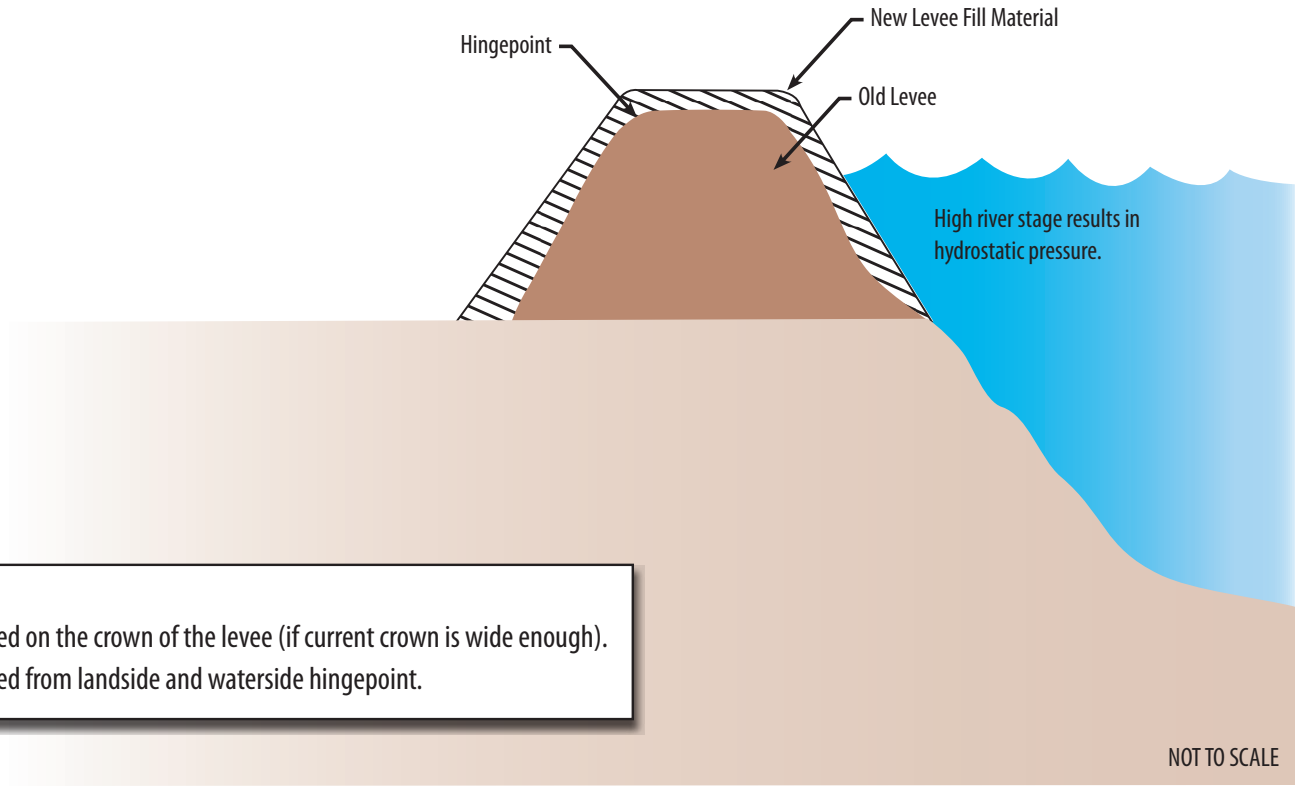
Adjacent Levee Raise

Concept:

A new embankment strengthens the existing levee and enlarges the slopes.

DETAILS

- The crown of the levee would increase 5 feet landside, with a 3:1 slope to existing ground.



00875.07 EIS (7-09)

Figure 2-6
Adjacent Levee Raise

Full Levee Raise

Concept:

Flood protection is increased by adding material to crown and levee slope (land or water side).

DETAILS

- Material is placed on the crown of the levee (if current crown is wide enough).
- Material is placed from landside and waterside hingepoint.

00875.07 EIS (7-09)

Figure 2-7
Full Levee Raise

adjacent, or full levee raise depends on the condition of the existing levee prism and surrounding context and constraints. This treatment is used to address the following deficiencies:

- inadequate levee height,
- through-seepage,
- slope stability, and
- erosion.

2.5.1.4.2 Design and Construction

A full levee raise is similar to that described under adjacent levee raise but would affect both slopes of the levee.

Equipment and materials necessary for the full levee raise are listed in Table 2-4. Post-construction, the levee slopes, construction staging areas, and any other disturbed areas are hydroseeded.

2.5.1.4.3 Operations and Maintenance

Post-construction, the only permanent facility is the improved levee. O&M would be as described under the in-place levee raise.

2.5.1.5 Flood Program (Levee Height): Closure Structure

2.5.1.5.1 Objective

A closure structure is a device to bridge a gap along the profile of the levee crown, such as where a road or railroad intersects a levee below the elevation of the levee crown. Common closure structures are stop logs and flood gates. A stop-log device involves concrete headwalls placed in the levee cross section on both sides of the gap, allowing the gap to be closed with removable concrete panels (commonly referred to as *stop logs*). The stop logs are held in place by fitting into a channel in the headwalls. A flood gate is similar to stop logs except the gap would be closed with hinged panels attached to the headwall. Stop logs are analyzed for the purposes of this document because the construction, operations, and maintenance are more involved than flood gates, as are their respective impacts. A closure structure addresses the levee deficiency of inadequate levee height.

2.5.1.5.2 Design and Construction

Clearing, grubbing, and stripping occur approximately 5 feet on either side of the proposed closure structure footprint. A trench the length and width of the structure is dug with a trencher or track hoe. I-beams are placed in concrete in the trench to provide a foundation channel to hold the bottom stop log. The stop logs are fabricated before delivery to the site and stored on site for immediate availability in the event of a flood or unusual high water event. A storage area approximately 30 feet long and 3 feet wide is cleared nearby to house the stop logs when not in use. A listing of phases and equipment and materials necessary to construct a closure structure is provided in Table 2-4.

Table 2-4. Closure Structure Phases, Equipment, and Materials

Phases of Construction	Equipment	Materials
Site preparation (clearing, grubbing, and stripping)	Scraper	Prefabricated concrete panels
Trench excavation	Trench excavator	Concrete for headwalls and closure foundation
I beam placement	Crane	Hydroseed
Storage area construction	Sheepsfoot roller	
Finish grading	Water truck	
Site restoration and demobilization	Small compactor	

2.5.1.5.3 Operation and Maintenance

A crane would be transported to the site to install stop logs when necessary. Stop logs are removed from storage and put into place until the high-water event subsides. The closure structure would be inspected periodically to ensure it is in good working order. Cleaning or painting may be necessary as surfaces of closure structures are often targets for graffiti.

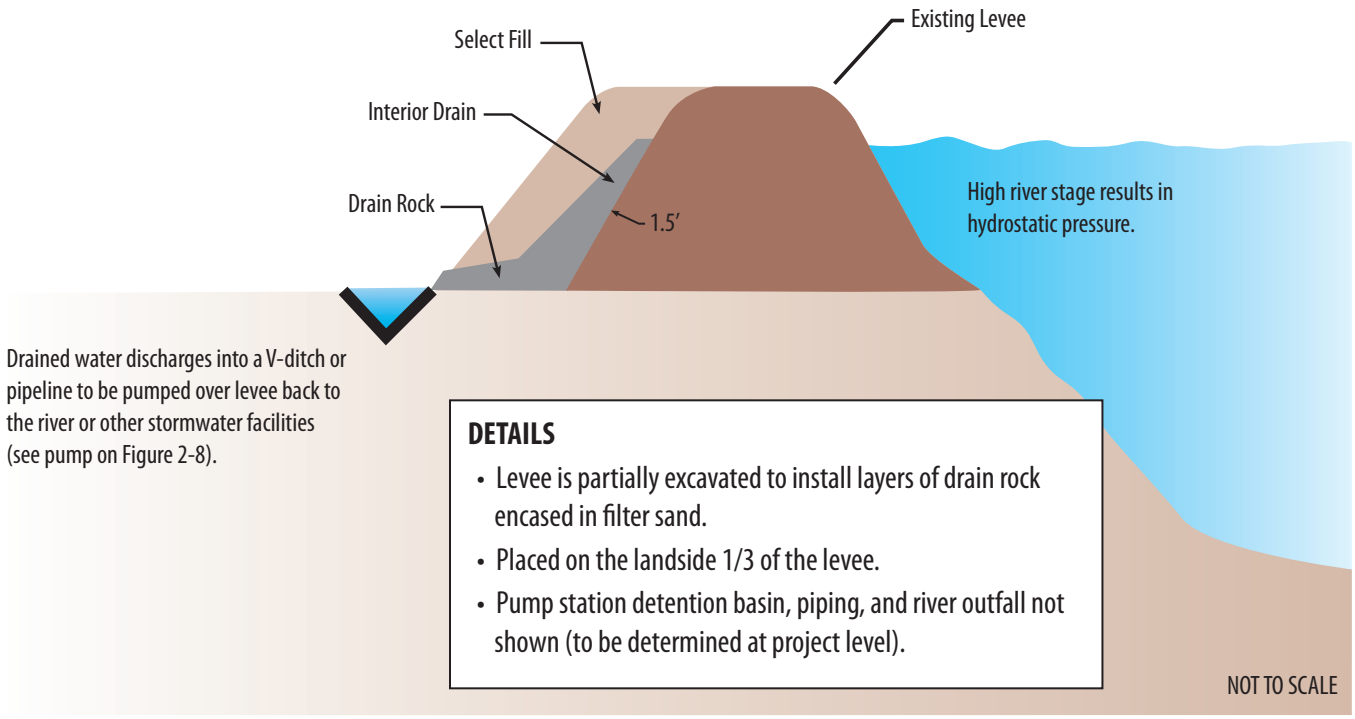
2.5.2 Flood Program Improvements for Seepage Control

2.5.2.1 Flood Program (Seepage Control): Interior Drain

2.5.2.1.1 Objective

An interior drain is a layer of drain rock encased in filter fabric or filter sand that is placed on the landside one-third of the levee prism and extends roughly 15 feet into the levee foundation. The rock provides a pervious pathway to allow and control the flow of seepage in the levee (Figure 2-8). An interior drain addresses the deficiency of through-seepage.

2.5.2.1.2 Design and Construction



To install an interior drain, the site is prepared by clearing, grubbing, and stripping the drain site and the work area. The levee then is partially excavated and a 1.5-foot-thick base layer of drain rock is placed at the levee toe, extending roughly 15 feet into the levee foundation. An additional drain layer, approximately 1.5 feet thick, runs upward and into the core of the levee at a 2H:1V slope from the end of the base layer to the approximate elevation of the design flood. A layer of geotextile material is placed over the additional drain layer, and imported embankment fill material is placed on top of the drain layer to rebuild the levee. A drainage canal is excavated at the landside levee toe to capture the water and direct it to a pump station or detention basin.

Post-construction, areas used for construction staging, the levee slope, and any other disturbed areas are hydroseeded. A listing of equipment and materials necessary to construct an interior drain is provided in Table 2-5.

Interior Drain

Concept:

Capture any through-seepage and direct it away from the face of the levee.

00875.07 EIS (9-09)

Figure 2-8
Interior Drain

Table 2-5. Interior Drain Phases, Equipment, and Materials

Phases of Construction	Equipment	Materials
Site preparation (clearing, grubbing, and stripping)	Scraper	Drain rock
Excavation and rock placement	Excavator or track hoe	Geotextile material
	Bulldozer	Embankment fill material
Finish grading	Front end loader	Aggregate base rock
Site restoration and demobilization	Haul truck	
	Motor grader	
	Sheepsfoot roller	
	Water truck	

2.5.2.1.3 Operation and Maintenance

The only post-construction permanent facility is the interior drain. Maintenance needs would involve regular inspection and repair as needed to keep the discharge point of the drain clear and flowing freely.

2.5.2.2 Flood Program (Seepage Control): Jet Grouting

2.5.2.2.1 Objective

Jet grouting involves injecting fluids or binders into the soil at very high pressure. The injected fluid can be grout; grout and air; or grout, air, and water. Jet grouting breaks up soil and, with the aid of a binder, forms a homogenous mass that solidifies over time to create a mass of low permeability (Figure 2-9). Jet grouting typically is used in constructing a slurry cutoff wall (described later in this chapter) to access areas other methods cannot. In this regard, it is typically a spot application rather than a treatment to be applied on a large scale along an entire reach. Jet grouting addresses the deficiency of seepage (through- or under-seepage).

2.5.2.2.2 Design and Construction

Equipment required for jet grouting consists of a drill rig fitted with a special drill string; a high pressure, high flow pump; and an efficient batching plant with sufficient capacity for the required amount of grout and water. The high-pressure pump conveys the grout, air, and/or water through the drill string to a set of nozzles located just above the drill bit. The diameter of the jet grout column is dependent on site specific variables such as soil conditions, grout mix, nozzle diameter, rotation speed, withdrawal rate, and grout pressure. Jet grouted columns range from one- to sixteen- feet in diameter and are typically interconnected to form cutoff barriers or structural sections. One construction crew, consisting of a site supervisor, pump operator, batch plant operator, chuck tender, and driller under ideal conditions, can construct two six-foot diameter, fifty foot columns per day consisting of approximately 100 cubic yards of grout injected per 8 hour shift. Ideal conditions would be characterized by no technical issues occurring at either the batch plant or the drilling site, such as loss of fluid pressure, breakdown of equipment, or subsurface obstructions to drilling operations.

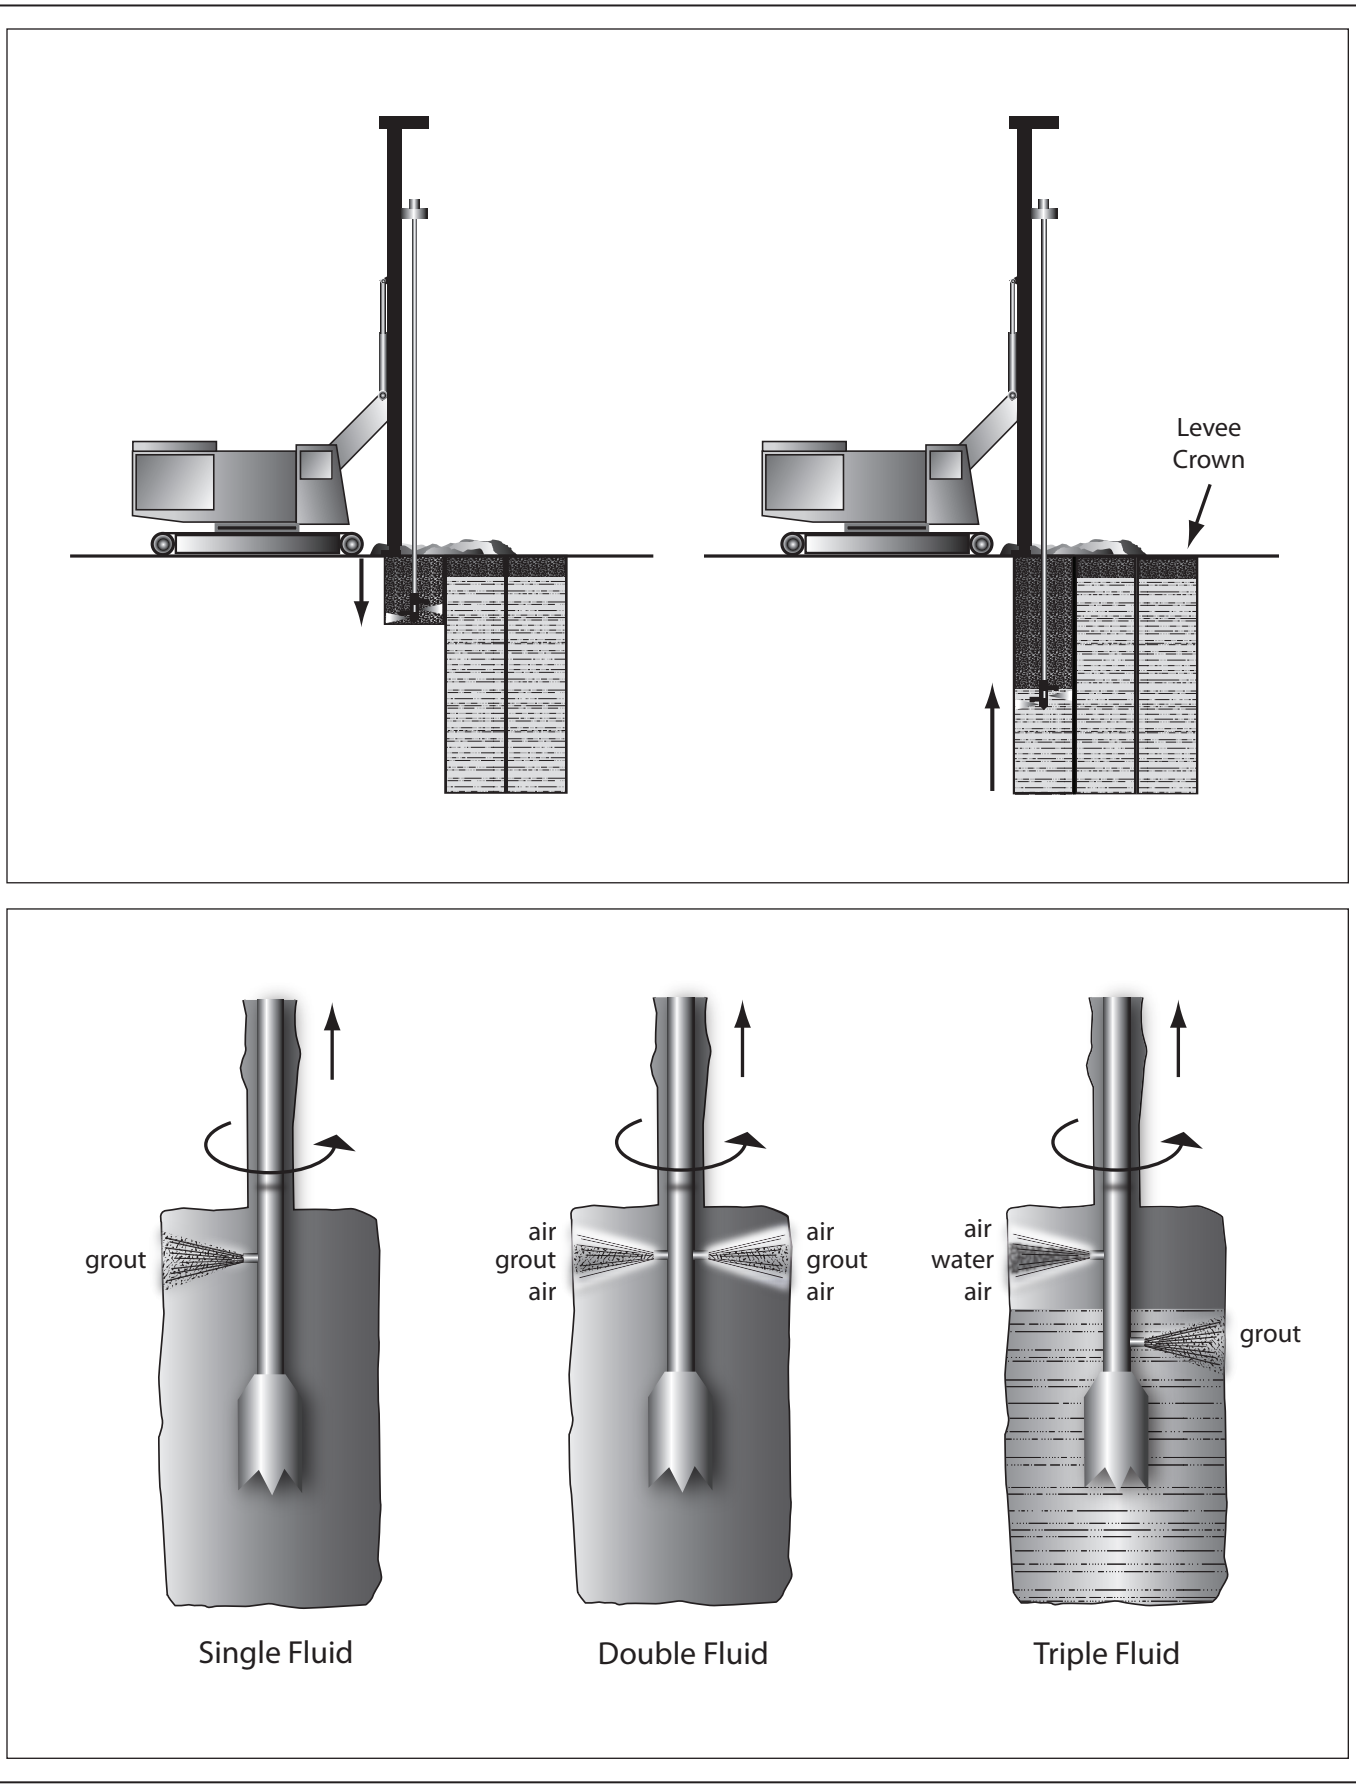
To initiate jet grouting, a borehole is drilled through the levee crown and foundation to the required depth (to a maximum depth of approximately 130 feet) by rotary or rotary-percussive methods

using water, compressed air, bentonite, or a binder as the flushing medium. When the required depth is reached, the grout is injected at a very high pressure as the drill string is rotated and slowly withdrawn. Rotation speeds range between 10 and 30 rpm and the withdrawal rates vary between 2 and 12 inches per minute. Use of the double, triple, and superjet systems create eroded spoil materials that are expelled out of the top of the borehole. The spoil material contains significant grout content and is frequently used as a construction fill.

To provide a wide enough working platform on the levee crown, the upper portion of some segments of the levee may require degradation with a paddle wheel scrapper. Material is scraped and stockpiled at a nearby stockpile area. Hauling at the work area involves scraper runs along the levee to the staging area and grout, bentonite, and water deliveries to the batch plant.

Batch plants are typically centrally located to the injection site, with pipelines for mixed grout that run the length of the work. Grout mixing and injection equipment consists of grout mixers, high powered grout pumps and supporting generators and air compressors, holding tanks, water tanks, with bulk silos of grout typically used to feed large mixers. Smaller equipment can be used in combination with the single phase-fluid system and can be permanently trailer mounted to permit efficient mobilization and easy movement at the job site.

Prior to commencing production jet grouting, a field test program is typically completed to evaluate injection parameters and to assess jet grout column geometries, and mechanical and permeability properties. Where possible, jet grout test elements are exposed by excavation and properties are obtained by direct measurement. Bulk samples are collected and delivered to a laboratory for unconfined compressive strength and permeability testing, as required. Where excavation is not possible, core drilling is employed to obtain samples from the jet grout test columns for strength testing.



Types of Jet Grouting Systems

A single phase jet grouting system uses the binder to break up and provide soil mixing of the soils surrounding the drill rods. The single jet grouting system is the most versatile; it can be applied at any inclination and in areas where space is restricted. Set up and excavation times are considerably shorter; the method is also less expensive, cleaner, and less noisy than the 3-fluid jet grouting system.

A double phase jet grouting system improves the range of influence of the single phase jet grouting system using an aureole of compressed air concentric about the jet of binder. The diameter of a column of soil treated by the single phase jet grouting system can be increased by adding the air component. Additional equipment includes a 2-way coaxial drill string and an air compressor.

The triple phase or Kajima jet grouting system uses water and air to break up the soil to produce partial substitution of the finer soil particles to create a column of stabilized material whose diameter may exceed 6 feet. Additional equipment includes a 3-way coaxial drill string, an air compressor, and an additional pump and lines for the water phase.

The superjet grouting system is a modified double phase jet grouting system that uses tooling design efficiencies and increased energy that allows for the construction of large columns, up to 16 feet in diameter. The superjet system operates by mechanically and hydraulically focusing the injection of the grout for pinpoint cutting and erosion of very large volumes of soil in situ. The excess soil-grout mixture is simultaneously expelled at the surface, preventing subsurface pressurization and

00875.07 EIR (9-09)

Jet Grouting Diagrams

hydrofracturing. A listing of equipment and materials necessary to construct the jet grouting system is provided in Table 2-6.

Table 2-6. Jet Grouting Phases, Equipment, and Materials

Phases of Construction	Equipment	Materials
Site preparation (clearing, grubbing, and stripping)	Scraper	
Work Platform excavation	Excavator or track hoe	
Jet Grouting	Jet grouting drill rig	
	Mobile batch plant	Cement, bentonite
	High pressure, high flow pump	Water
	Piping from drill rig to batch plant (spoil line)	
	Piping from batch plant to drill rig	
Replacement of levee material	Bulldozer	Water
Finish grading	Front end loader	
Site restoration and demobilization	Haul truck	Miscellaneous construction support materials
	Paddle wheel scraper	Embankment fill material
	Water truck	

Areas used for construction staging, the levee slope, and any other disturbed areas are restored and hydroseeded following construction.

2.5.2.2.3 Operation and Maintenance

Post-construction, the only permanent facility is the seepage cutoff barrier. The only O&M activity would be observation for seepage during high-water events.

2.5.2.3 Flood Program (Seepage Control): Relief Wells

2.5.2.3.1 Objective

Relief wells are passive systems that are constructed near the levee landside toe to provide a low-resistance pathway for under-seepage to exit to the ground surface in a controlled and observable manner (Figure 2-10). A low-resistance pathway allows under-seepage to exit without creating sand boils or piping levee foundation materials. Relief wells are an option only in reaches where geotechnical analyses have identified continuous sand and gravel layers. Relief wells are used to address the levee deficiency of under-seepage.

2.5.2.3.2 Design and Construction

Relief wells are constructed using soil-boring equipment to drill a hole vertically through the fine-grained blanket layer (sand) into the coarse-grained aquifer layer (gravel) beneath. Pipe casings and gravel/sand filters are installed to allow water to flow freely to the ground surface, relieving the pressure beneath the clay blanket without transporting fine materials to the surface, which can

undermine the levee foundation. The water then is collected in a v-ditch or similar drainage structure, detained, and pumped back into the river.

Relief wells generally are spaced at 50- to 100-foot intervals, dependent upon the amount of under-seepage, and extend to depths of up to 150 feet. Areas for relief well construction are cleared, grubbed, and stripped. During relief well construction, a typical well-drilling rig is used to drill to the required depth and construct the well (including well casing, gravel pack material, and well seal) beneath the ground surface. The drill rig likely would be an all-terrain, track-mounted rig that could access the well locations from the levee toe.

Areas along the levee toe may be used to store equipment and supplies during construction of each well. Construction of each well and the lateral drainage system typically takes 10 to 20 days. Additional time may be required for site restoration.

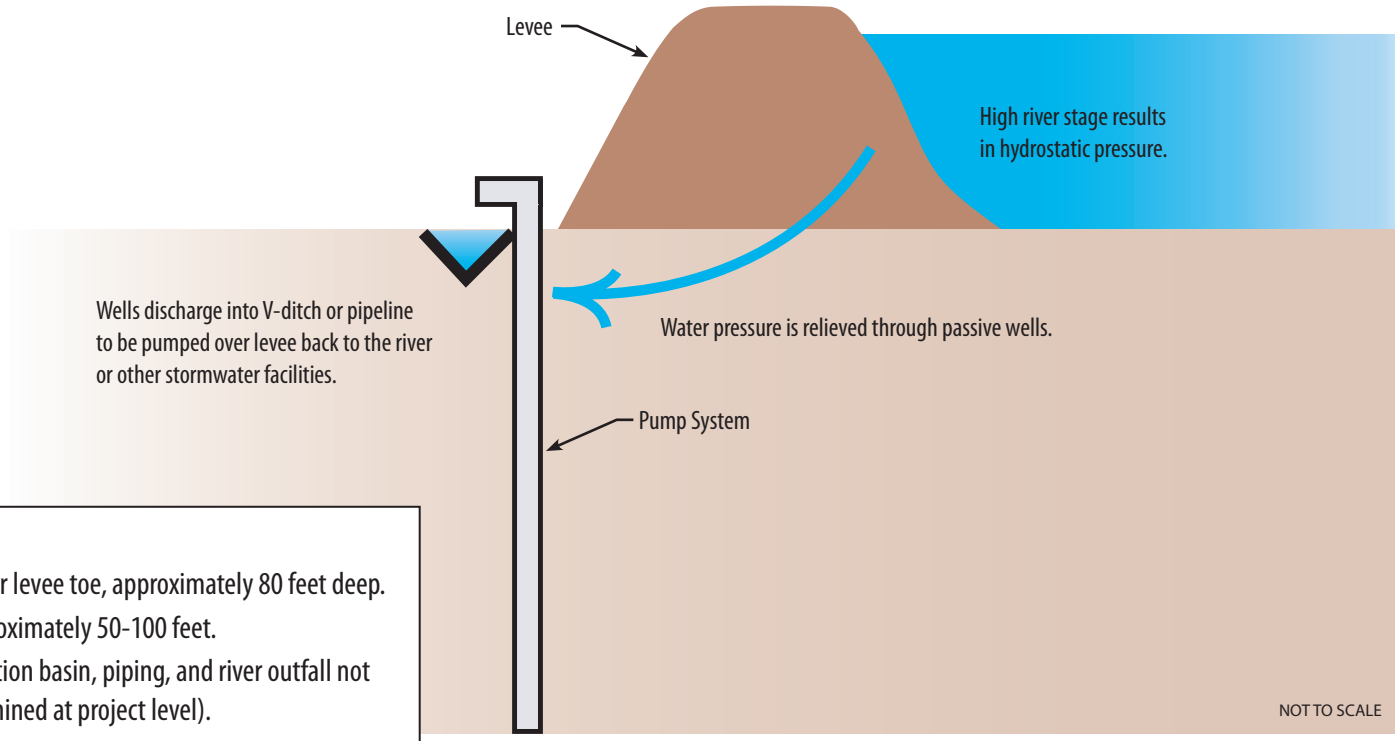
Equipment and materials necessary to construct a relief well are listed in Table 2-7.

Table 2-7. Relief Wells—Phases, Equipment, and Materials

Phases of Construction	Equipment	Materials
Site preparation (clearing, grubbing, and stripping)	Scraper	Well casing
Drilling and well installation	Trench excavator or track hoe	Sand and gravel
Finish grading	Drill rig	Concrete
Site restoration and demobilization	Equipment support vehicle	Drain pipe
	Haul truck	Hydroseed
	Motor grader	
	Sheepsfoot roller	
	Water truck	
	Small compactor	

Post-construction, areas used for construction staging, the levee slopes, and any other disturbed areas are hydroseeded.

2.5.2.3.3 Operation and Maintenance



Relief wells require regular maintenance to ensure proper operation. Piezometers, also called monitoring wells, could be installed between relief wells to allow monitoring of groundwater levels to ensure the wells are relieving the pressure within the aquifer.

Permanent facilities associated with relief wells include the wells themselves, associated lateral drains, and the pump station. Inspection of the relief wells is required at least annually, and observation of flow from the wells is required during high river stages. The wells are test-pumped every 2 years, and the discharge water from those tests is trucked off site to a central disposal, if necessary. The collection ditch is maintained to allow free flow of water.

Relief Wells

Concept:

Water pressure is relieved via passive wells, which control water discharge into a collection system.

DETAILS

- Wells are drilled near levee toe, approximately 80 feet deep.
- Well spacing is approximately 50-100 feet.
- Pump station detention basin, piping, and river outfall not shown (to be determined at project level).

00875.07 EIS (9-09)

Figure 2-10
Relief Wells

2.5.2.4 Flood Program (Seepage Control): Seepage Berm

2.5.2.4.1 Objective

Seepage berms are wide embankment structures made up of low-permeability materials that resist accumulated water pressure and safely release seeping water (Figure 2-11). A seepage berm is typically one-third the height of the levee, extending outward from the landside levee toe approximately 300 to 400 feet, and laterally along the levee as needed relative to the seepage conditions. A seepage berm addresses the deficiency of under-seepage.

There are two types of berms that could be constructed as part of the WSLIP: (1) hybrid and (2) semi-pervious berms.

2.5.2.4.2 Hybrid Berm

Design and Construction

A hybrid berm is a seepage berm with a layer of drain rock along the ground surface underneath random fill material. Hybrid berms can vary in width between four times the levee height or 100 feet (minimum) and 300 feet (maximum). Lateral length is dependent on seepage conditions along the levee. A typical 100-foot-wide berm has a height of 5 feet at the landside levee toe tapering off to 3 feet at the end of the berm. A typical 300-foot-wide berm tapers from 7.5 feet at the levee landside toe to 3 feet at the end.

Construction consists of clearing, grubbing, and stripping the ground surface and placing a 1-foot-thick layer of drain rock across the ground surface. Bulldozers then excavate and stockpile borrow material from a nearby borrow site. Front-end loaders load haul trucks, and the haul trucks subsequently transport the borrow material to the hybrid berm site. The haul trucks dump the material and motor graders spread it evenly, placing approximately 3 to 5 feet of embankment fill material over the drain rock. Sheepsfoot rollers compact the material, and water trucks distribute water over the material to ensure proper moisture for compaction.

Equipment and materials necessary to construct a hybrid berm are listed in Table 2-8.

Table 2-8. Hybrid Berm—Phases, Equipment, and Materials

Phases of Construction	Equipment	Materials
Site preparation (clearing, grubbing, and stripping)	Scraper	Embankment fill material
Drain rock and embankment fill material placement	Excavator or track hoe	Drain rock
	Bulldozer	Water
Finish grading	Front end loader	Aggregate base rock
Site restoration and demobilization	Haul truck	Hydroseed
	Motor grader	
	Sheepsfoot roller	
	Water truck	

Post-construction, areas used for construction staging, the levee, the berm, and any other disturbed areas are hydroseeded.

Operation and Maintenance

The only post-construction permanent facility is the berm. Maintenance of the berm would be similar to the typical O&M practices for levee slopes as described under in-place levee raise.

2.5.2.4.3 Semi-Pervious Berm

Design and Construction

Semi-pervious berms are similar to hybrid berms without the layer of drain rock. Semi-pervious berms vary from 150 to 400 feet in width. Typical height of the berm is 9 feet at the levee landside toe and it tapers to 4 feet at the berm toe, regardless of the berm width. Lateral length depends on seepage conditions along the levee reach.

Construction consists of clearing, grubbing, and stripping the ground surface. Bulldozers excavate and stockpile borrow material from a nearby borrow site. Front-end loaders load haul trucks, and the haul trucks subsequently transport the borrow material to the hybrid berm site. The haul trucks dump the material and motor graders spread it evenly, placing approximately 4 to 9 feet of embankment fill material. Sheepsfoot rollers compact the material and water trucks distribute water over the material to ensure proper moisture for compaction.

Equipment and materials necessary to construct a semi-pervious berm are listed in Table 2-9.

Table 2-9. Semi-Pervious Berm—Phases, Equipment, and Materials

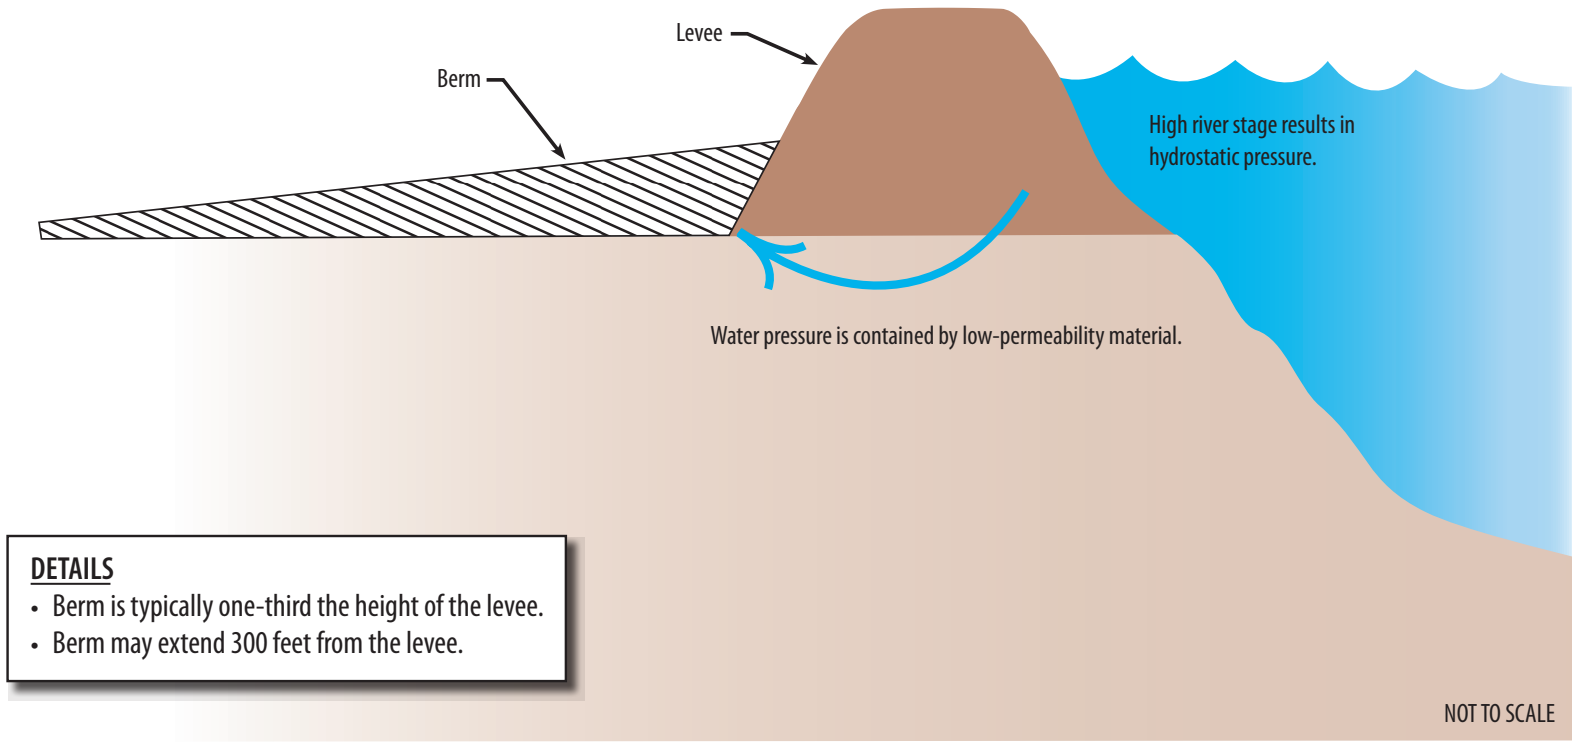
Phases of Construction	Equipment	Materials
Site preparation (clearing, grubbing, and stripping)	Scraper	Embankment fill material
Embankment fill material placement	Excavator or track hoe	Water
Finish grading	Bulldozer	Aggregate base rock
Site restoration and demobilization	Front end loader	Hydroseed
	Haul truck	
	Motor grader	
	Sheepsfoot roller	
	Water truck	

Areas used for construction staging, levee slopes, the berm, and any other disturbed areas are hydroseeded.

Operation and Maintenance

The only post-construction permanent facility is the berm. Maintenance of the berm would be similar to the typical O&M practices for levee slopes as described under in-place levee raise.

2.5.2.5 Flood Program (Seepage Control): Sheet Pile Wall



2.5.2.5.1 Objective

A sheet pile wall is a series of vertical panels of interlocking steel that is placed parallel to the levee, typically through the center of the levee crown to provide an impermeable barrier (Figure 2-12). A sheet pile wall addresses the deficiencies of seepage (through- and under-seepage).

Seepage Berm

Concept:

Water pressure is contained and dispersed by a thickened soil layer.

00875.07 EIS (7-09)

Figure 2-11
Seepage Berm

2.5.2.5.2 Design and Construction

The site where sheet piles are to be installed is cleared, grubbed, and stripped to allow for construction activities. A hydraulic- or pneumatically operated pile- driving head attached to a crane drives the sheet pile into the levee crown to the desired depth (up to 135 feet). If the levee material is particularly solid, pre-drilling may be necessary. The conditions of the site and the desired life of the project determine the thickness and configuration of the sheet piles.

Equipment and materials necessary to construct sheet piles are listed in Table 2-10. Post-construction, construction staging areas, the levee crown, slopes, and any other disturbed areas are hydroseeded.

Table 2-10. Sheet Pile Wall—Phases, Equipment, and Materials

Phases of Construction	Equipment	Materials
Site preparation (clearing, grubbing, and stripping)	Scraper	Sheet-Sheet pile walls
Pile driving of sheet piles	Excavator or track hoe	Water
Finish grading	Front end loader	Aggregate base rock
Site restoration and demobilization	Haul truck	Hydroseed
	Crane	
	Water truck	

2.5.2.5.3 Operation and Maintenance

The only post-construction permanent facility is the sheet pile wall. The only O&M activity would be observation for seepage during high-water events.

2.5.2.6 Flood Program (Seepage Control): Slurry Cutoff Wall

2.5.2.6.1 Objective

A slurry cutoff wall consists of impermeable material that is placed parallel to the levee, typically through the center of the levee crown (Figure 2-13). There are two methods for constructing a slurry cutoff wall: (1) conventional slot trench and (2) deep soil mixing (DSM). Either method could be used to construct slurry cutoff walls in the WSLIP study area. A slurry cutoff wall addresses the deficiency of seepage (through- and under-seepage).

2.5.2.6.2 Conventional Slot Trench Method

Design and Construction

To begin construction, the construction site and any necessary construction staging or slurry mixing areas are cleared, grubbed, and stripped.

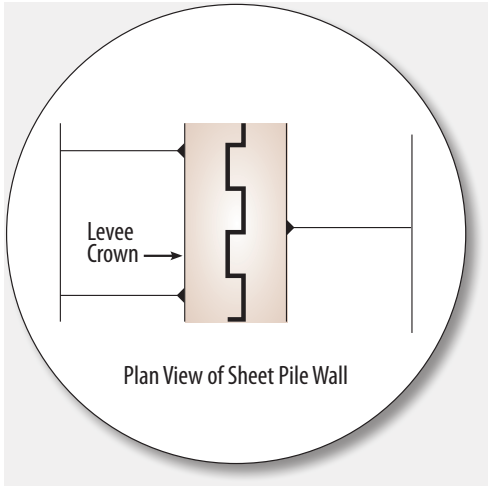
In the conventional slot trench method, a trench is excavated at the top center of the levee and into subsurface materials. The size of the trench is based on the severity of the seepage but can be typically 3 feet wide and up to 140 feet deep. As the trench is excavated, it is filled temporarily with bentonite water slurry to prevent cave in. The soil from the excavated trench then is hauled to a nearby location where it is mixed with hydrated bentonite to reduce permeability and cement in

some applications where increased strength is desired. The soil-bentonite mixture then is returned to the levee and backfilled into the trench. This mixture hardens and creates the impermeable barrier wall in the levee.

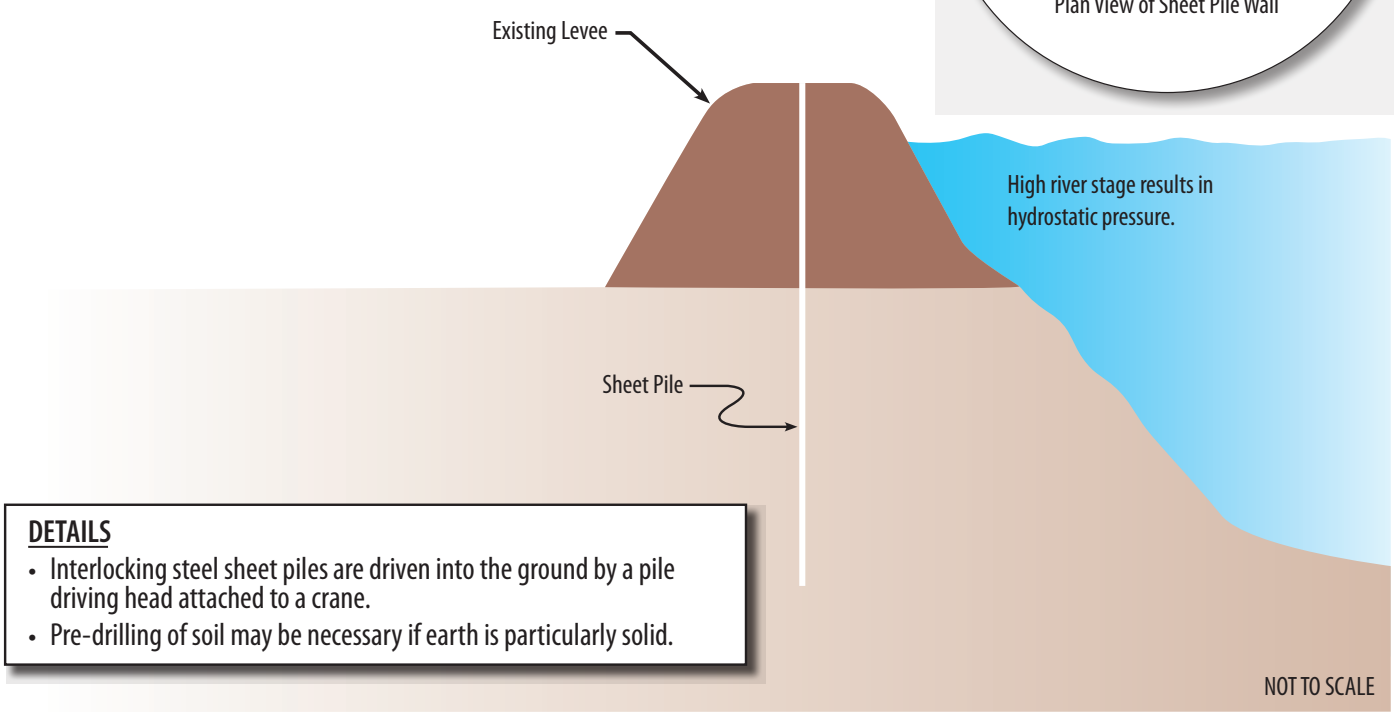
In most cases, degradation of the levee crown is necessary to create a large enough working platform and reduce the risk of hydraulic fracturing from the insertion of slurry fluids, also allowing greater depths to be reached. Dependent on the conditions of the particular levee, it may be necessary to degrade the levee by one- to two-thirds its existing height. The excavated material is hauled to a nearby stockpile area. Following completion of the slurry cutoff wall, the material is hauled back to the levee to restore the levee to its original dimensions. The material may need to be hauled offsite and borrow material may need to be imported if the in-situ levee material is found to be unsuitable for current levee standards.

One construction crew typically is able to construct 40 to 50 linear feet of slurry wall (approximately 70 to 80 feet deep) in an 8-hour shift. Equipment needed for the crew includes a long-reach track hoe, three or four dump trucks (15-cubic- yard capacity each), two loaders at the mixing location, bulldozers, excavators, loaders, a rough terrain forklift, compactors, maintainers, and a water truck. Vertical clearance of about 40 feet is needed for the excavator boom. Horizontal clearance of about 30 feet beyond the levee crest may be required for excavator swing when loading dump trucks.

A mixing area is located at the construction staging area. The mixing area is to prepare the soil-bentonite mixture and supply bentonite-water slurry. The mixing area is contained to avoid inadvertent dispersal of the mixing materials. Dump trucks haul material between the excavator and the mixing area along the levee.



An access road made of aggregate base rock is constructed on the levee crown to enable regular levee inspections.



A listing of the construction equipment and materials necessary to construct a slurry cutoff wall by this method are listed in Table 2-11. Post-construction, areas used for construction staging, mixing, the levee crown, slopes, and any other disturbed areas are hydroseeded.

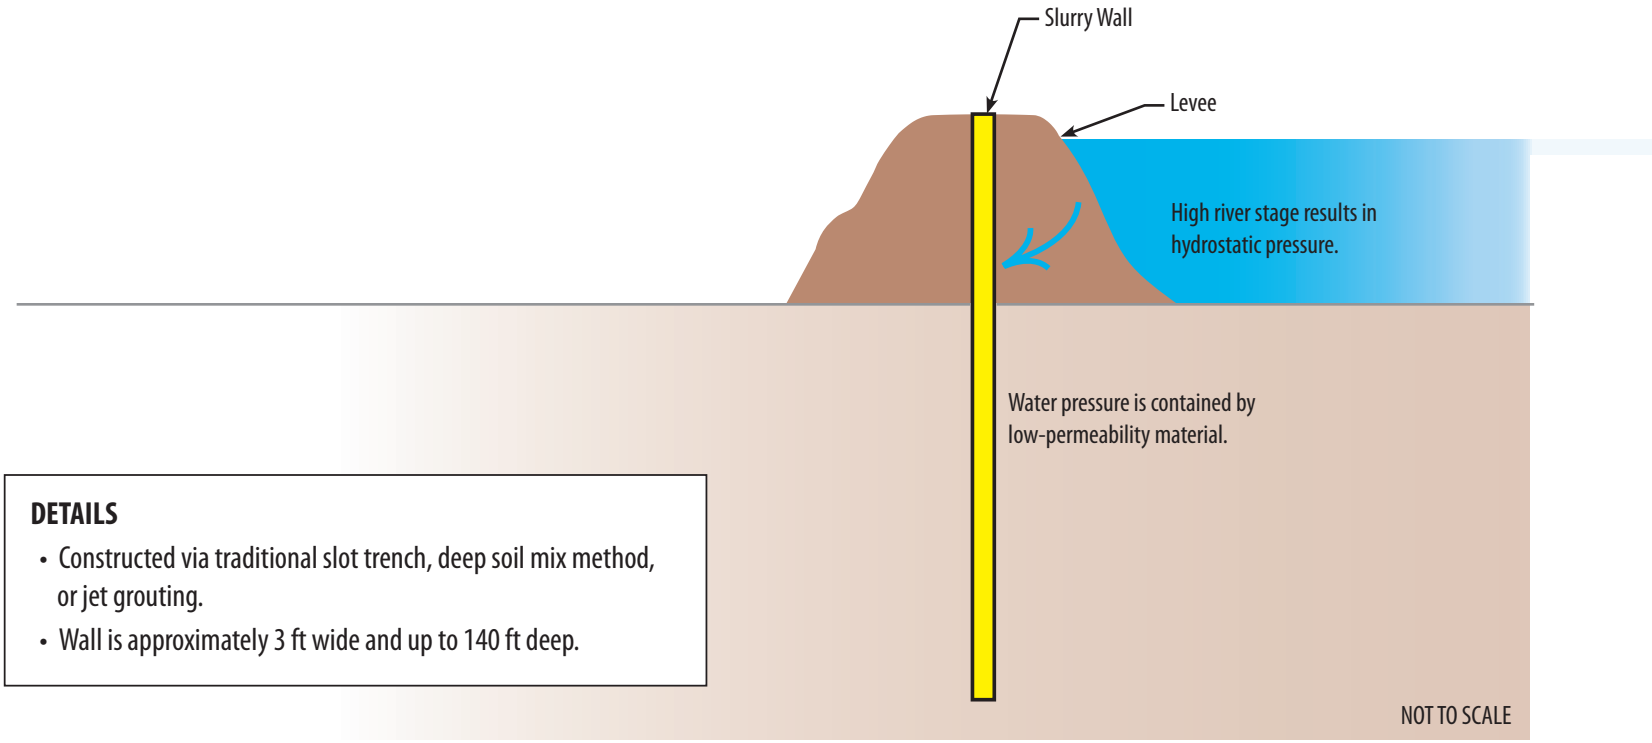
Sheet Pile Wall

Concept:

Steel panels are driven into the levee core to provide a seepage barrier.

DETAILS

- Interlocking steel sheet piles are driven into the ground by a pile driving head attached to a crane.
- Pre-drilling of soil may be necessary if earth is particularly solid.



00875.07 EIS (7-09)

Figure 2-12
Sheet Pile Wall

Slurry Cutoff Wall

Concept:

Water pressure is contained and dispersed by a low-permeability wall constructed within the levee cross section.

DETAILS

- Constructed via traditional slot trench, deep soil mix method, or jet grouting.
- Wall is approximately 3 ft wide and up to 140 ft deep.

00875.07 EIS (7-09)

Figure 2-13
Slurry Cutoff Wall

Table 2-11. Conventional Slot Trench Slurry Wall—Phases, Equipment, and Materials

Phases of Construction	Equipment	Materials
Site preparation (clearing, grubbing, and stripping)	Scraper	Cement
Work platform and trench excavation	Excavator or track hoe	Bentonite
Mixing/placement of soil bentonite mix	Long reach track hoe	Aggregate base rock
Replacement of levee material	Bulldozer	Hydroseed
Finish grading	Front end loader	Water (if no available domestic supply)
Site restoration and demobilization	Haul truck	
	Compactor	Miscellaneous construction support materials
	Maintainer	Embankment fill material (if existing material is of poor quality)
	Water truck	
	Rough terrain forklift	

Operations and Maintenance

Post-construction, the only permanent facility is the slurry cutoff wall. The only O&M activity would be observation for seepage during high-water events.

2.5.2.6.3 Deep Soil Mixing Method

Design and Construction

The DSM method of constructing a slurry cutoff wall uses a crane-supported set of two to four mixing augers (typically 36 inches in diameter) set side by side. These augers are drilled through the levee crown and foundation to the required depth (capable of a maximum depth of about 200 feet). As the augers are inserted and withdrawn, a cement-bentonite grout is injected through the augers and mixed with the native soil. An overlapping series of mixed columns is drilled to create a continuous seepage cutoff barrier (Figure 2-14).

To provide a wide enough working platform on the levee crown, the upper portion of some segments of the levee requires excavation with a paddle wheel scraper. Material is scraped and stockpiled at a nearby stockpile area. Dependent on the depth of the wall required, vertical clearance for the crane also may be needed. An excavator manipulates injector return spoils near the DSM rig, and transport trucks are used to haul spoils off site. A crane is used for in-place sampling of DSM material and also for loading bentonite into the batch plant hopper. A mobile batch plant (diesel-powered) is required near each DSM rig at the work area to prepare the cement-bentonite grout. The grout is transported to the DSM rig through flexible hoses. Each batch plant requires a pad of 50 by 100 feet. Hauling at the work area involves scraper runs along the levee to the staging area and cement and bentonite deliveries to the batch plant.

During DSM slurry wall construction, one DSM rig typically can construct 20 linear feet of DSM wall per eight-hour shift (for wall depths up to 135 feet).

The equipment and materials necessary to construct a DSM slurry wall are listed in Table 2-12. Post-construction, areas used for construction staging, the levee slopes, and any other disturbed areas are hydroseeded.

Table 2-12. Deep Soil Mixing Slurry Wall—Phases, Equipment, and Materials

Phases of Construction	Equipment	Materials
Site preparation (clearing, grubbing, and stripping)	Scraper	Cement
Work platform excavation	Excavator or track hoe	Bentonite
Deep soil mixing (DSM)	DSM crane	Hydroseed
Replacement of levee material	Bulldozer	Water (if no available domestic supply)
Finish grading	Front end loader	Aggregate base rock
Site restoration and demobilization	Haul truck	Miscellaneous construction support materials
	Paddle wheel scraper	Embankment fill material (if existing material is of poor quality)
	Water truck	
	Mobile batch plant	

Operation and Maintenance

Post-construction, the only permanent facility is the slurry cutoff wall. The only O&M activity would be observation for seepage during high-water events.

2.5.3 Flood Program Improvements for Slope Stability and Geometry

2.5.3.1 Flood Program (Slope Stability/Geometry): Slope Flattening

2.5.3.1.1 Objective

Slope flattening is a mechanical method to repair or reshape slopes that do not meet standards for geometry and stability (Figure 2-15). Levee slopes are typically subject to a standard of 3H:1V, but this may vary based on site-specific conditions and supporting engineering analysis. Slope flattening addresses the deficiency of slope stability and geometry.

2.5.3.1.2 Design and Construction

To begin slope flattening activities, the area is cleared, grubbed, and stripped to provide space for construction and reshaping of slopes. Additional embankment fill material may be necessary to achieve slope flattening. If so, bulldozers excavate and stockpile borrow material from a nearby permitted borrow site. Front-end loaders load haul trucks with the borrow material. The haul trucks transport the material to slope flattening site. Motor graders spread material evenly according to levee design plans, and sheepsfoot rollers compact the material. Water trucks distribute water over the material to ensure proper moisture for compaction.

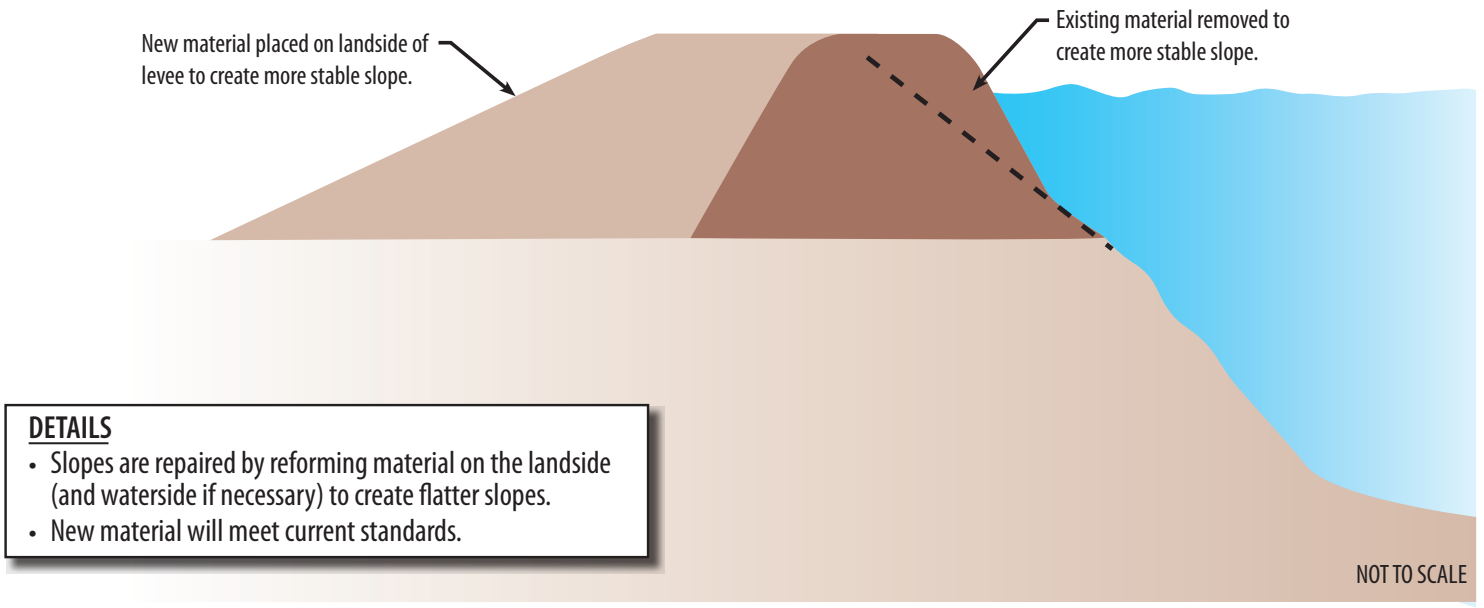


Figure 2-14
Deep Soil Mixing

Slope Flattening

Concept:

Flatter slopes are more stable and less susceptible to erosion.

00875.07 EIS (7-09)

Figure 2-15
Slope Flattening

To reshape a waterside slope, the existing crown of the levee is shifted farther landward and the waterside slope is trimmed and reshaped to a 3:1 slope. The shifted levee crown would be a minimum of 20 feet wide, with a 3:1 slope on the landward side. An access road made of aggregate base rock is constructed on the levee crown.

Equipment and materials necessary to implement slope flattening treatment are listed in Table 2-13. Post-construction, the construction staging areas, levee slopes, and any other disturbed areas would be hydroseeded.

Table 2-13. Slope Flattening—Phases, Equipment, and Materials

Phases of Construction	Equipment	Materials
Site preparation (clearing, grubbing, and stripping)	Scraper	Embankment fill material
Reshaping of slopes and placement of additional fill (if necessary)	Excavator or track hoe	Water
Finish grading	Bulldozer	Aggregate base rock
Site restoration and demobilization	Front end loader	Hydroseed
	Haul truck	
	Motor grader	
	Sheepsfoot roller	
	Water truck	

2.5.3.1.3 Operation and Maintenance

Post-construction, the only permanent facility is the improved levee. O&M would be the same as typical levees, as described under the in-place levee raise.

2.5.3.2 Flood Program (Slope Stability/Geometry): Stability Berm

2.5.3.2.1 Objective

A stability berm would be constructed against the landside slope of the existing levee with the purpose of supplying support as a buttress (Figure 2-16). The height of the stability berm is generally two-thirds the height of the levee; the structural needs of the levee determine the distance it extends along that reach. A stability berm addresses the deficiency of stability.

2.5.3.2.2 Design and Construction

To begin the construction of a stability berm, the site is cleared, grubbed, and stripped to provide space for construction and shaping of the berm. Embankment fill material necessary to construct the berm is excavated by a bulldozer from a nearby borrow site. Front-end loaders load haul trucks with the borrow material and the haul trucks transport the material to the stability berm site. Motor graders spread the material evenly according to design specifications, and a sheepsfoot roller compacts the material. Water trucks distribute water over the material to ensure proper moisture for compaction.

Equipment and materials necessary to construct a stability berm are listed in Table 2-14.

Table 2-14. Stability Berm—Phases, Equipment, and Materials

Phases of Construction	Equipment	Materials
Site preparation (clearing, grubbing, and stripping)	Scraper	Embankment fill material
Construction and shaping of stability berm	Excavator or track hoe	Water
Finish grading	Bulldozer	
Site restoration and demobilization	Front end loader	Hydroseed
	Haul truck	
	Motor grader	
	Sheepsfoot roller	
	Water truck	

2.5.3.2.3 Operation and Maintenance

The only post-construction permanent facility is the berm. O&M would be as described under the in-place levee raise.

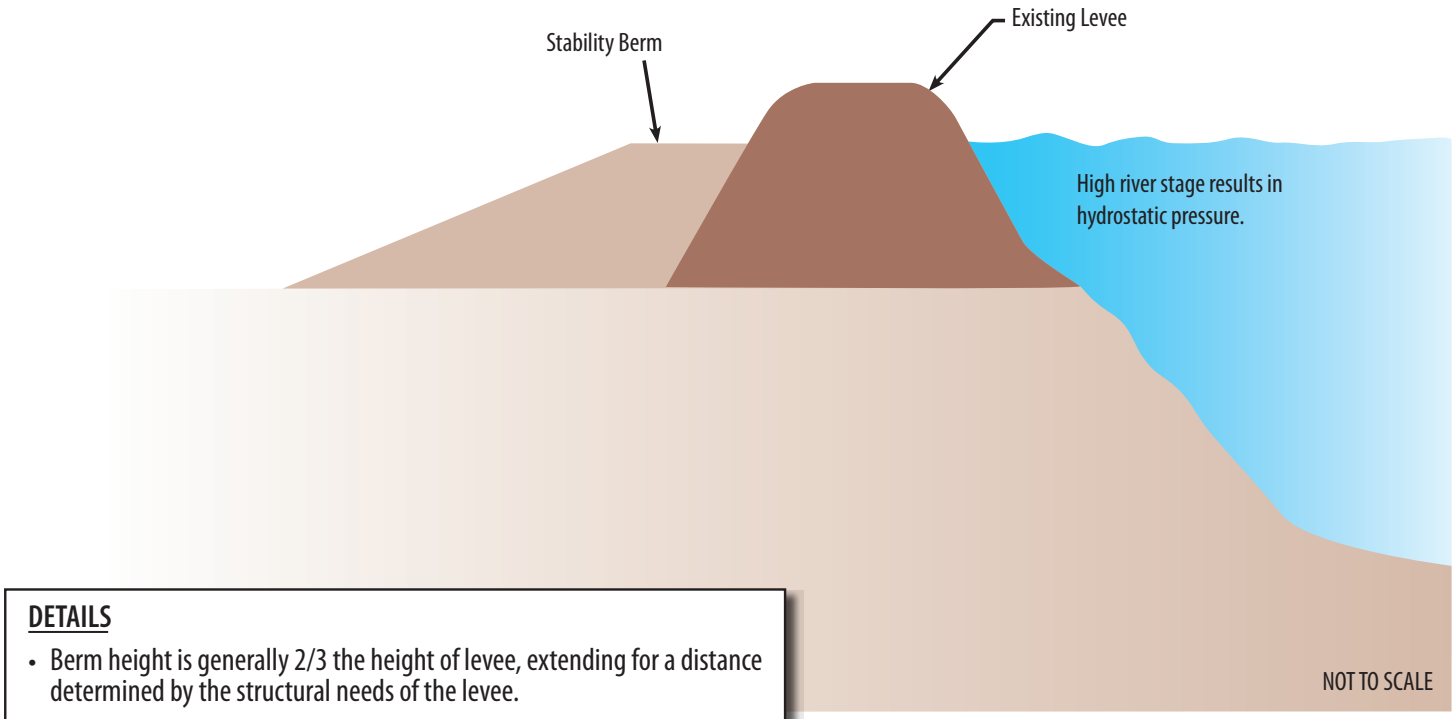
2.5.4 Flood Program Improvements for Erosion Control

2.5.4.1 Flood Program (Erosion Control): Rock Slope Protection

2.5.4.1.1 Objective

Portions of the levee slopes may be protected by the placement of rock slope protection. Rock is placed in a layer approximately 1 foot thick on the waterside of the levee to protect against erosional forces that threaten levee stability, such as wind, waves, and boat wake (Figure 2-17) Rock slope protection addresses the levee deficiency of erosion.

Wherever possible, the bank protection is designed both to control erosion and to maintain existing vegetation and instream woody material as much as possible. This can be accomplished by incorporating rock benches that serve as buffers against extreme toe scour and shear stress while providing space for planting riparian vegetation and creating a platform to support aquatic habitat features. Such features would be subject to and designed in compliance with USACE levee vegetation guidance.



2.5.4.1.2 Design and Construction

The placement of rock requires one excavator and one loader for each potential placement site. The loader brings the rock from a permitted source, within 25 miles of the project area, and dumps it within 100 feet of the levee. The excavator then moves the rock from the stockpile to the waterside of the levee. Soil may be placed in the interstitial spaces, followed by vegetation installation by hand. Equipment and materials necessary for rock slope protection are listed in Table 2-15.

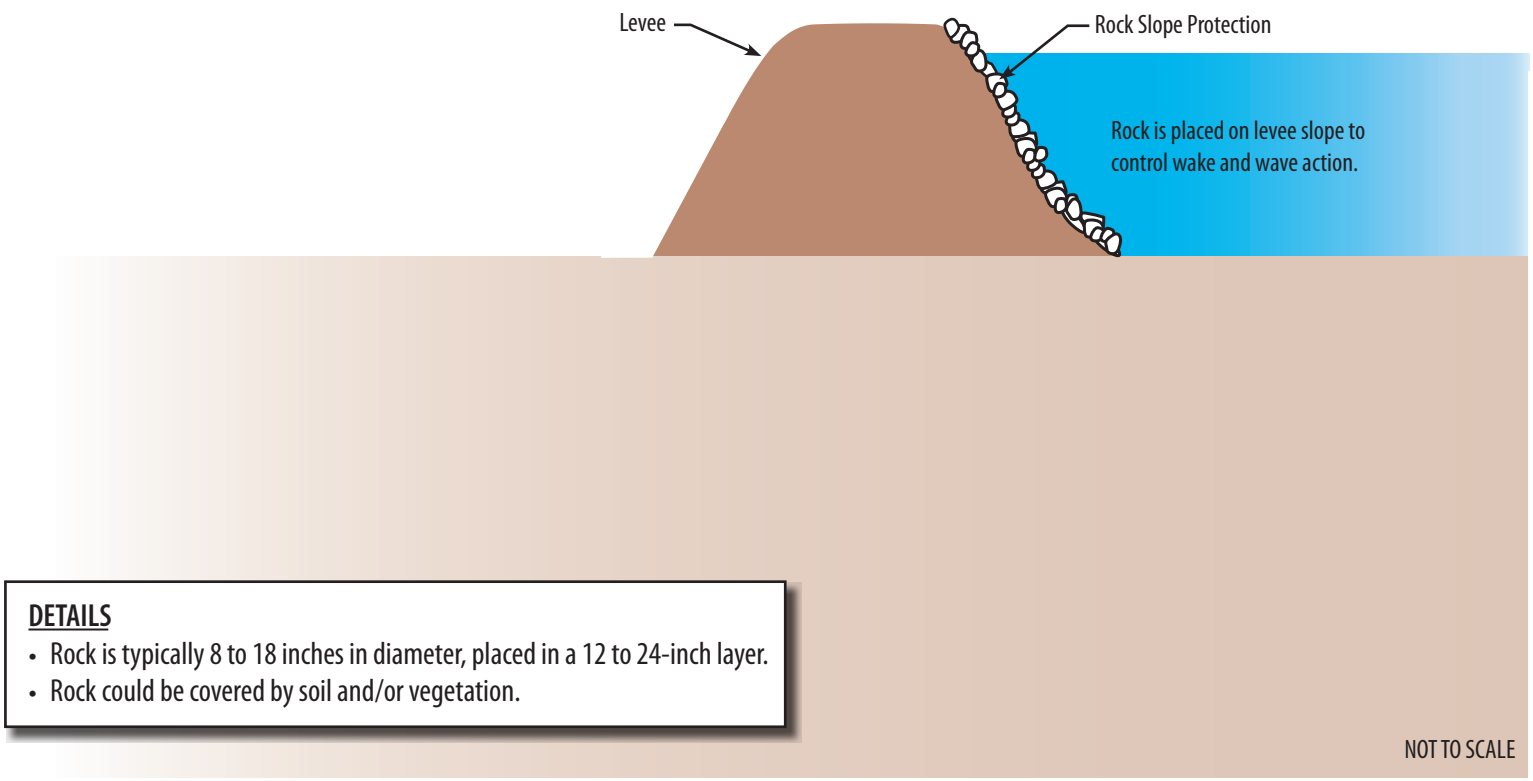
Stability Berm

Concept:

Provides additional support to levee to increase strength.

DETAILS

- Berm height is generally 2/3 the height of levee, extending for a distance determined by the structural needs of the levee.



00875.07 EIS (7-09)

Figure 2-16
Stability Berm

Rock Slope Protection

Concept:

Water-side erosion is prevented by placement of rock.

00875.07 EIS (7-09)

Figure 2-17
Rock Slope Protection

Table 2-15. Rock Slope Protection—Phases, Equipment, and Materials

Phases of Construction	Equipment	Materials
Site preparation (dependent on site conditions: clearing, grubbing, and stripping)	Scraper	Rock and soil (optional)
Rock placement	Excavator	Hydroseed
Biotechnical element installation	Hand tools	Geotextiles, coir logs, and stakes (optional)
Site restoration and demobilization	Haul truck	Pole cuttings, container stock, and transplanted vegetation (optional)

Post-construction, areas disturbed by the equipment or the rock stockpile area are hydroseeded.

2.5.4.1.3 Operation and Maintenance

The only permanent features post-construction would be the rock slope and vegetation and other biotechnical features. O&M for plantings may include irrigation, weeding, and monitoring during an establishment period.

2.5.5 Other Flood Program Improvements

2.5.5.1 Flood Program (Other): Setback Levee

2.5.5.1.1 Objective

A setback levee is an entirely new section of levee constructed at some distance behind the landside of the existing levee (Figure 2-18). The existing levee remains in place or is removed or breached, depending on conditions in that levee reach. The new section of levee is tied into the existing levee and then becomes the Federal project levee.

A setback levee can address the following deficiencies:

- inadequate levee height,
- through-seepage,
- slope stability and geometry,
- erosion, and
- non-compliant vegetation.

2.5.5.1.2 Design and Construction

The new levee section is constructed to meet current design standards, including height and slope requirements. To begin construction activities, the area required to construct the new levee is cleared, grubbed, and stripped. To construct the new section of levee, bulldozers excavate and stockpile borrow material from a nearby permitted borrow site. Front-end loaders load haul trucks with the borrow material. The haul trucks transport the material to the new levee site where motor graders spread it evenly. Sheepsfoot rollers compact the material, and water trucks distribute water over the material to ensure proper moisture for compaction. Levee slopes are graded to a 3:1 slope,

and a crown at least 20 feet wide is created. For the purpose of levee inspection, an aggregate base access road is constructed on the crown of the new levee.

If the material from the existing levee is of sufficient quality and not intended to remain in place, it may be excavated and used as fill for the new setback levee. If the existing levee is excavated, grading may be necessary within the setback area (between the new levee and the river) to ensure proper drainage.

Equipment and materials necessary to construct a setback levee are listed in Table 2-16. Post-construction, construction staging areas, levee slopes, and any other disturbed areas are hydroseeded.

Table 2-16. Setback Levee—Phases, Equipment, and Materials

Phases of Construction	Equipment	Materials
Site preparation (clearing, grubbing, and stripping)	Scraper	Embankment fill material
Embankment fill material placement	Excavator or track hoe	Water
Finish grading	Bulldozer	Aggregate base rock
Site restoration and demobilization	Front end loader	Hydroseed
	Haul truck	
	Motor grader	
	Sheepsfoot roller	
	Water truck	

2.5.5.1.3 Operations and Maintenance

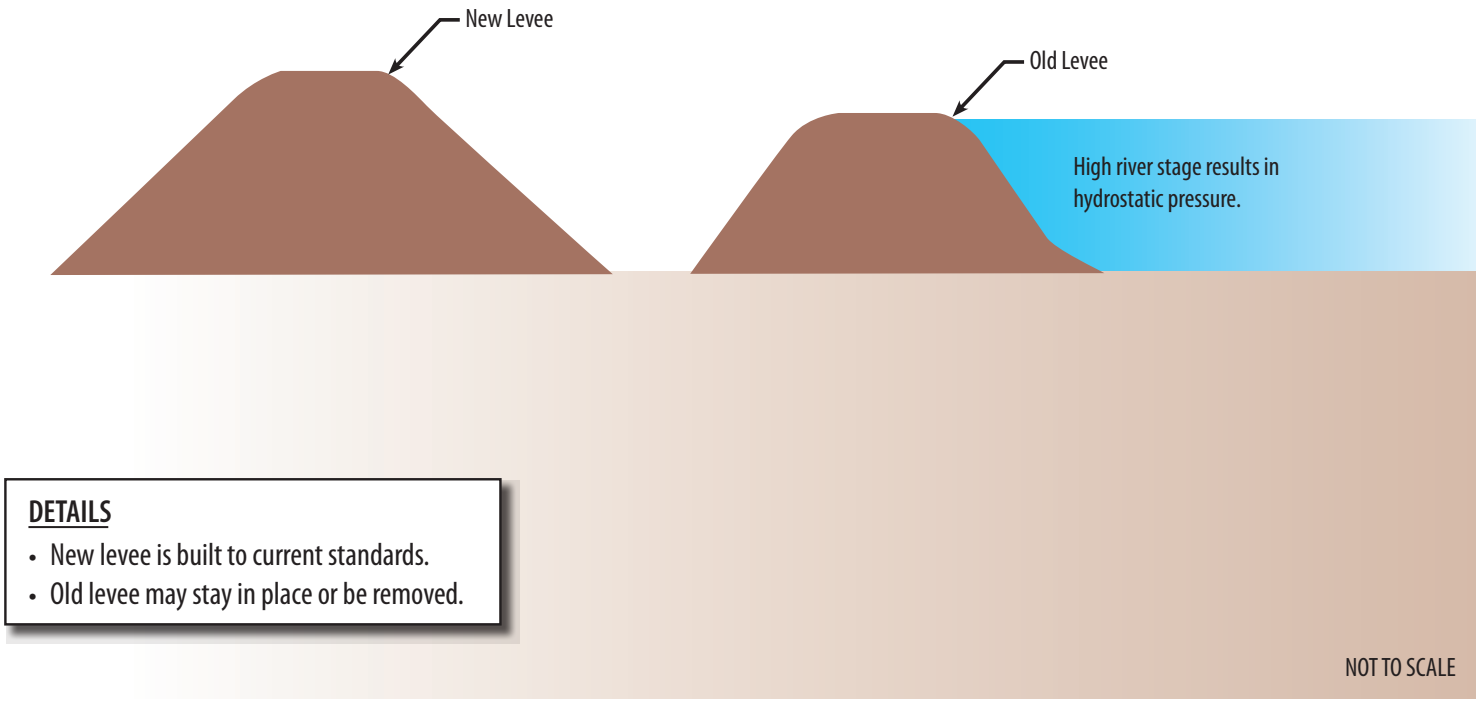
Post-construction, the only permanent facility is the improved levee. O&M would be the same as for a typical levee, described under in-place levee raise.

2.5.5.2 Flood Program (Other): Vegetation Removal

2.5.5.2.1 Objective

Levee standards for vegetation and encroachments may require woody plants to be removed from levees and maintenance easement areas. This improvement addresses the levee deficiency of non-compliant vegetation (Figure 2-19).

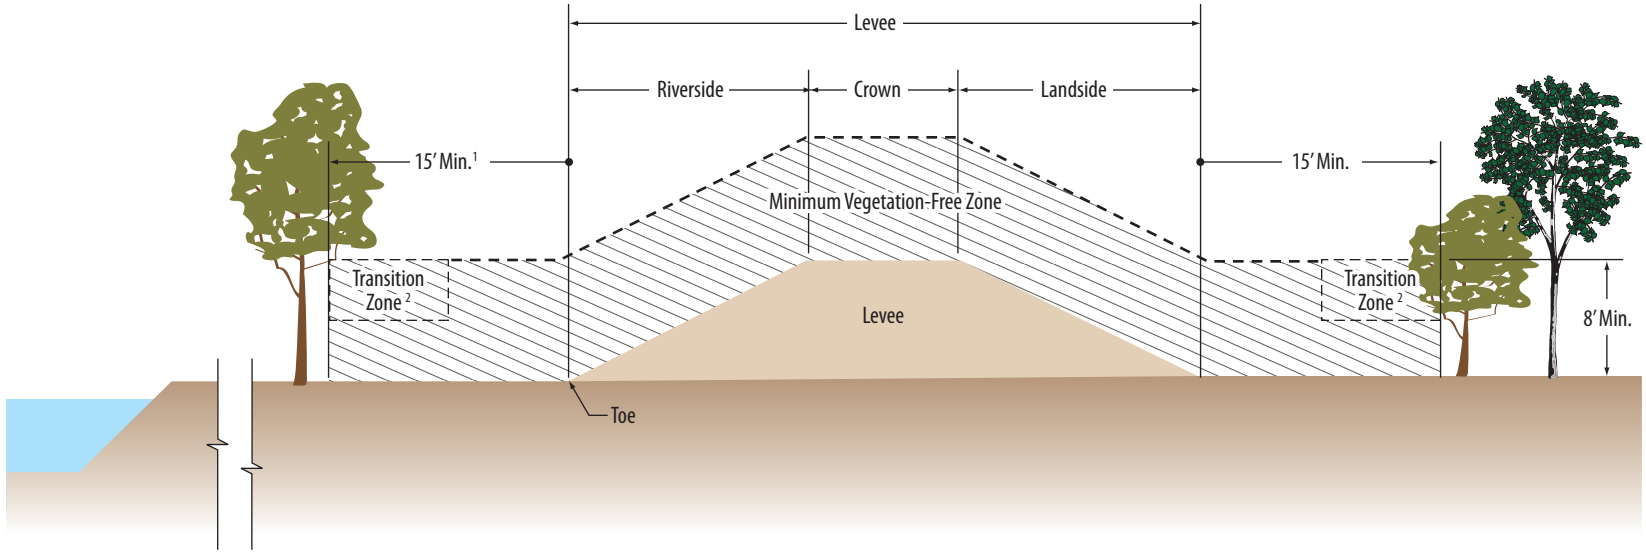
2.5.5.2.2 Design and Construction



As discussed in the section describing levee deficiencies, USACE has published new Guidelines for Landscape Planting and Vegetation Management at Levees, Floodwalls, Embankment Dams, and Appurtenant Structures for the control of vegetation on levees (ETL 1110-2-571 10 April 2009), hereafter referred to as USACE levee vegetation guidance. These guidelines recommend that a vegetation-free zone be established (Figure 2-19).

- The vegetation-free zone is a three-dimensional corridor surrounding all levees, floodwalls, embankment dams, and critical appurtenant structures in all flood damage reduction systems. The vegetation-free zone applies to all vegetation except perennial, non-irrigated grass. Grass species are permitted. The only grasses permitted are perennial grasses whose primary function

Setback Levee



Concept:

A new levee is built toward the landside of an existing levee where the existing levee is not readily repairable or where more flooding capacity is desired.

00875.07 EIS (7-09)

Figure 2-18
Setback Levee

Notes:
1. 15′ or distance to edge of normal water surface, if less
2. In this 4′x7′ transition zone, temporary obstruction by limbs and crown is allowed during development of new plantings, for up to 10 years

NOT TO SCALE

00875.07 EIS (7-09)

Figure 2-19
Vegetation-Free Zone
Defined in Engineering Technical Letter 1110-2-571 (2009)

is to reliably protect against erosion. The species selected for each project shall be appropriate to local climate, conditions, and surrounding or adjacent land uses. Preference should be given to native species.

- The primary purpose of a vegetation-free zone is to provide a reliable corridor of access to, or along, levees, floodwalls, embankment dams, and appurtenant structures. This corridor must be free of obstructions to assure adequate access by personnel and equipment for surveillance, inspection, maintenance, monitoring, and flood-fighting. In the case of flood-fighting, this access corridor must also provide the unobstructed space needed for the construction of temporary flood-control structures. Access is typically by four-wheel-drive vehicle, but for some purposes, such as maintenance and flood-fighting, access is required for larger equipment, such as tractors, bulldozers, dump trucks and helicopters. Accessibility is essential to the reliability of flood damage reduction systems.
- The vegetation-free zone must be wide enough and tall enough to accommodate all likely access requirements.
- The minimum width of the corridor shall be the width of the levee, floodwall, or embankment dam, including all critical appurtenant structures, plus 15 feet on each side, measured from the outer edge of the outermost critical structure. In the case of a landside planting berm, the 15 feet is measured from the point at which the top surface of the planting berm meets the levee section. The minimum height of the corridor shall be 8 feet from any point on the ground.
- No vegetation, other than approved grasses, may penetrate the vegetation-free zone, with two exceptions:
    - Tree trunks are measured to their centerline, so one half of the tree trunk may be within the vegetation-free zone.
    - Newly planted trees, whose crowns can be expected to grow, or be pruned, clear of the vegetation free zone within 10 years may be within the vegetation-free zone. (U.S. Army Corps of Engineers 2009.)

In accordance with the USACE levee vegetation guidance, WSAFCA will submit a detailed removal plan to the local USACE District Levee Safety Officer for review and comment prior to removal of vegetation. Methods for removing non-compliant vegetation are identified below.

- By excavation, remove the trunk (or stem), stump, rootball, and all roots greater then 0.5 inch in diameter—all such roots in, or within 15 feet of, the flood damage reduction structure will be completely removed.
- Assure that the resulting void is free of organic debris.
- Cut poles to salvage propagation materials for replanting, such as willows and cottonwoods.
- Conduct hand clearing using chainsaws and trimmers.
- Conduct mass clearing using bulldozers.

2.5.5.2.3 Operations and Maintenance

Ongoing vegetation maintenance would include mowing, herbicide application, and hand clearing and mass clearing methods discussed above.

2.6 Program-Level Alternatives for Recreation

The City as a member agency of WSAFCA is proposing recreation and non-motorized transport improvements that are compatible with flood improvement actions to meet recreation needs. The West Sacramento Parks Master Plan (Parks Master Plan) has identified several key recreation opportunities for the city that would enable its population and others to enjoy the resources provided by the Sacramento River and other waterways. Some of those opportunities use corridors along waterways such as the Sacramento River, DWSC, turning basin, barge canal, and Yolo and Sacramento Bypasses. These corridors are an opportunity for development of pedestrian and non-motorized linkages that can be used for transportation as well as recreation (Parks Master Plan 2003; Bicycle and Pedestrian Path Master Plan 1995) and would be analyzed along with levee improvements as part of the WSLIP.

Recreation corridors are proposed throughout the city along the water edges. The recreation corridors are designed with multi-purpose trails as the primary features. These trails can be used for recreation and as alternative transportation routes. They are for walking, jogging, biking, and, where appropriate, equestrian use. They also help tie the community together by linking people with destinations such as parks, recreation facilities, schools, churches, and the workplace. In addition to the trail, recreation corridors may include landscaping, benches, small picnic areas, small play areas, and other recreation features. These features may be further developed where the recreation corridor forms the edge of a park. Formalized access to the river and other waterways would be incorporated into the design of waterside recreation corridors at logical locations (Figure2-20) (Parks Master Plan 2003; Bicycle and Pedestrian Path Master Plan 1995).

Recreation improvements have been described below at the program level on the simple basis of trails, parks, developed water access, and special projects. Reach- and feature-specific information is described where available, typically listed on a geographic basis moving clockwise around the city. These descriptions are substantially based on the following City guidance documents:

- City of West Sacramento Parks Master Plan (Parks Master Plan),
- Sacramento Riverfront Master Plan (SRMP),
- Bicycle and Pedestrian Path Master Plan,
- Washington Specific Plan,
- Triangle Specific Plan(now known as Bridge District) , and
- Southport Planning and Design Criteria.

2.6.1.1 Recreation Program: Trails

2.6.1.1.1 Objective

As introduced above, trails provide recreation and alternative transportation links for pedestrians, cyclists, and, where appropriate, equestrians. Patrol roads on levee crowns provide an opportunity for use shared by flood management and recreation, doubling as publicly accessible trails. Many levees already are used this way and could be developed in coordination with flood improvements for safe, managed access.

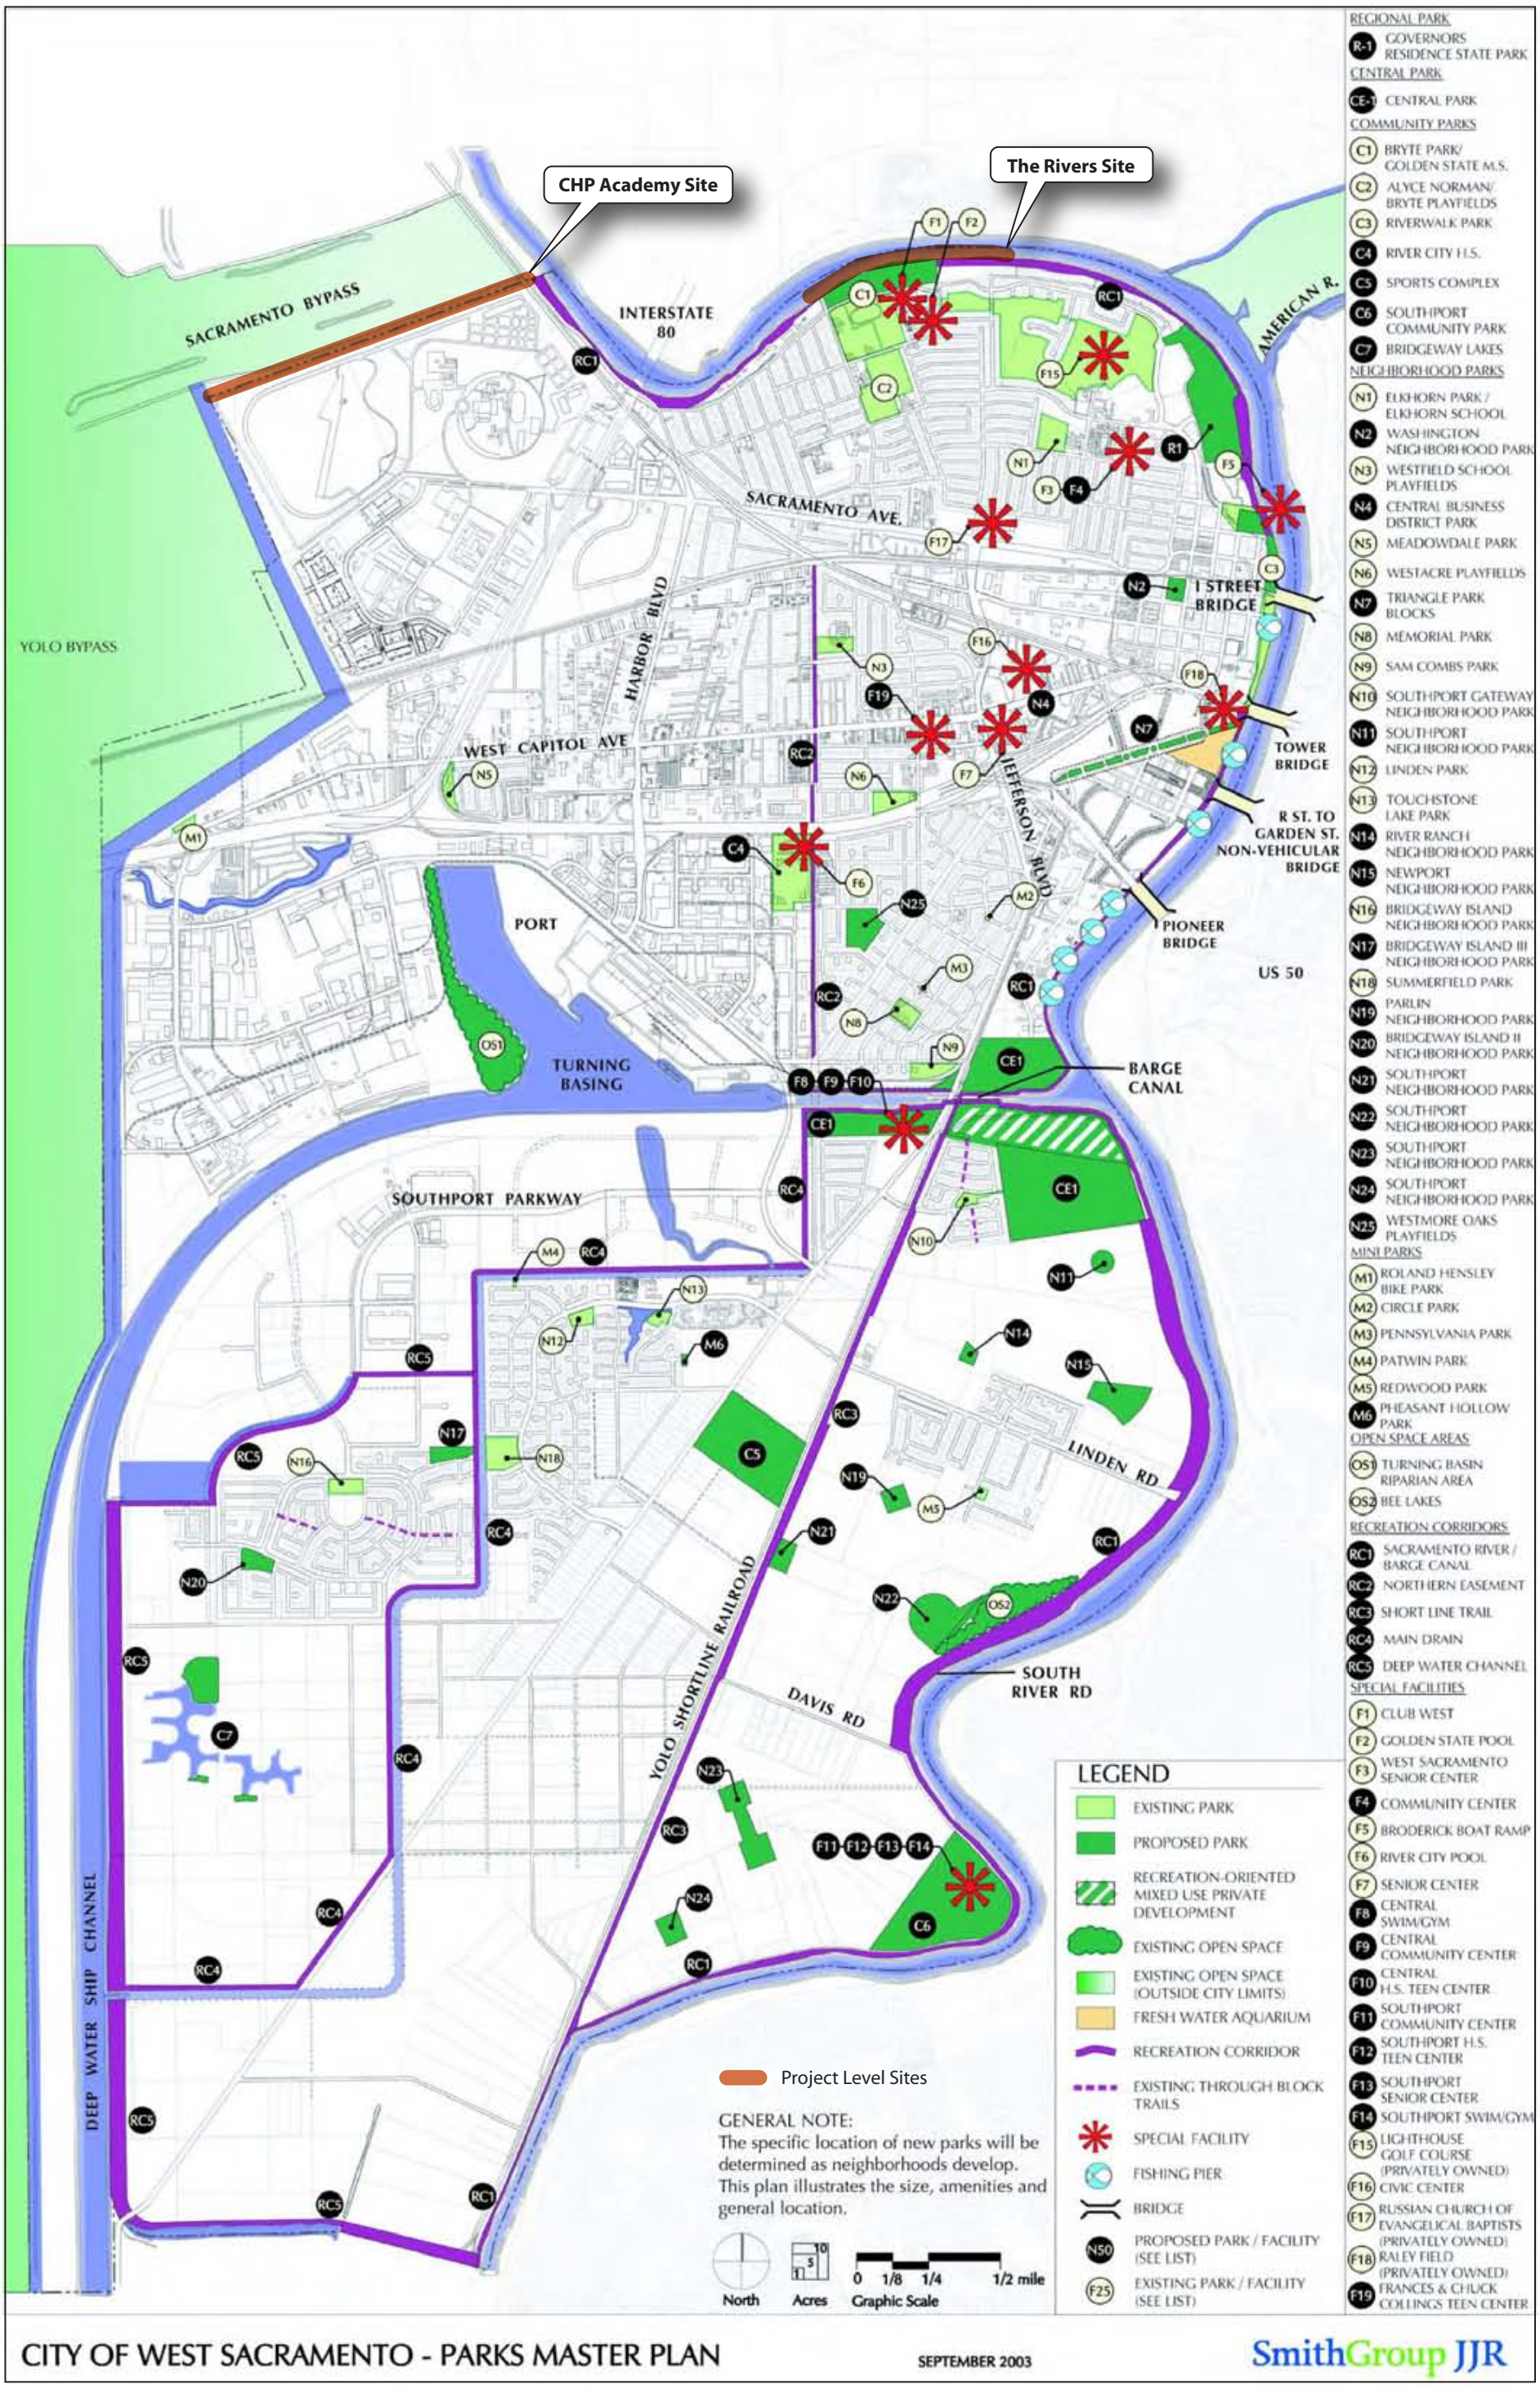


Figure 2-20
Recreation Corridors

2.6.1.1.2 Design and Construction

The development of recreation trails within reclamation district easements is subject to approval by the local reclamation district and CVFPB and generally requires submittal of plans for proposed work with an application to CVFPB for a permit. Recreation trails on levees, therefore, would be consistent with the Standards for Encroachments (April 1976), and Policy on Bicycle Trails on Levees, adopted June 21, 1991, as subject to CVFPB approval. In almost all cases, trails would be paved to ensure accessibility for a broad range of use and user needs.

The following information is a summary based on CVFPB requirements and would be adhered to under the WSLIP.

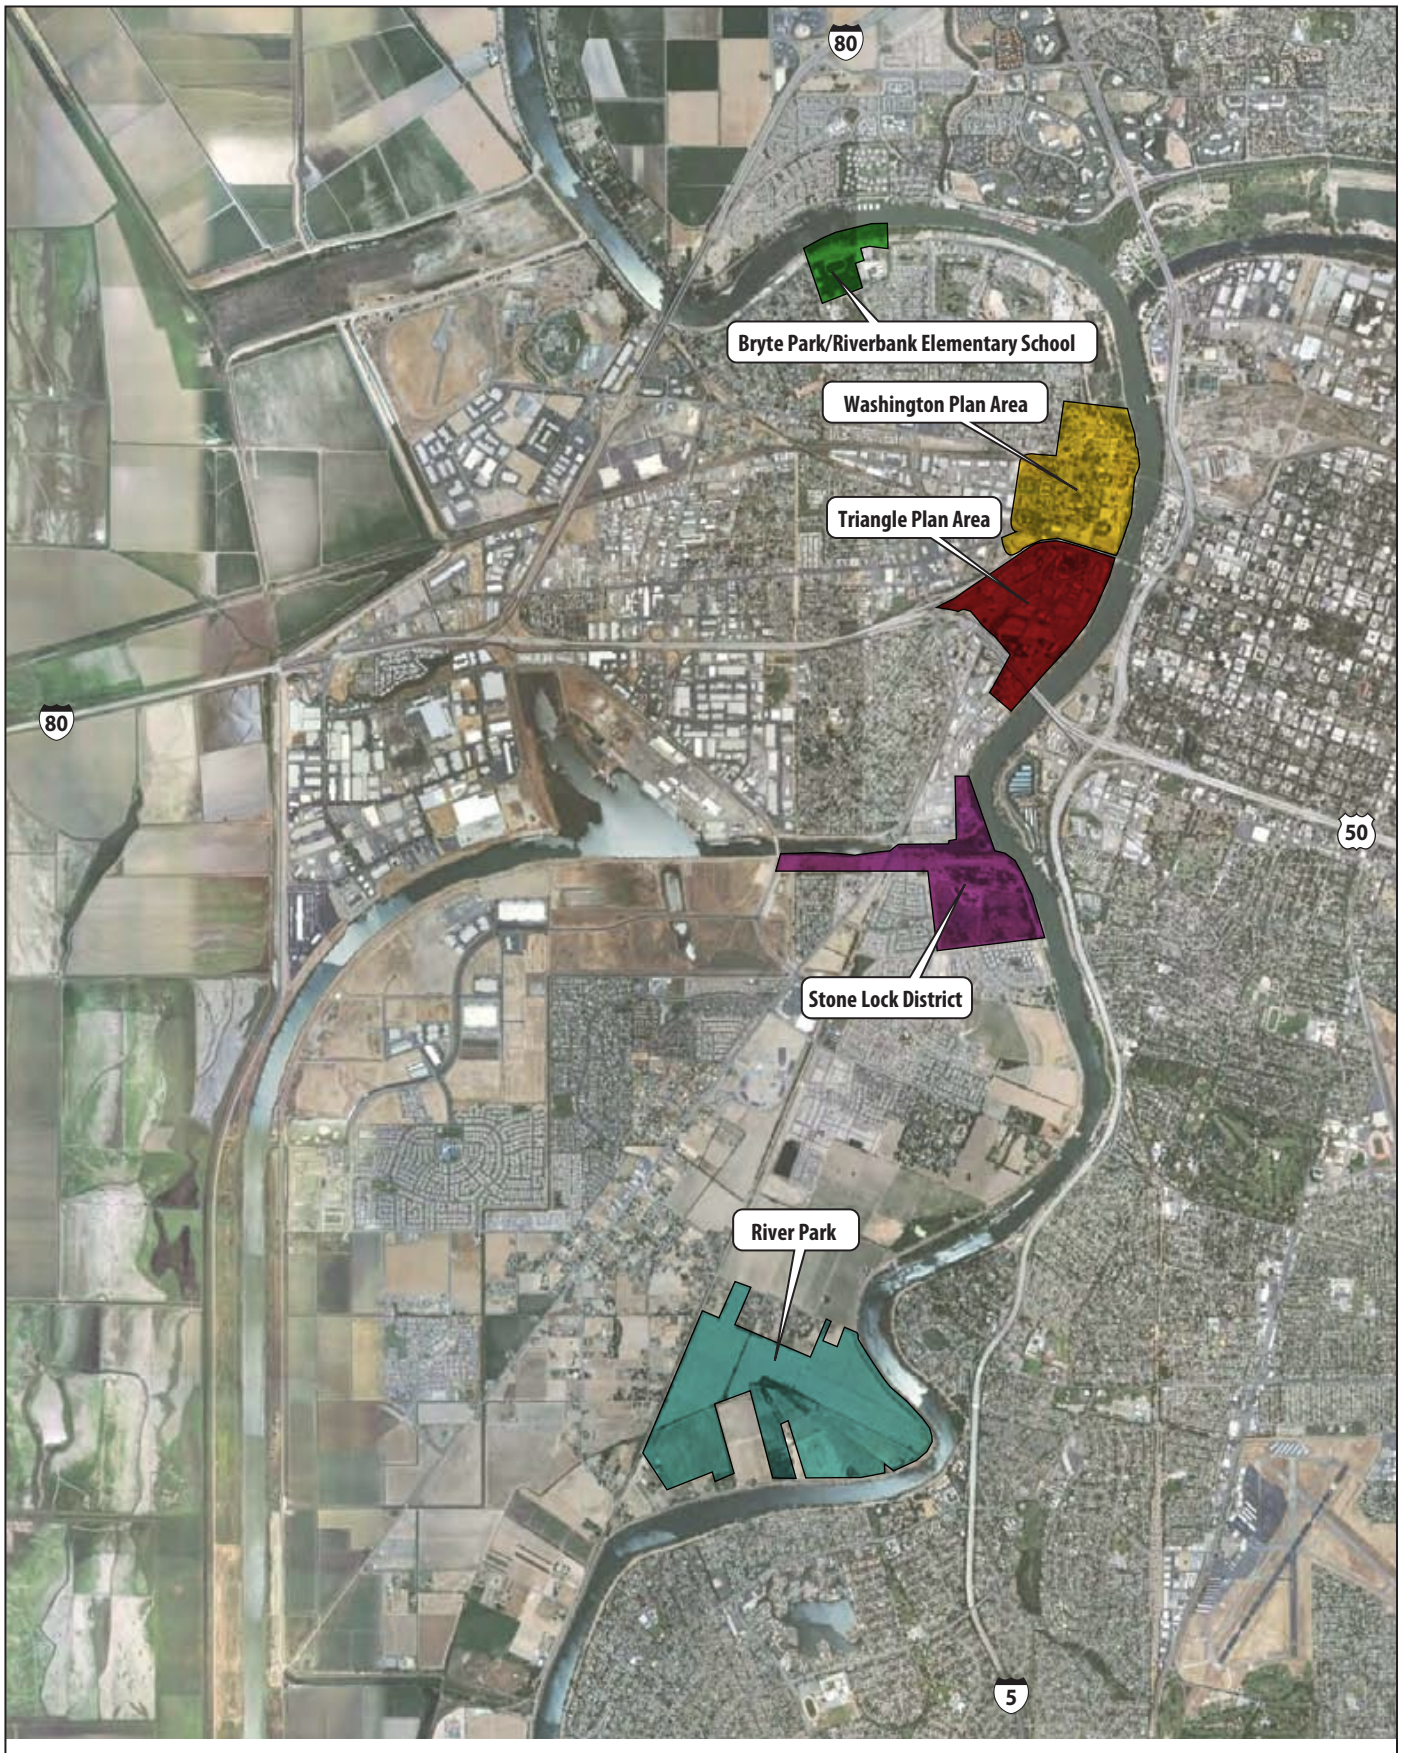
- Paved trails for bicycles would be designed in accordance with design standards for state highways and county roads. Trails for bicycles would have a minimum width of 12 feet and a minimum shoulder width of 2 feet on each side of the pavement and would consist of a minimum of 6 inches of aggregate base beneath 2 inches of asphalt concrete pavement or equivalent. Trails on the levee slopes are not permitted, except for access ramps. Trails and access ramps would slope away from the levee crown.
- All patrol roads must be maintained for use by the reclamation district. Unauthorized vehicular access would be prevented by a physical barrier that is removable to allow access for maintenance, inspection, and emergency vehicles.
- Barriers would be secured by locks, and keys provided to DWR and the local flood control maintaining agency.
- Ramps must be constructed of imported material. Cuts into and reshaping of the levee, in any manner, are expressly prohibited.
- No excavation or cuts are allowed on the Sacramento River levees from November 1 to April 15.
- Removal of any borrow material from levees and deposit of embankment, spoil, and/or waste materials requires a permit.
- The City would adopt and enforce use restrictions, subject to CVFPB's approval and, as a minimum, would restrict public access to designated areas and prohibit equestrian and vehicular access.
- Permanent signs would be provided at all trail access points to levees and at periodic intervals along trails located on levees identifying the trail as a "levee maintenance road" and instructing users to "watch for patrolling vehicles."

In addition to the trail itself, other amenities on trail corridors may be benches, directional and interpretive signage, access gates, emergency call boxes, lighting, and refuse receptacles. All amenities would be subject to approval by the reclamation district and CVFPB and permits as required from the City. Independent environmental documentation may exist or would be developed for some of these projects as necessary. Specific proposed trail projects known at this time are noted below.

- **Recreation Corridor 1—Sacramento River/Barge Canal.** The Parks Master Plan provides for a recreation corridor along the entire length of the Sacramento River. This corridor is approximately 13.1 miles long and occupies approximately 192 acres. It will provide a continuous recreation corridor along the entire length of the Sacramento River within the city limits. A portion of this corridor has already been constructed along the urban waterfront, and is

commonly referred to as the River Walk Park, often shortened to just Riverwalk or Promenade. In the future, this path will extend from the water's edge to include the publicly owned right-of-way for the existing sections of Riverwalk, the future extension of Riverwalk from the Tower Bridge south to the Pioneer Bridge, and interior paths in other areas along the Sacramento Riverfront. It will link the city's community parks, businesses, and residential areas. In the southern portion of the city, the path will use the South River Road alignment once this road is replaced by a new off-levee arterial. Construction of a bicycle and pedestrian-friendly bridge crossing is proposed at the extension of River Road over the River Road Bridge to maintain the continuity of the corridor. The design criteria for the Recreation Corridor are outlined in the Southport Planning and Design Criteria.

- **Triangle Plan Area (Bridge District).** The Triangle Plan Area is approximately 188 acres bounded by State Route (SR) 275 on the north and west, Business 80 on the south, and the Sacramento River on the east (Figure 2-21). The waterfront of the Triangle Plan Area (now known as Bridge District) includes a promenade that will be a minimum of 20 feet wide to accommodate a foot path and bicycle path, with an additional 6 feet of furnishing zone (for park benches and other features). The elevation of the promenade will be 35.5 feet, and it will be sloped away from the river bank to allow water runoff to be collected by the City stormwater system. The promenade will run the entire length of the Triangle Plan Area. See other Triangle Plan Area descriptions under Riverside Parks and Developed Water Access.
- **Recreation Corridor 5—Deep Water Ship Channel.** The Parks Master Plan provides for a recreation corridor along the DWSC. This recreation corridor is approximately 5.3 miles long and will occupy approximately 123 acres. This corridor will tie into Recreation Corridor 1 at the southern city limit forming a loop system. It also will connect to Recreation Corridor 4, creating an additional loop. Approximately 2.25 miles of this corridor are along the DWSC and may be constructed part of the WSLIP.
- **Sacramento Bypass Corridor.** This corridor is approximately 1.2 miles long and will occupy 2.4 acres. It will tie into Recreation Corridor 1 at the northern city limits.
- **Yolo Bypass Corridor.** This corridor is approximately 3.8 miles long and will occupy 7.3 acres. It will tie into the Sacramento Bypass corridor.
- **South Cross Levee.** This corridor is approximately 1.2 miles long and will occupy 2.3 acres. It will tie into Recreation Corridor 1 and Recreation Corridor 5.



2.6.1.1.3 Operations and Maintenance

O&M activities for paved trails may include annual mechanical sweeping and cleaning, annual replacement and smoothing of the shoulder, annual inspection for pavement integrity, crack filling every several years, and cleaning and repairing signage and access controls. Other O&M for paved trails and O&M for unpaved trails would be the same as described as for typical levee practices under in-place levee raise.

2.6.1.2 Recreation Program: Riverside Parks

2.6.1.2.1 Objective

The water corridors in and around West Sacramento provide opportunities for fishing, picnicking, wildlife viewing, outdoor education, and other passive recreation. Interspersed along water

00875.07 001 EIR/EIS (6-09)

Figure 2-21
Riverside Parks Location Map

corridors are future parks in the planning process or existing parks proposed for improvement. Riverside parks, in both established and new neighborhoods, are a key element in meeting recreation demands within the city.

2.6.1.2.2 Design and Construction

Riverside parks, which may occur on the landside or waterside of the levee, would be subject and adhere to reclamation district and CVFPB standards for encroachments, consistent with trails described above. Park amenities may include the following elements:

- turf, plantings, and other managed vegetation;
- tables, benches, and similar furnishings;
- water fountains;
- access controls such as gates, bollards, and fencing;
- directional and interpretive signage;
- paving for pedestrian circulation and parking areas;
- paved or unpaved landings or benches;
- lighting and call boxes;
- non-habitable structures such as restrooms, gazebos, kiosks, and overlooks; and
- play and fitness structures.

All amenities would be subject to approval by the reclamation district and CVFPB, and permits as required from the City. Independent environmental documentation may exist or would be developed for some of these projects as necessary. Specific riverside park projects known at this time are noted below (Figure 2-21).

- **Bryte Park/Riverbank Elementary School.** This existing park lies in the northernmost portion of the Sacramento River North Levee. Proposed expansion plans include adding 23 acres to this park that would connect it to the Sacramento River and provide formalized public access with pathways, picnic areas, and connection to the riverfront recreation corridor.
- **Washington Plan Area.** The Washington Plan Area is a 194-acre urban area near the northeast corner of the city of West Sacramento. It is bounded by Tower Bridge Gateway on the south, the Sacramento River on the east, A Street on the north, and portions of Sixth and Eighth Streets on the west. Waterfront features in this planning area include the Broderick Boat Launch north of the I Street Bridge. The Riverwalk Promenade extends along the full length of the riverfront park. The Broderick Boat Launch and Raley's boat dock are at the water's edge to serve private boating enthusiasts and potential water taxi service. Enhancements to these existing facilities may include terraced landscape areas, terraced steps, and a riparian habitat zone.
- **Triangle Plan Area.** A riverfront park along the length of the Bridge District will provide views of the Sacramento River and the downtown Sacramento skyline from the Riverwalk Promenade. Waterfront access will be provided by a variety of stairways, on-water walkways and foot trails at select locations. The riverfront park will be designed to incorporate riparian habitat zones or terraced overlooks. The riparian habitat zones will contribute another dimension to the waterfront experience and enhance wildlife habitat in the area. Pedestrian trails will be the only access below the levee crown. Pedestrian trails in these areas will be a maximum of 6 feet wide

and made of asphalt or concrete. Trail locations will not conflict with sensitive habitat areas (Triangle Specific Plan). Terraced walkways and patio areas will have large-canopy tree plantings such as sycamores and oaks, and pedestrian-only access trails. The terraced areas are intended for informal gathering spaces with views across the Sacramento River. In the central portion of the waterfront, a grand plaza will offer a venue for riverfront performances and events and an inviting waterfront park during times when no events are in progress. To the south of the plaza will be a series of pathways, stairs, and terraced areas along the river's edge for informal access. A U-shaped floating walkway will provide water-level access from the levee top. Two or three piers are also planned to provide views of the river from the levee crown elevation. On the river embankment in the northern and southern reaches of the Triangle, the SRMP envisions the reestablishment of the river edge as a riparian habitat zone for both terrestrial and aquatic species. . See Triangle Plan Area descriptions under Trails and Developed Water Access.

- **Stone Lock District.** The Stone Lock District comprises about 220 acres of publicly owned land along the Port South Levee between Lake Washington and the Sacramento River, the Port North Levee from the Stone Lock to the Sacramento River confluence, and the Sacramento River North Levee and Sacramento River South Levee near the confluence of the Sacramento River with the barge canal. The City's Parks Master Plan and Riverfront Master Plan propose the creation of public recreation areas and open spaces along the District waterfronts as community and neighborhood parks for the City and amenities for the Sacramento region. These waterfronts occupy the southernmost end of the Sacramento North Levee, along the barge canal on the Port North and Port South Levees, and in the confluence area on the Sacramento River South Levee. The primary recreation element in the District would be Recreation Corridor 1, described above. Other recreation and open space uses along the District waterfronts are described below.

  The portion of the District along the Sacramento River North Levee and westernmost portion of the Port North Levee is called Stone Lock Bluff Community Park in the SRMP. Waterfront features within this area include a marina to take advantage of the inlet created by the barge canal and provide boat mooring off of the main river channel. This facility is envisioned as an "eco-marina" that would provide access to docks at specified locations between improved and protected riparian habitat zones. In addition to a marina, one or more riverfront restaurants or other commercial uses could be developed in this area, either floating or at the edge of the bluff to maximize views of the river. A small outdoor park completes the mixed use program at the bluff by providing public access to views of and across the river, as well as an outdoor gathering/event area to complement adjacent commercial development.

  The barge canal waterfront along the Port South Levee is intended for a range of features that provide public access to the water and support active and passive recreation. The uses envisioned for this location include a rowing and boating center with on-water dock and landside facilities (at the east end of the canal), viewing and fishing piers (at intervals along the canal), a neighborhood park (along the western portion of the canal) and a continuous bicyclist and pedestrian path along the bank top between Jefferson and Lake Washington Boulevards.

  The bank of the Port South Levee from Jefferson Boulevard to the confluence with the Sacramento River is intended for both recreational and cultural facilities, including a stepped amphitheater on the bank (east of the new roadway bridge) and a large waterfront gathering/community festival venue on terraces overlooking the river confluence. The iconic performance venue and primary civic gathering space will be connected by a formal pedestrian promenade at the levee top.

Southward from the barge canal along the Sacramento River South Levee, waterside recreation facilities include on-levee and lower bank trails, river-level landings for access to the water, elevated viewing piers and picnic areas. These waterside recreation features will be connected by bicyclist and pedestrian paths along the waterfront and accessible at occasional parking areas on or near the levee. (Shpak pers. comm.)

- **River Park.** Renamed as River Park by the surrounding residential development, Southport Community Park is approximately 40 acres in the southeastern Southport community along the Sacramento River South Levee. This riverfront community park will be connected with Recreation Corridor 1, described above. The landside park will include a community center and pool, tennis club, playground, and disc golf course.

2.6.1.2.3 Operations and Maintenance

O&M activities for parks may include annual inspection and restoration, weekly cleaning, weekly vegetation management, and other activities typical for municipal park facilities.

2.6.1.3 Recreation Program: Developed Water Access

2.6.1.3.1 Objective

The city's waterways not only provide an opportunity for passive recreation and enjoying the corridor as a visual amenity but also are attractive for direct physical access for water-based activities. Developed access features provide the infrastructure for safe, managed use.

2.6.1.3.2 Design and Construction

Water access amenities are subject to stringent standards and review in order to ensure flood management objectives and performance are not compromised. Developed access within reclamation district easements is subject to approval by the local reclamation district and CVFPB and generally requires submittal of plans for proposed work with an application to CVFPB for a permit. Developed access within floodways, therefore, would be consistent with the Standards for Encroachments (April 1976), and Policy on Bicycle Trails on Levees, adopted June 21, 1991, as subject to CVFPB approval.

The following information is a summary based on CVFPB requirements and would be adhered to under the WSLIP.

Steps on Levees

- Access steps on the riverside or landside of the levee must be constructed of concrete, rock, or brick embedded in concrete, and must be built flush with the levee slope. Cuts in the slope would not exceed 12 inches in depth. Steps would be a maximum of 4 feet in width and would not extend above the levee crown.
- Existing stone protection, if disturbed, would be restored to original condition.
- Wooden steps may be permitted at locations where the landslide slope of the levee is landscaped under permit and maintained by the owner. Wooden steps must be constructed on, not in, the levee slope.

- A ramp, 6 inches wide, should be constructed adjacent to the steps to facilitate transport of bicycles along the steps.

Walkways on Levees

- Concrete and wooden walkways with handrails are permitted on both sides of levees if they do not unduly interfere with levee maintenance.
- The bottom of the walkway stringers on the riverside slope must be 2 feet above the design floodplain elevation.
- Existing stone protection, if disturbed, would be restored to its original condition. Handrails may not be constructed on the levee crown.
- On a levee with a crown width less than 14 feet, handrails must be a minimum of 8 feet from the levee centerline. Walkway supports must be constructed to minimize the possibility of catching drift.

Other access amenities may include pedestrian pathways and ramps, gangways, docks, piers, boat launch ramps, site furnishings, directional and interpretive signage, access gates, emergency call boxes, lighting, and refuse receptacles. All amenities would be subject to approval by the reclamation district and CVFPB and permits as required from the City. Independent environmental documentation may exist or will be developed for some of these projects as necessary. Specific developed water access projects known at this time are noted below.

- **Washington Plan Area.** See description in section above (2.6.1.2.2).
- **Triangle Plan Area (Bridge District).** The Bridge District includes several waterfront features that are intended to function as the front yard to the urban core of the city. Streets and open spaces in the area will be oriented to encourage free movement to, from, and along the waterfront so that it may be enjoyed to the fullest (Triangle Specific Plan). The Riverwalk Promenade will run the full length of the waterfront in the Triangle Plan Area. As stated above under riverside parks, a grand plaza is proposed. The SRMP proposes two types of pier structures for the promenade. One is a floating visitor boat dock that would provide visitor access and the second is a fixed fishing platform. The floating dock would have hinged ramping structures to provide legally conforming access from the promenade to the dock, and fishing would be allowed on the downstream portion of the dock. The floating dock also would accommodate attractions such as a pool barge or floating restaurant attached to the inside (shore edge) of the dock structure. The other type of pier structure would be high-level overlook and fishing piers. These structures would extend from the promenade level out over the embankment to the water's edge, using a cantilever structure to the extent feasible in order to minimize piers in the embankment or in the water (SRMP). See other Triangle Plan Area descriptions under Trails and Riverside Parks.
- **Stone Lock District.** See description in section above (2.6.1.2.2).
- **River Park.** The community park improvements will include an in-channel marina in the same location as the defined marina on the site. The facility will consist of open boat slips, a floating administration/restaurant building, and automobile parking (Figure 2-22).

2.6.1.3.3 Operations and Maintenance

O&M activities for developed water access may include annual inspection and restoration, weekly cleaning, weekly vegetation management, and other activities typical for municipal park facilities.

2.6.1.4 Recreation Program: Special Projects

2.6.1.4.1 Objective

The city's waterways provide a unique setting for special project venues. The City plans to partner with other public and private entities to facilitate development of cultural, recreation, education, and entertainment facilities along the Sacramento River and other waterways.

2.6.1.4.2 Design and Construction

Special projects represent a more intensive level of development and use and would be subject to special permits and project-specific conditions. Improvements for special projects are location-specific and would be developed on a case-by-case basis, each likely necessitating independent environmental documentation and permitting. One such project at this time is relocation of the California Indian Museum from Sutter's Fort in Sacramento to a parcel on the Sacramento River in West Sacramento, described below.

- **California Indian Heritage Center.** On June 18, 2008, the City approved an agreement to contribute a 43-acre parcel on the riverfront to California State Parks for use as the new California Indian Heritage Center. The center will replace the California Indian Museum currently located in a small building at Sutter's Fort State Historic Park in Sacramento. This entire property is located on the waterside of the existing levee. California State Parks is developing a General Plan for the facility, which is planned to include a library, archives, tribal treasures exhibit space, resident artist space, offices, classrooms, a café, museum store, amphitheatre and event space, indigenous gardens, trails, public access to the Sacramento River, and parking. Though none of these elements is proposed for construction as part of the WSLIP, the City's agreement with California State Parks stipulates that WSAFCA may use some of the property for WSLIP habitat mitigation.

2.6.1.4.3 Operations and Maintenance

O&M activities for special projects are not known at this time but would entail intensive daily management, typical for public institutions with high visitor use.

2.7 Summary of Program Improvements by Reach

Based and building on the information presented earlier in this chapter, Table 2-17 summarizes the potential flood and recreation improvements on a reach-by-reach basis.

Table 2-17. Summary of Program Improvements by Reach

Improvement Group	Improvement	Reach: Sacramento River North Levee	Sacramento River South Levee	Port North Levee	Port South Levee	South Cross Levee	DWSC West Levee	DWSC East Levee	Yolo Bypass Levee	Sacramento Bypass Levee

2.8 Project-Level Alternatives

2.8.1 Introduction and Project Phasing

Up to this point, this chapter has described program-level improvements for flood management and recreation. This section summarizes project-level improvements in the form of two EIPs. These EIPs are being analyzed in a parallel process with the WSLIP to address critical areas where the levee deficiency is well-defined and the most suitable treatments are known, applying the project-level criteria presented earlier in this chapter.

Future EIPs may be proposed and analyzed based on the project-level screening criteria in Section 2.2.2.3. In addition to the project-level screening criteria in Section 2.2.2.3, other factors for

Central Parkway: An illustrative plan

(Note: This illustrative plan is conceptual only, and is subject to refinement by Richland Planned Communities Inc. based on consultation with the City of West Sacramento Parks and Recreation Department.)

Figure 2-22
Proposed River Park

project selection may be considered such as managing flood risk between the northern and southern basins of the city, seeking projects that provide advanced or concurrent environmental mitigation, and logical and compatible phasing with other projects occurring around the city. A phasing schedule has not yet been developed, but it is reasonable to expect that one to two EIPs may be pursued per year, similar to the I Street Bridge EIP completed in 2008 and the two presently proposed EIPs described in this document. An EIP was not pursued for the 2009 construction season while the WSLIP was under planning and design development.

At this time, WSAFCA is proposing the EIPs for sites on the Sacramento Bypass and Sacramento River North levee reaches, referred to as the CHP Academy EIP and The Rivers EIP, respectively. These sites have both had observed past performance issues, with evidence of seepage at both sites (and possible boils at The Rivers). The sites are analyzed at a project level in this EIS/EIR. Table 2-18 provides an overview of the deficiencies and upgrades proposed at these sites for flood management. Recreation improvements are also proposed.

Table 2-18. CHP Academy and The Rivers EIP Alternatives

EIP	Program Component	Applicant Preferred Alternative	Alternative B
CHP Academy	Flood	Slurry cutoff wall and waterside slope flattening	Stability berm with interior drain, and relief wells
	Recreation	Paved bike trail	Paved bike trail
The Rivers	Flood	DSM cutoff wall and landside slope flattening (landside hinge point stationary, kick out toe)	Deep sheet pile wall and landside slope flattening
	Recreation	Paved bike trail, paved pedestrian trail, paved landing, landside levee embankment ramps	Paved bike trail, paved pedestrian trail, paved landing, landside levee embankment ramps

2.8.2 CHP Academy EIP

2.8.2.1 Introduction

The CHP Academy EIP encompasses approximately 6,500 feet of the Sacramento Bypass Levee, (Figure 2-23). The easternmost 1,200 feet of the waterside slope of the levee (adjacent to the weir) is lined with a concrete cap. This concrete cap prevents the levee from eroding when the weir is open and water is allowed to enter into the Sacramento Bypass from the Sacramento River. A stability berm and an interior drain system installed as part of the West Sacramento Project in 1999 runs the length of the levee on the landside. Deficiencies at this site are through-seepage, geometry, and under-seepage, along with short reaches of instability.

Two project alternatives for the CHP Academy EIP have been carried forward for analysis in this EIS/EIR. These alternatives are summarized in Table 2-19. A complete screening and description of the CHP Academy project-level flood and recreation alternatives are discussed in detail in Chapter 4.

Table 2-19. CHP Academy EIP Flood Improvement Alternatives

EIP	Station Ranges		Deficiencies	Applicant Preferred Alternative Levee Treatments	Alternative B Levee Treatments
CHP Academy EIP (18+50 to 64+78)	18+00	60+00	Through-seepage, under-seepage, stability, geometry	Slurry cutoff wall and waterside slope flattening	Stability berm with interior drain and relief wells
	60+00	64+78	Through-seepage, stability, geometry	Slurry cutoff wall and waterside slope flattening to weir	Stability berm with interior drain and relief wells

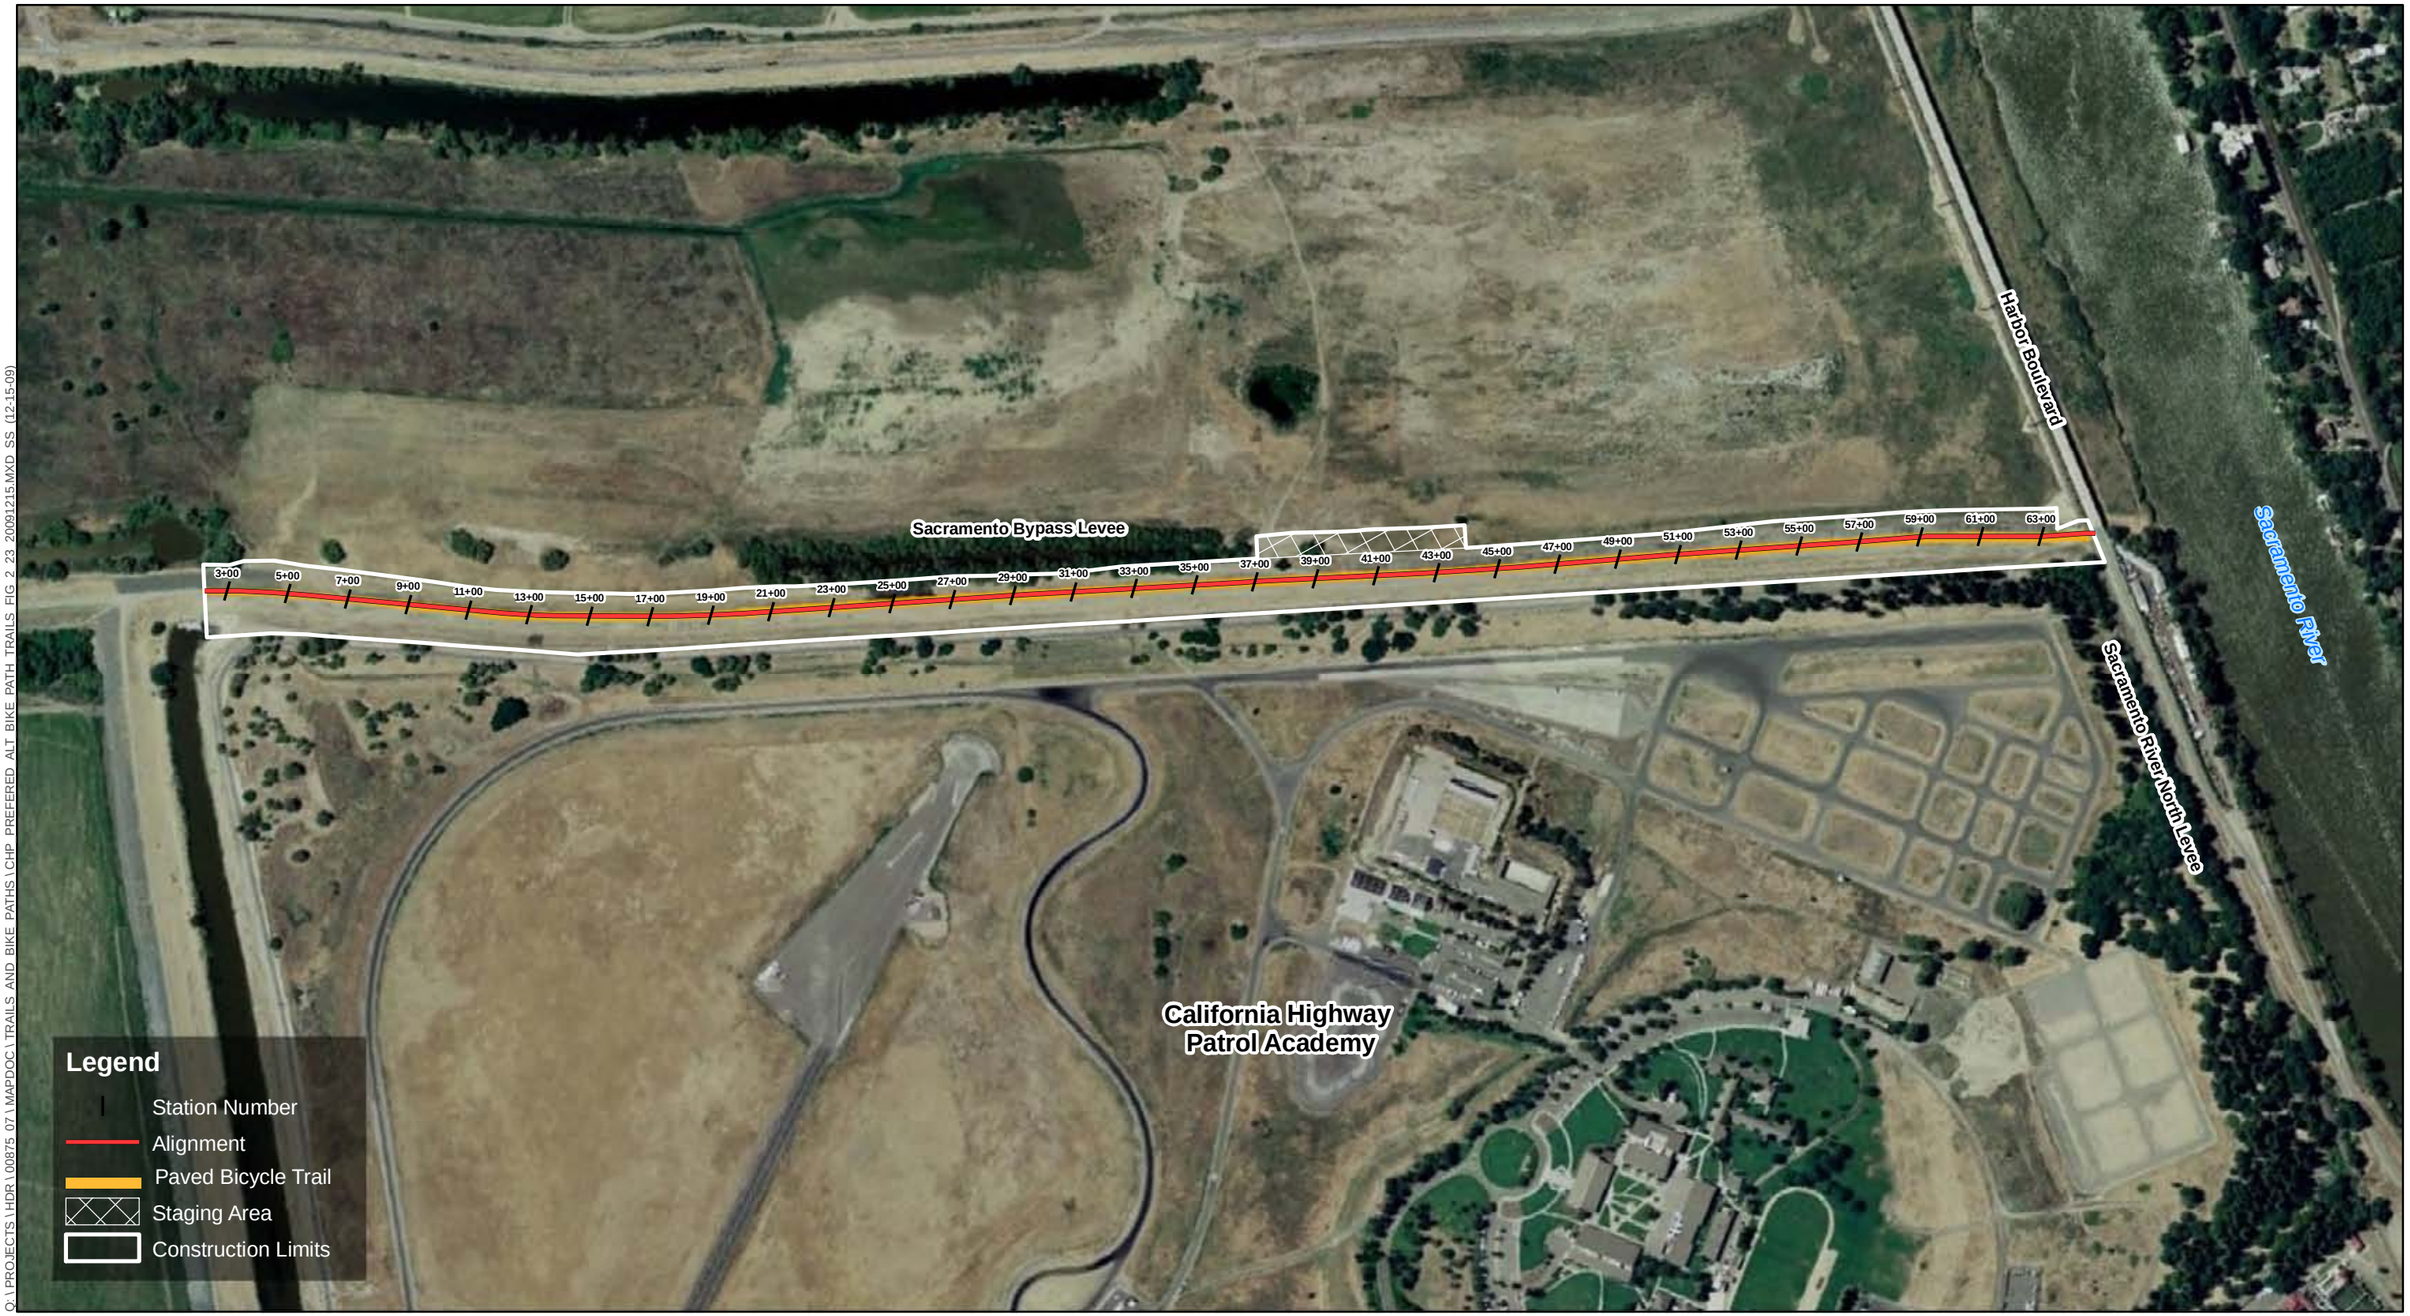
2.8.3 The Rivers EIP

2.8.3.1 Introduction

The Rivers EIP area is approximately 4,500 feet long and is located on the Sacramento River North Levee, just north of the confluence of the Sacramento and American Rivers, including part of The Rivers residential development (Figure 2-24). Levee deficiencies at this site include geometry, stability, through-seepage, and under-seepage.



Bryte Park/Riverbank Elementary School and The Rivers residential development are located south of The Rivers EIP. The DWR maintenance yard is located directly west of the site. A leaking underground storage tank for gasoline and diesel was discovered and removed from the DWR maintenance yard in 1994. Monitoring and sampling of groundwater and soil at and in the vicinity of the site of contamination began in September 2001 with the intent to explore the extent of the fuels-impacted groundwater and provide data on risk to sensitive receptors. A small portion of the plume is located within the footprint of western end of the project site (see Section 3.3, Water Quality and Groundwater Resources). DWR has created a work plan with the Regional Water Quality Control Board (RWQCB) to continue to monitor the site, which includes the installation of additional Two project alternatives for The Rivers EIP have been carried forward for analysis in this EIS/EIR. These alternatives are summarized in Table 2-20. A complete screening and description of The Rivers EIP project-level flood and recreation alternatives are discussed in detail in Chapter 5.

Environmental commitments are measures incorporated as part of the program and project description, meaning they are proposed as elements of the proposed action and are to be considered in conducting the environmental analysis and determining effects and findings. The purpose of environmental commitments is to reflect and incorporate best practices into the program and project that avoid, minimize, or offset potential environmental effects. *Note: The term* mitigation *is specifically applied in this EIS/EIR only to designate measures required to reduce environmental effects triggering a finding of significance.* These best practices tend to be relatively standardized and compulsory; they represent sound and proven methods to reduce the potential effects of an action. The rationale behind including environmental commitments is that the project proponent commits to undertake and implement these measures as part of the project in advance of effect findings and determinations in good faith to improve the quality and integrity of the project, streamline the environmental analysis, and demonstrate responsiveness and sensitivity to environmental quality. Environmental commitments apply to each and all improvements other than the No Action Alternative.

To avoid and minimize construction-related effects, WSAFCA would implement the following environmental commitments at the program and project levels to reduce or offset short-term, construction-related effects. Measures have been developed for each of the topics below, to be applied in the program- and project-level resource analyses (Chapters 3, 4, and 5).

2.9.1.1 Raptors

For construction between March 1 and August 1, WSAFCA will perform preconstruction surveys to determine whether raptors are nesting or roosting at or adjacent to staging or construction areas. In the event nesting or roosting raptors are identified, WSAFCA will coordinate with DFG to identify measures to ensure raptors are not adversely affected. These measures may include implementation of suitable buffers and phasing of construction.

2.9.1.2 USACE Levee Vegetation Guidance

In complying with the USACE levee vegetation guidance, WSAFCA will, to the greatest extent possible, avoid and minimize the removal of vegetation that provides habitat for endangered species such as anadromous fish species. Where conflicts may arise between the USACE levee vegetation guidance and compliance with the City's policies to protect trees and riparian vegetation, coordination between the appropriate parties will be conducted to discuss a mutually agreeable approach to achieve compliance, and/or to decide to pursue a variance from the USACE.

2.9.1.3 Protected Trees and Riparian Trees

WSAFCA will comply with the City tree ordinance requirements and will implement the following measures.

- Protect heritage trees that occur in the vicinity of the project site and outside the construction area by installing protective fencing. Protective fencing will be installed along the edge of the construction area (including temporary and permanent access roads) where construction will occur within 20 feet of the dripline of an oak or native tree 6 inches or more in diameter at 4.5 feet above the ground (as determined by a qualified biologist or arborist).

- Provide signs along the protective fencing at a maximum spacing of one sign per 100 feet of fencing stating that the area is environmentally sensitive and that no construction or other operations may occur beyond the fencing.
- Retain a certified arborist to perform any necessary pruning of oak or native trees along the construction area, in accordance with International Society of Arboriculture standards.
- Prepare tree and riparian habitat mitigation and monitoring plans. Potential mitigation areas will be evaluated by a qualified restoration ecologist, biologist, or certified arborist to determine their suitability to support the target native tree species.

2.9.1.4 Invasive Plant Species Prevention

The program proponent will implement one or more of the following actions to avoid and minimize the spread or introduction of invasive plant species. In addition, the program proponent will coordinate with the Yolo County Agricultural Commissioner to ensure that the appropriate BMPs are implemented for the duration of the construction of proposed projects.

- Clean construction equipment and vehicles in a designated wash area prior to entering and exiting the project site.
- Educate construction supervisors and managers about invasive plant identification and the importance of controlling and preventing the spread of invasive plant infestations.
- Treat small, isolated infestations with eradication methods that have been approved by or developed in conjunction with the Yolo County Agricultural Commissioner to prevent and/or destroy viable plant parts or seeds.
- Minimize surface disturbance to the greatest extent feasible to complete the work.
- Use native, non-invasive species or non-persistent hybrids in erosion-control plantings to stabilize site conditions and prevent invasive plant species from colonizing.
- Use weed-free imported erosion-control materials (or rice straw) in upland areas.
- One year after construction, conduct a monitoring visit to ensure that no new occurrences have established.

2.9.1.5 Stormwater Pollution Prevention Plan

Because ground disturbance for each project would be greater than 1 acre, WSAFCA will obtain coverage under the U.S. Environmental Protection Agency's (EPA's) National Pollutant Discharge Elimination System (NPDES) general construction activity stormwater permit. The Central Valley RWQCB administers the NPDES storm water permit program in Yolo County. Obtaining coverage under the NPDES general construction activity permit generally requires that the project applicant prepare a stormwater pollution prevention plan (SWPPP) that describes the best management practices (BMPs) that will be implemented to control accelerated erosion, sedimentation, and other pollutants during and after project construction.

The specific BMPs that will be incorporated into the erosion and sediment control plan and SWPPP will be determined during the final design phase of the selected improvement, and will be prepared by the construction contractor in accordance with the California RWQCB Field Manual. However, the plan likely will include, but not be limited to, one or more of the following standard erosion and sediment control BMPs.

- **Timing of construction**. The construction contractor will conduct all construction activities during the typical construction season to avoid ground disturbance during the rainy season.
- **Staging of construction equipment and materials**. To the extent possible, equipment and materials will be staged in areas that have already been disturbed.
- **Minimize soil and vegetation disturbance**. The construction contractor will minimize ground disturbance and the disturbance/destruction of existing vegetation. This will be accomplished in part through the establishment of designated equipment staging areas, ingress and egress corridors, and equipment exclusion zones prior to the commencement of any grading operations.
- **Stabilize grading spoils**. Grading spoils generated during the construction will be temporarily stockpiled in staging areas. Silt fences, fiber rolls, or similar devices will be installed around the base of the temporary stockpiles to intercept runoff and sediment during storm events. If necessary, temporary stockpiles may be covered with an appropriate geotextile to increase protection from wind and water erosion.
- **Install sediment barriers**. The construction contractor may install silt fences, fiber rolls, or similar devices to prevent sediment-laden runoff from leaving the construction area.
- **Stormwater drain inlet protection**. The construction contractor may install silt fences, drop inlet sediment traps, sandbag barriers, and/or other similar devices.
- **Permanent site stabilization**. The construction contractor will install structural and vegetative methods to permanently stabilize all graded or otherwise disturbed areas once construction is complete. Structural methods may include the installation of biodegradable fiber rolls and erosion control blankets. Vegetative methods may involve the application of organic mulch and tackifier and/or the application of an erosion control seed mix. Implementation of a SWPPP will substantially minimize the potential for project-related erosion and associated adverse effects on water quality.

2.9.1.6 Temporary Visual Barriers between Construction Zones and Residences

The program proponent or the contractor will install fencing (such as chain link with slats or fencing made of windscreen material) or other structures where determined appropriate to obstruct undesirable views of construction activities from residences' backyards and front yards that abut the project sites. The fencing will be approximately 7 feet high to help maintain the privacy of residents.

2.9.1.7 Noise-Reducing Construction Practices

WSAFCA will require the construction contractor to follow noise-reducing construction practices such that noise from construction does not exceed applicable City noise ordinance limits or, at a minimum, implements measures to reduce noise to acceptable levels. Measures that can be used to limit noise may include but are not limited to the following actions:

- locating equipment as far as practical from noise-sensitive uses,
- using sound control devices such as mufflers on equipment,
- using equipment that is quieter than standard equipment,

- using noise-reducing enclosures around noise-generating equipment, and
- provide for temporary relocation if noise will exceed acceptable levels for an extended duration (as discussed below).

2.9.1.8 Property Acquisition Compensation for Loss of Business, and Temporary Resident Relocation Plan

Several of the improvements proposed under the program will require land acquisition and may require removal of residences to accommodate the expanded footprint of the levee system. Permanent land acquisition may be necessary for implementation of adjacent levee raises, full levee raises, relief wells, seepage berms, slope flattening, stability berms, and setback levees. In addition, sufficient land will need to be acquired to establish an appropriate maintenance corridor at the landside toes of all improved levees. Permanent acquisition, relocation, and compensation services will be conducted in compliance with Federal and state relocation laws, which are the Uniform Act of 1970 (42 USC 4601 *et seq.)* and implementing regulation, 49 CFR Part 24; and California Government Code Section 7267 *et seq.* These laws require that appropriate compensation be provided to displaced landowners and tenants, and that residents be relocated to comparable replacement housing.

In some cases, construction of levee improvements may result in temporary disruption of utilities (water, telephone, electricity, gas, and sanitary sewer) or loss of vehicle or pedestrian access could occur for durations too lengthy for convenient day-to-day living and/or construction-related noise may occur outside City ordinance limits. During some periods of time, construction activities may be directly adjacent to homes. In these cases, WSAFCA will provide assistance for residents to temporarily relocate during construction activities and provide compensation to residents for reasonable rent and living expenses incurred due to relocation. WSAFCA will develop a Temporary Resident Relocation Plan to guide temporary relocation services and compensation. The Temporary Resident Relocation Plan will, at a minimum, serve the following functions:

- outline the process for providing notice of relocation,
- provide guidelines for relocation services and compensation,
- ensure that 24-hour security for vacated homes is provided,
- provide for temporary occasional access of vacated homes by residents (for long-duration construction periods, and
- ensure all compensation and relocation activities are conducted in compliance with Federal and state relocation laws, which are identified above.

2.9.1.9 Traffic Control and Road Maintenance Plan

WSAFCA, in coordination with relevant City and county public works departments, will develop and implement traffic control plan(s) for the proposed project.

A traffic control plan describes the methods of traffic control to be used during construction. All on-street construction traffic will be required to comply with the local jurisdiction's standard construction specifications. The plan will reduce the effects of construction on the roadway system in the project area throughout the construction period. Construction contractors will follow the standard construction specifications of affected jurisdictions and obtain the appropriate

encroachment permits, if required. The conditions of the encroachment permit will be incorporated into the construction contract and will be enforced by the agency that issues the encroachment permit.

Road closures may be of varying duration, measured in hourly periods or up to several weeks in some instances. Proposed lane closures during the a.m. and p.m. commuting hours will be coordinated with the appropriate jurisdiction and minimized during the morning and evening peak traffic periods. Commuters will be notified of the construction schedule to help avoid potential disruptions. Standard construction specifications also typically limit lane closures during commuting hours. Lane closures will be kept as short as possible and detour signage, if detours are available, will be posted around construction sites. Advance notice signs of upcoming construction activities will be posted at least 1 week in advance so that road and rail users are able to avoid traveling through the construction area during these times or at least aware of inconveniences.

Safe pedestrian and bicyclist access, if any exists on the current roadway, will be maintained in or around the construction areas at all times. Construction areas will be secured as required by the applicable jurisdiction to prevent pedestrians and bicyclists from entering the work site, and all stationary equipment will be located as far away as possible from areas where bicyclists and pedestrians are present. WSAFCA will notify and consult with emergency service providers to maintain emergency access and facilitate the passage of emergency vehicles on city streets.

WSAFCA will provide adequate parking for construction trucks, equipment, and construction workers within the designated staging areas throughout the construction period. If inadequate space for parking is available at a given work site, WSAFCA will provide an off-site staging area and, as needed, coordinate the daily transport of construction vehicles, equipment, and personnel to and from the work site.

The traffic control plan will also include the information listed below.

- A street layout showing the location of construction activity and surrounding streets to be used as detour routes, including special signage.
- A tentative start date and construction duration period for each phase of construction.
- The name, address, and emergency contact number for those responsible for maintaining the traffic control devices during the course of construction.

Additionally, the traffic control plan will include the stipulations listed below.

- Access for driveways and private roads will be maintained, except for brief periods of construction, in which case property owners will be notified.
- Traffic controls may include flag persons wearing Occupational Safety and Health Administration-approved vests and using a Stop/Slow paddle to warn motorists of construction activity.
- Access to transit services will be maintained and public transit vehicles will be detoured.
- Contractors will be informed in writing of appropriate routes to and from construction sites, and weight and speed limits for local roads used to access construction sites. All such written notifications will be submitted to the City of West Sacramento Planning Department.

WSAFCA will assess damage to roadways used during construction and will repair all potholes, fractures, or other damages.

2.9.1.10 Coordination to Ensure Minimal Overlap in Disturbances to Traffic during WSLIP Construction

WSAFCA will coordinate with the City prior to starting any construction activities to determine if any other projects would disrupt traffic or require detours affecting the same roads. If so, WSAFCA will modify haul routes, timing, or otherwise work with the City and other project proponents to minimize cumulative disruptions to roadways.

2.9.1.11 Coordination of Construction Periods with Railroad Service Officials

WSAFCA will coordinate directly with railroad officials, including Union Pacific Railroad, Amtrak, Sierra Northern Railway, and Burlington Northern Santa Fe, regarding the timing of temporary railroad closures and/or removals as necessary during program implementation. WSAFCA will ensure minimization of any disruption to service by utilizing the most recent and available construction methods to expedite activities. Because the temporary loss of service along some railroads could result in financial loss for various companies that use the rail lines, WSAFCA will ensure that the appropriate entities are compensated for monetary losses attributed to the reduction in rail service.

2.9.1.12 Coordination of Construction Periods with the Port of West Sacramento

WSAFCA will ensure that the contractor coordinates construction periods with the Port of West Sacramento in order to achieve the following objectives:

- ensure shipping schedules are not affected,
- avoid conflict between any in-water work in the DWSC and commercial vessel navigation, and
- ensure that vehicle access to the port is maintained during construction.

2.9.1.13 Coordination of Construction Periods with CHP

WSAFCA will coordinate directly with CHP regarding the timing and nature of construction activities near the CHP Academy in order to achieve the following objectives:

- ensure training and other activities are not affected by construction, and
- ensure safety and security is not compromised in any way,

2.9.1.14 Notification of Construction Area Closure

WSAFCA will ensure that the contractor posts notice of construction activities and intended days of construction area closure at least 30 days in advance of closures in and near formal recreation facilities. The contractor will post notice of construction activities and closures at least 10 days in advance in all other areas. Notice should be posted adjacent to access roads, and signs will be at least 3 square feet in size and provide a contact for questions regarding project construction. WSAFCA also will ensure that the construction area is fenced off to keep members of the public out of harm's way.

2.9.1.15 Reconstruction of Affected Formal Park Facilities

If removal of formal park facilities is required during construction of any of the levee improvements, WSAFCA will ensure to the greatest degree possible that these facilities are replaced on site after construction. If on-site replacement is not possible, WSAFCA will work with the City's Department of Parks and Recreation to determine an appropriate location for facility replacement. This environmental commitment applies (but is not limited) to the trail connecting the Yolo Causeway Bicycle Path to West Capitol Avenue at Roland Hensley Bike Park, the Barge Canal Recreational Access and associated hand-launch boat ramp, and the soccer field and running track at Bryte Park.

2.9.1.16 Preservation of Marina and Boat Launch Access

WSAFCA will ensure that access to marina and boat launch facilities is maintained to the greatest degree possible during construction of levee improvements. If access restrictions cannot be avoided, WSAFCA will post notice regarding the location of alternative marina and boat launch facilities at least 30 days in advance of closure and will ensure that closure time is minimized and/or provide alternate access routes to the facilities.

2.9.1.17 Minimization of Construction-Related Effects on Navigation

During any in-channel construction activities, WSAFCA will implement the following measures to ensure that construction-related effects on navigation and recreational boating are minimized:

- avoid or limit construction during major summer holiday periods if possible or limited; and
- post warning signs and buoys at, upstream of, and downstream of all construction equipment, sites, and activities.

2.9.1.18 Approval for Broderick Boat Ramp Closure

If closure of the Broderick Boat Ramp cannot be avoided during construction, WSAFCA will obtain approval for closure from the Department of Boating and Waterways. Prior approval for facility closure is a requirement of the City's grant agreement with the Department of Boating and Waterways.

2.9.1.19 Bentonite Slurry Spill Contingency Plan (Frac-Out Plan)

WSAFCA will ensure the contractor will prepare and implement a bentonite slurry spill contingency plan (BSSCP) for any excavation activities that use pressurized fluids (other than water). If the contactor prepares the plan, it will be subject to approval by USACE, NMFS, and WSAFCA before excavation can begin. The BSSCP will include measures intended to minimize the potential for a frac-out (short for "fracture-out event") associated with excavation and tunneling activities; provide for the timely detection of frac-outs; and ensure an organized, timely, and "minimum-effect" response in the event of a frac-out and release of excavation fluid (i.e., bentonite). The BSSCP will require, at a minimum, the following measures.

- If a frac-out is identified, all work will stop, including the recycling of the bentonite fluid. In the event of a frac-out into water, the location and extent of the frac-out will be determined, and the frac-out will be monitored for 4 hours to determine whether the fluid congeals (bentonite will usually harden, effectively sealing the frac-out location).

- NMFS, DFG, and the RWQCB will be notified immediately of any spills and will be consulted regarding clean-up procedures. A Brady barrel will be on site and used if a frac-out occurs. Containment materials, such as straw bales, also will be on site prior to and during all operations and a vacuum truck will be on retainer and available to be operational on site within notice of 2 hours. The site supervisor will take any necessary follow-up response actions in coordination with agency representatives. The site supervisor will coordinate the mobilization of equipment stored at staging areas (e.g., vacuum trucks) as needed.
- If the frac-out has reached the surface, any material contaminated with bentonite will be removed by hand to a depth of 1-foot, contained, and properly disposed of, as required by law. The drilling contractor will be responsible for ensuring that the bentonite is either properly disposed of at an approved Class II disposal facility or properly recycled in an approved manner.
- If the bentonite fluid congeals, no other actions, such as disturbance of the streambed, will be taken that will potentially suspend sediments in the water column.
- The site supervisor has overall responsibility for implementing this BSSCP. The site supervisor will be notified immediately when a frac-out is detected. The site supervisor will be responsible for ensuring that the biological monitor is aware of the frac-out, coordinating personnel, response, cleanup, regulatory agency notification and coordination to ensure proper clean-up, disposal of recovered material, and timely reporting of the incident. The site supervisor will ensure all waste materials are properly containerized, labeled, and removed from the site to an approved Class II disposal facility by personnel experienced in the removal, transport, and disposal of drilling mud.
- The site supervisor will be familiar with the contents of this BSSCP and the conditions of approval under which the activity is permitted to take place. The site supervisor will have the authority to stop work and commit the resources (personnel and equipment) necessary to implement this plan. The site supervisor will ensure that a copy of this plan is available (on site) and accessible to all construction personnel. The site supervisor will ensure that all workers are properly trained and familiar with the necessary procedures for response to a frac-out, prior to commencement of excavation operations.

2.9.1.20 Spill Prevention, Control, and Counter-Measure Plan

A spill prevention, control, and counter-measure plan (SPCCP) is intended to prevent any discharge of oil into navigable water or adjoining shorelines. WSAFCA or its contractor will develop and implement an SPCCP to minimize the potential for and effects from spills of hazardous, toxic, or petroleum substances during construction and operation activities. The SPCCP will be completed before any construction activities begin. Implementation of this measure will comply with state and Federal water quality regulations. The SPCCP will describe spill sources and spill pathways in addition to the actions that will be taken in the event of a spill (e.g., an oil spill from engine refueling will be immediately cleaned up with oil absorbents). The SPCCP will outline descriptions of containments facilities and practices such as doubled-walled tanks, containment berms, emergency shut-offs, drip pans, fueling procedures and spill response kits. It will also describe how and when employees are trained in proper handling procedure and spill prevention and response procedures.

WSAFCA will review and approve the SPCCP before onset of construction activities and routinely inspect the construction area to verify that the measures specified in the SPCCP are properly

implemented and maintained. WSAFCA will notify its contractors immediately if there is a non-compliance issue and will require compliance.

The Federal reportable spill quantity for petroleum products, as defined in 40 CFR 110, is any oil spill that:

- violates applicable water quality standards,
- causes a film or sheen on or discoloration of the water surface or adjoining shoreline, or
- causes a sludge or emulsion to be deposited beneath the surface of the water or adjoining shorelines.

If a spill is reportable, the contractor's superintendent will notify WSAFCA, and WSAFCA will take action to contact the appropriate safety and cleanup crews to ensure that the SPCCP is followed. A written description of reportable releases must be submitted to the Central Valley RWQCB. This submittal must contain a description of the release, including the type of material and an estimate of the amount spilled, the date of the release, an explanation of why the spill occurred, and a description of the steps taken to prevent and control future releases. The releases will be documented on a spill report form.

2.9.1.21 Implementation of Measures to Maintain Surface Water Quality and Groundwater Quality

If an appreciable spill has occurred and results determine that program activities have adversely affected surface or groundwater quality, a detailed analysis will be performed by a registered environmental assessor or professional engineer to identify the likely cause of contamination. This analysis will conform to American Society for Testing and Materials (ASTM) standards and will include recommendations for reducing or eliminating the source or mechanisms of contamination. Based on this analysis, the WSAFCA and its contractors will select and implement measures to control contamination, with a performance standard that surface water quality and groundwater quality must be returned to baseline conditions.

2.9.1.22 Monitoring of Turbidity in Adjacent Water Bodies

WSAFCA or its contractor will monitor turbidity in the adjacent water bodies, where applicable criteria apply, to determine whether turbidity is being affected by construction and ensure that construction does not affect turbidity levels, which ultimately increase the sedimentation loads.

The Basin Plan contains turbidity objectives for the Sacramento River. Specifically, the plan states that where natural turbidity is between 5 and 50 Nephelometric turbidity units (NTUs), turbidity levels may not be elevated by 20% above ambient conditions. Where ambient conditions are between 50 and 100 NTUs, conditions may not be increased by more than 10 NTUs.

WSAFCA or its contractor will monitor ambient turbidity conditions upstream during construction. Monitoring will continue approximately 200 feet downstream of construction activities to determine whether turbidity is being affected by construction. Grab samples will be collected at a downstream location that is representative of the flow near the construction site. If there is a visible sediment plume being created from construction, the sample should represent this plume. Monitoring should occur hourly when construction encroaches into the Sacramento River. If

construction does not encroach into the river, the monitoring should occur once a week on a random basis.

If turbidity limits exceed Basin Plan standards, construction-related earth-disturbing activities will slow to a point that results in alleviating the problem. WSAFCA will notify the Central Valley RWQCB of the issue and provide an explanation of the cause.

2.9.1.23 Soil Supply Protection Measures

WSAFCA's first choice for fill or borrow material will be from a local commercial quarry or other permitted source. In the event that material is desired from a source that is not presently permitted, for reasons such as quality, proximity, or volume available, WSAFCA will implement soil supply protection measures.

- One such measure will be maximizing on-site use through gradation, placement, and treatment.
- Another measure will be the preservation and replacement of topsoil at borrow sites, so that they could be continued to be used for their current use or otherwise returned to their pre-project condition. As part of borrow operations, the upper 12 inches of topsoil would be set aside and replaced after project construction in each construction season. After the project is completed, the borrow site would be re-contoured and reclaimed.
- If potential borrow sites are identified within a 10,000-foot Airport Critical Zone, management of the grasslands created by borrow operations would be consistent with the Airport's *Wildlife Hazard Management Plan* (Sacramento County Airport System 2007).
- An additional measure would be independent environmental documentation and regulatory compliance, as required. Specific regulations related to soil resources are detailed in Section 3.4.2.1.

Chapter 3
Affected Environment and Environmental Consequences

3.1 Introduction

This chapter provides the Affected Environment and Environmental Consequences for the WSLIP.

The baseline environmental conditions assumed in the preparation of this chapter consist of the existing physical environment as of January 28, 2009, when WSAFCA published the Notice of Preparation (NOP) to prepare an EIR with the State Clearinghouse. USACE published a Notice of Intent (NOI) to prepare an EIS in the *Federal Register* on January 27, 2009.

3.1.1 Resources

- Section 3.2 Flood Control and Geomorphic Conditions
- Section 3.3 Water Quality and Groundwater Resources
- Section 3.4 Geology, Seismicity, Soils, and Mineral Resources
- Section 3.5 Transportation and Navigation
- Section 3.6 Air Quality and Climate Change
- Section 3.7 Noise
- Section 3.8 Vegetation and Wetlands
- Section 3.9 Fisheries and Aquatics
- Section 3.10 Wildlife
- Section 3.11 Land Use and Agriculture
- Section 3.12 Socioeconomic and Community Effects
- Section 3.13 Environmental Justice
- Section 3.14 Visual Resources
- Section 3.15 Recreation
- Section 3.16 Utilities and Public Services
- Section 3.17 Public Health and Environmental Hazards
- Section 3.18 Cultural Resources

Section 3.2
Flood Control and Geomorphic Conditions

3.2.1 Introduction

This section presents the affected environment and environmental consequences related to hydrologic, hydraulic, geomorphic, and flood control issues associated with the program and project treatment alternatives for the WSLIP. The affected environment includes the applicable Federal and state regulations that govern construction and maintenance of the WSLIP and the hydrologic, hydraulic, and geomorphic environmental setting.

The environmental consequences section describes potential hydraulic, geomorphic, and flood control effects associated with the program and EIP project-level treatment alternatives. It describes the methods used to determine the effects of the programs and project alternatives and lists the thresholds used to conclude whether an effect would be significant. Effects were determined by using hydraulic modeling results, significance criteria set forth in the State CEQA Guidelines, and professional judgment. Measures to mitigate (i.e., avoid, minimize, rectify, reduce, eliminate, or compensate for) significant effects accompany each effect discussion.

Implications of WSLIP program and project treatment alternatives for flood control and geomorphic conditions are also addressed within the context of the resources affected by the changes, most notably under Section 3.3, Water Quality and Groundwater Resources; Section 3.4, Geology, Seismicity, Soils, and Mineral Resources; Section 3.8, Vegetation and Wetlands; and Section 3.9, Fisheries and Aquatics. The key sources of data and information used in the preparation of this chapter are listed and briefly described below.

- *Historic Sediment Loads in the Sacramento–San Joaquin Delta*, California Department of Water Resources, October 1994
- *Assessment of Sediment Budget of Sacramento–San Joaquin Delta*, Northwest Hydraulic Consultants, 2003
- *North Delta Sedimentation Study,* Northwest Hydraulic Consultants, prepared for California Department of Water Resources, March 2006
- *Surficial Geologic Mapping and Geomorphic Assessment*, California Department of Water Resources Urban Levees, West Sacramento, California, William Lettis & Associates, April 2007
- *West Sacramento Levees System: Problem Identification Report, Erosion Assessment and Treatment Alternatives*, Draft for Review, Northwest Hydraulic Consultants, prepared for HDR, Inc./Jones & Stokes, September 2007
- *West Sacramento Levee Evaluation Project, Administrative Draft, Problem Identification Report*, HDR, Inc., prepared for the City of West Sacramento, January 2008
- *West Sacramento Levee Evaluation Program, Administrative Draft, Alternatives Analysis,* HDR, Inc., November 2009
- *Hydraulics Report for the City of West Sacramento* Levee Alternatives Analysis, MBK Engineers, March 28, 2007

- *Evaluating the Effects of the Sacramento River West Levee Setback at Oak Hall Bend,* MBK Engineers, April 18, 2007
- *Summary Report on Hydraulic Impacts of the West Sacramento Levee Improvement Project (Draft),* MBK Engineers, June 22, 2009
- *Hydraulic Impact Analysis of Cumulative Development in Sacramento River Corridor Floodway,* MBK Engineers, June 27, 2005
- *Report on Effects of Projected Sea-Level Change on West Sacramento Levee Improvement Project Design*, MBK Engineers, November 20, 2009

The following document is included as Appendix C of this document.

- *(Draft) Summary Report on Hydraulic Impacts of the West Sacramento Levee Improvement Project*, MBK Engineers, June 22, 2009

3.2.2 Affected Environment

3.2.2.1 Regulatory Setting

This section describes the Federal and state regulations, laws, and policies that pertain to hydrology, hydraulics, geomorphic conditions, and flood control issues within the proposed program area.

3.2.2.1.1 Federal

National Flood Insurance Program

The National Flood Insurance Act of 1968 and the Flood Disaster Protection Act of 1973 were intended to reduce the need for large, publicly funded flood control structures and disaster relief by restricting development on floodplains. FEMA administers the National Flood Insurance Program (NFIP) to subsidize flood insurance to communities that comply with FEMA regulations limiting development in floodplains. FEMA issues Flood Insurance Rate Maps (FIRMs) for communities participating in the NFIP. These maps delineate flood hazard zones in the community. These maps are designed for flood insurance purposes only and do not necessarily show all areas subject to flooding. The maps designate lands likely to be inundated during a 100-year storm event and elevations of the base flood. They also depict areas between the limits affected by 100-year and 500-year events and areas of minimal flooding. These maps often are used to establish building pad elevations to protect new development from flooding effects. The locations of FEMA-designated floodplains in the proposed program area are included in the Environmental Setting discussion below.

Requirements for Federal Emergency Management Agency Certification

For guidance on floodplain management and floodplain hazard identification, communities turn to FEMA guidelines, as defined in 44 CFR 59 through 77. In order for a levee to be recognized by FEMA under the NFIP, the community must provide evidence demonstrating that adequate design and operation and maintenance systems are in place to provide reasonable assurance that protection from the base flood (1% or 100-year flood) exists. These specific requirements are outlined in 44 CFR 65.10, Mapping of Areas Protected by Levee Systems, and are summarized below.

Levee height. Riverine levees must provide a minimum freeboard (the height of the top of a levee above a given level of water in a river) of 3 feet above the water-surface level of the base flood. An additional 1 foot above the minimum is required within 100 feet of either side of structures (such as bridges) riverward of the levee or wherever the flow is constricted. An additional 0.5 foot above the minimum at the upstream end of the levee, tapering to not less than the minimum at the downstream end of the levee, also is required.

Closures. All openings must be provided with closure devices that are structural parts of the system during operation and designed according to sound engineering practice.

Embankment protection. Engineering analyses must be submitted that demonstrate that no appreciable erosion of the levee embankment can be expected during the base flood, as a result of either currents or waves, and that anticipated erosion will not result in failure of the levee embankment or foundation directly or indirectly through reduction of the seepage path and subsequent instability.

Embankment and foundation stability. Engineering analyses that evaluate levee embankment stability must be submitted to FEMA. The analyses provided shall evaluate expected seepage during loading conditions associated with the base flood and shall demonstrate that seepage into or through the levee foundation and embankment will not jeopardize embankment or foundation stability.

Settlement. Engineering analyses must be submitted that assess the potential and magnitude of future losses of levee height as a result of levee settlement and demonstrate that freeboard will be maintained within the minimum standards.

Interior drainage. An analysis must be submitted that identifies the source(s) of such flooding, the extent of the flooded area, and, if the average depth is greater than 1 foot, the water-surface elevation(s) of the base flood.

Operation plans. For a levee system to be recognized, a formal plan of operation must be provided to FEMA. All closure devices or mechanical systems for internal drainage, whether manual or automatic, must be operated in accordance with an officially adopted operational manual, a copy of which must be provided to FEMA.

Maintenance plans. For levee systems to be recognized as providing protection from the base flood, they must be maintained in accordance with an officially adopted maintenance plan. All maintenance activities must be under the jurisdiction of a Federal or state agency, an agency created by Federal or state law, or an agency of a community participating in the NFIP that must assume ultimate responsibility for maintenance. The plan must document the formal procedure that ensures that the stability, height, and overall integrity of the levee and its associated structures and systems are maintained. At a minimum, maintenance plans must specify the maintenance activities to be performed, the frequency of their performance, and the person by name or title responsible for their performance.

U.S. Army Corps of Engineers Levee Design Criteria

A majority of the levees included in the proposed program area are federally authorized and fall within the jurisdiction of USACE. The levee evaluation for the proposed program area conforms to the engineering criteria established by USACE for the assessment and repair of levees. The USACE technical criteria in the following bullet list should be used as guidance unless noted otherwise.

- Overtopping of Flood Control Levees and Floodwalls (Publication ETL 1110-2-299, August 22, 1986)
- Structural Design of Closure Structures for Local Flood Protection Projects (Publication EM 1110-2-2705, March 31, 1994)
- Design of Coastal Revetments, Seawalls, and Bulkheads (Publication EM 1110-2-1614, June 30, 1995)
- Design Guidance on Levees (Publication ETL 1110-2-555, November 30, 1997)
- Conduits, Culverts, and Pipes (Publication EM 1110-2-2902, March 31, 1998)
- Guidelines on Ground Improvement for Structures and Facilities (Publication ETL 1110-1-185, February 1, 1999)
- Engineering and Design for Civil Works Projects (Publication ER 1110-2-1150, August 31, 1999)
- Design and Construction of Levees (Publication EM 1110-2-1913, April 30, 2000)
- Geotechnical Investigations (Publication EM 1110-1-1804, January 1, 2001)
- USACE CESPK Levee Task Force, Recommendations for Seepage Design Criteria, Evaluation and Design Practices (2003)
- Slope Stability (Publication EM 1110-2-1902, October 31, 2003)
- Geotechnical Levee Practice (Publication SOP EDG-03, June 28, 2004)
- Engineering and Design—Design Guidance for Levee Underseepage (Publication ETL 1110-2-569, May 1, 2005)
- Quality Management (Publication ER 1110-1-12, September 30, 2006)
- Engineering Technical Letter (ETL) 1110-2-571 Guidelines For Landscape Planting And Vegetation Management At Levees, Floodwalls, Embankment Dams, and Appurtenant Structures

Sacramento River Flood Control Project Levee Height Requirements for Proposed Program Area

As specified in the Design Memorandum, Volume I of II for the Sacramento River Flood Control Project, California, Mid-Valley Area, Phase III (U.S. Army Corps of Engineers 1996) and the Operation and Maintenance Manual for Channel and Levees, Sacramento River Deep Water Ship Channel Project (U.S. Army Corps of Engineers 1963), the following minimum levee height (freeboard) requirements apply to the various reaches[1].

- Sacramento River Levee: 3 feet
- Sacramento Bypass Levee: 6 feet
- Yolo Bypass Levee: 6 feet
- DWSC Levees, Port North Levee, and Port South Levee: 6 feet for the DWSC where it is adjacent to the Yolo Bypass and 3 feet for the Port (Turning Basin and Barge Canal).

[1] The freeboard requirements listed are for the Sacramento River Flood Control Project, specifically the 1957 profiles for Sacramento River, the Sacramento Bypass, and the Yolo Bypass, and the design elevations in referenced in U.S. Army Corps of Engineers (1963) for the DWSC, Port North, and Port South Levees.

Executive Order 11988 (Floodplain Management)

Executive Order 11988 addresses floodplain issues related to public safety, conservation, and economics. The order generally requires Federal agencies constructing, permitting, or funding actions meet the following requirements:

- avoid incompatible floodplain development,
- be consistent with the standards and criteria of the NFIP, and
- restore and preserve natural and beneficial floodplain values.

Section 401 of the Clean Water Act and State Regulations in Title 23 California Code of Regulations

This regulation establishes requirements for all dredging activities for navigable waters of the State of California.

Code of Federal Regulations, Title 40, Part 131, Water Quality Standards

This regulation establishes requirements for water quality, including activities related to in-channel construction, dredging, and long-term effects resulting in sediment transport and scouring.

Public Law 84-99 Delta Specific Standard

This Federal law specifies, among other findings, minimum standards to which the rehabilitation and construction of levees in the Delta should be constructed.

Section 408

This Federal law is covered in more detail in Chapter 1, Introduction, and Chapter 7, Compliance with Applicable Laws, Policies, Plans and Regulatory Framework.

3.2.2.1.2 State

Central Valley Flood Protection Board

The Central Valley Flood Protection Board (CVFPB) (formerly the California Reclamation Board) of the State of California regulates the modification and construction of levees and floodways in the Central Valley defined as part of the Sacramento Valley and San Joaquin Valley flood control projects. Rules promulgated in Title 23 of the California Code of Regulations (CCR) (Title 23, Division 1, Article 8 [Section 111 through 137]) regulate the modification and construction of levees to ensure public safety. The rules state that existing levees may not be excavated or left partially excavated during the flood season, which is generally November 1 through April 15 for the Sacramento River and Sacramento Bypass.

The following CVFPB guidance has been followed during the levee evaluation:

> The California Reclamation Board has primary jurisdiction approval of levee design and construction. The Reclamation Board standards are found in Title 23, Division 1, Article 8 (Sections 111 through 137) of the California Code of Regulations (CCR), and constitute the primary state standard. Section 120 of the CCR directs that levee design and construction be in accordance with the USACE's Engineer Manual EM 1110-2-1913, Design and Construction of Levees. This document is the primary

federal standard applicable to this project, as supplemented by additional prescriptive standards contained in Section 120 of the CCR. These additional standards prescribe minimum levee cross-sectional dimensions, construction material types, and compaction levels.

Delta Protection Act of 1992

This act declares that the basic goals of the state for the Delta are, among other findings, to improve flood protection, and therefore to ensure an increased level of public health and safety, by structural and non-structural means.

Safe, Clean, Reliable Water Supply Act

This act declares that the basic goals of the state for the Delta are, among other findings, to protect the integrity of the state's water supply system from catastrophic failure attributable to earthquakes and flooding.

3.2.2.1.3 Local

Yolo County

The Health and Safety Element of the Draft 2030 Countywide General Plan for Yolo County (Yolo County 2008) contains goals, policies, and actions aimed at reducing the risk of flooding within the county. Any violation of these goals, policies, and actions would constitute a significant effect.

Goals

GOAL HS-2: Flood Hazards. Protect the public and reduce damage to property from flood hazards.

Policies

Policy HS-2.2: Ensure and enhance the maintenance and integrity of flood control levees.

Policy HS-2.3: Actively update and maintain policies and programs to ensure consistency with state and Federal requirements.

Actions

Action HS-A4: Require a minimum of 100-year flood protection for new construction, and strive to achieve 200-year flood protection for unincorporated communities where such levels of protection are not provided, require new development to adhere to the requirements of state law and the County Flood Damage Prevention Ordinance.

Action HS-A13: Require a minimum 50-foot setback for all permanent improvements from the toe of any flood control levee.

Action HS-A15: Support the efforts of levee maintenance districts with efforts to secure state and federal funding for geotechnical studies of levees and implementation of associated improvements.

Action HS-A16: Encourage flood hazard reduction projects along the Sacramento River to be consistent with the guidelines of the Sacramento River Corridor Floodway Management Plan.

Action HS-A17: Coordinate with local, state, and federal agencies to define existing and potential flood problem areas, including the possible effects associated with global climate change, and to maintain and improve levees and other flood control features.

Action HS-A18: Develop a detailed maintenance and funding plan for levees under County control, to ensure that levee safety is maintained.

Action HS-A19: Support and encourage responsible agencies to site new levees or major rehabilitation of levees at a distance from the river and from existing levees, where feasible. This would provide a degree of redundancy in the system, increase the land available for habitat and flood storage, reduce operation and maintenance costs, and help to ensure the integrity of the structures.

Action HS-A21: Ensure that the upgrade, expansion, or construction of any flood control levee demonstrates that it will not significantly divert flood water or increase flooding.

Action HS-A23: Improve the county's classification within the Federal Emergency Management Agency Community Rating System.

Action HS-A28: Pursuant to Section 8201 of the State Water Code, develop local plans for flood protection, including analysis of financing options to construct and maintain any needed improvements, to address how 100-year floodplain protection for each community may be provided. Those communities that are economically disadvantaged shall have priority in developing flood protection plans. The cities shall be consulted in development of the plans, which shall be consistent with the Central Valley Flood Protection Plan.

Solano County

The Public Health and Safety Chapter of the Solano County General Plan (Solano County 2008) contains goals, policies, and implementation programs aimed at reducing the risk of flooding within the County. Any violation of these goals, policies, and implementation programs would constitute a significant effect.

Goals

HS.G-1: Minimize the potential for loss of life and property resulting from natural or human-caused hazards.

HS.G-5: Recognize the multiple functions of the natural environment for safety, recreation, protection from climate changes, and economic uses.

Policies

HS.P-2: Restore and maintain the natural functions of riparian corridors and water channels throughout the county to reduce flooding, convey stormwater flows, and improve water quality.

HS.P-6: Work with federal, state, and local agencies to improve flood control and drainage throughout the county.

HS.P-8: Work with responsible parties to ensure dams, levees, and canals throughout the county are properly maintained and/or improved.

HS.P-10: Ensure that flood management policies that minimize loss of life and property also balance with environmental health considerations of the floodplain and therefore do not cause further erosion, sedimentation, or water quality problems in the floodplain area.

Implementation Programs

HS.I-5: Require periodic stream maintenance by private property owners, and undertake regular stream maintenance by the appropriate public agencies.

HS.I-6: Continue to make regular flood control and drainage improvements as recommended by local agency plans, the U.S. Army Corps of Engineers, and the California Reclamation Board. These actions are independent of and in addition to the development review process.

HS.I-7: During project review, require the use of stormwater management techniques in developed upstream watershed areas that protect low-lying areas from flooding. Incorporate appropriate measures into the development review process to mitigate flooding and prevent erosion in and around county ditches.

HS.I-10: During project review, encourage the use of landscaping practices and plants that will reduce demand on water, retain runoff, decrease flooding, and recharge groundwater.

HS.I-13: Work with the Solano County Water Agency to create a countywide comprehensive flood management plan.

HS.I-15: Work with the Solano County Water Agency (or successor agency) in preparing a hydrological analysis of uplands, identifying the different watersheds that drain into the county, establishing flood-related objectives and priorities on a study area basis, and translating those into a coordinated series of flood-preventive measures for each watershed.

City of West Sacramento

The Central Valley Flood Protection Plan (CVFPP) requires 200-year flood protection by the year 2025. The time and effort required to fully evaluate approximately 50 miles of levees, and develop recommended strategies for improvement, and implement those improvements prompted action without further delay. In addition, within its General Plan, the City adopted a goal of achieving 200-year flood protection.

The Health and Safety Section of the City of West Sacramento General Plan, Policy Document (City of West Sacramento 1990) contains goals and policies aimed at reducing the risk of flooding within the county. Any violation of these goals and policies would constitute a significant effect.

Goals

Goal B: To prevent loss of life, injury, and property damage due to flooding.

Policies

Policy 1: The City shall continue to participate in the National Flood Insurance Program. To this end, the City shall ensure that local regulations are in full compliance with standards adopted by the Federal Emergency Management Agency.

Policy 6: Construction of storm drainage improvements shall be required, as appropriate, to prevent flooding during periods of heavy rainfall.

Policy 8: The City shall cooperate with area reclamation districts and other responsible agencies in the maintenance and improvement of levees and drainage channels.

Policy 9: The City shall support state and federal legislation which provides funding for the construction of flood control improvements in urbanized areas.

Policy 10: The City shall discourage uses that promote the erosion or structural deterioration of levees.

West Sacramento Area Flood Control Agency

WSAFCA is proposing the WSLIP to improve the levees in Yolo and Solano Counties that protect the city of West Sacramento. WSAFCA is a Joint Powers Authority created in 1994 through a Joint Exercise of Powers Agreement by the City, Reclamation District (RD) 900, and RD 537. WSAFCA was established to coordinate the planning and construction of flood protection facilities and to finance the local share of flood control projects. WSAFCA is responsible for the operations and maintenance of the detention basins, pump stations, and levees that protect the city.

WSAFCA Freeboard Requirements for Proposed Program Area

WSAFCA has no minimum freeboard requirements. Because USACE is the NEPA lead agency for the WSLIP, and the overall intention of the WSLIP is to provide protection for the 200-year flood event, WSAFCA uses the minimum freeboard requirements set forth by USACE.

3.2.2.2 Environmental Setting

3.2.2.2.1 Flood Control

Sacramento River Flood Control Project

The Sacramento River Flood Control Project (Flood Control Project) was authorized by Congress in 1917. The Flood Control Project was the major project for flood control on the Sacramento River and its tributaries. It was sponsored by The Reclamation Board of the State of California (today reauthorized as the CVFPB) and was the first Federal flood control project constructed outside the Mississippi River Valley (U.S. Army Corps of Engineers 2009a).

The Flood Control Project includes approximately 980 miles of levees, overflow weirs, pumping plants, and bypass channels. Currently, the Flood Control Project extends from the Sacramento River's mouth near Collinsville in the Delta to near Chico Landing in the northern Sacramento Valley. Approximately 980 miles of levees were constructed as part of the project, providing flood protection to roughly 800,000 acres of highly productive agricultural lands, the cities of Sacramento and Marysville, and numerous other small communities. Although the Flood Control Project levees often were constructed of poor foundation materials such as river dredge spoils that would not meet current engineering standards, the levees are relied upon to provide flood protection during major storms to more than 2 million people in approximately 50 communities with an estimated $37 billion in urban and agricultural development.

For more information about the Flood Control Project and related programs and actions, refer to Chapter 1, Introduction.

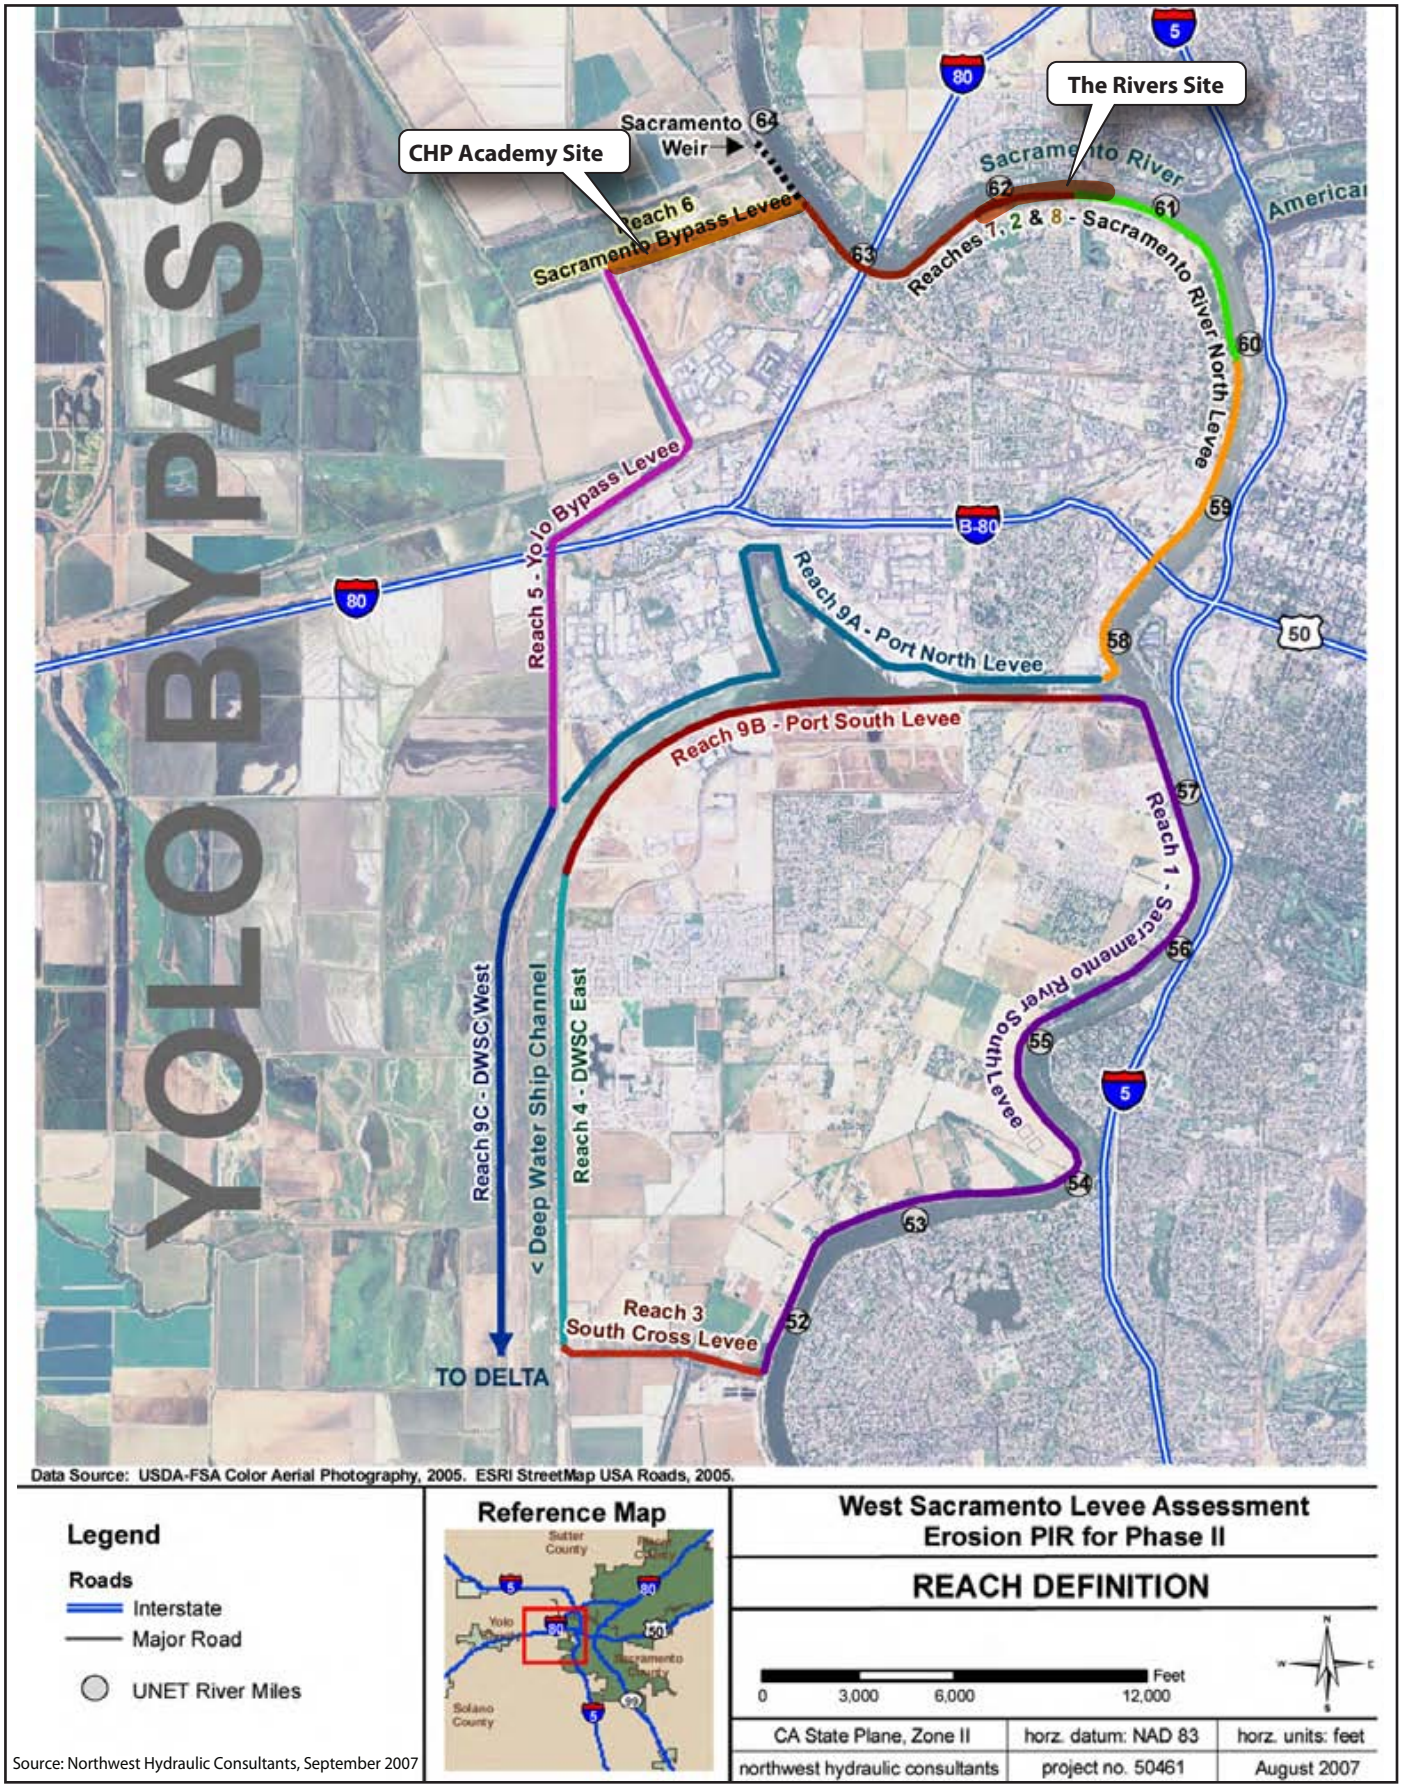
3.2.2.2.2 Climate

West Sacramento has a mild, Mediterranean-type climate. Mean annual temperature is a relatively mild 62.2°F. Maximum average annual temperatures during the summer range from 87.1°F to 93.1°F. Temperatures sometimes exceed 100°F. Winter temperature maximums vary from 54.5°F to 60.6°F. Average low temperatures in the winter range from 40.2°F to 43.7°F. Temperatures in the winter only occasionally drop below freezing. (Andrews 1972.)

Average annual precipitation is about 18 inches, with approximately 80% of the total rainfall occurring between November and March. Cloud-free skies generally prevail throughout the summer months, and in much of the spring and fall. Thunderstorms are relatively infrequent, although occasionally occur in the late summer and other times of the year when unstable air masses are situated over the region. The highest rainfall generally occurs in January, when the average is about 4.2 inches of precipitation. The driest month is July, during which rainfall is rare.

The temporal variability in precipitation is related to seasonal variation in atmospheric conditions. During the summer months, high pressure systems build over the Pacific Ocean off the California coast, promoting the transport of cool, dry air from the north. This effectively blocks major sources of moisture. During the winter rainy season, the jet stream migrates farther south, allowing low pressure systems off the California coast to create conditions that transport moisture inland. Extreme variability of rainfall averages is indicative of wet and dry cycles. During Water Years 1986, 1993, 1995, 1996, and 2005, total rainfall was significantly higher than normal, with annual precipitation measured at 30.15, 29.41, 24.79, 23.74, and 19.95 inches, respectively[2] (California Department of Water Resources, Office of Water Use Efficiency, California Irrigation Management System 2009). Recent dry periods include the 1976–77 and 1987–1992 drought years, with precipitation far below average because of the prevalence of stable, high pressure systems during those winter months.

3.2.2.2.3 Hydrology and Hydraulics



Naming Conventions

Two naming conventions have been adopted for the West Sacramento Levee system. Initially, the system was divided into 11 numbered reaches (Reaches 1–9), including 9A, 9B, and 9C, around the Port of Sacramento and the DWSC. The numbers subsequently were replaced with names, and some reaches were combined, resulting in nine named reaches (Figure 3.2-1). Northwest Hydraulic Consultants (NHC) further combined the levee reaches surrounding West Sacramento into three broad groups for their erosion assessment (Northwest Hydraulic Consultants 2007a). The Affected Environment section of this chapter uses these three broad groups for descriptive purposes.

The first group is reaches 1, 2, 7, and 8 along the Sacramento River, extending from the southern boundary of West Sacramento upstream to the Sacramento Weir. These are further described below:

- Sacramento River South Levee (Reach 1): 6.4 miles of the right (west) levee along the Sacramento River from the South Cross Levee upstream to the Barge Canal, and

[2] Measurement recorded at Station # 6 in Davis, CA (38°32'09"N / 121°46'32"W).

00875.07 EIS/EIR (8-09)

Figure 3.2-1
Reach Definition

- Sacramento River North Levee (Reaches 8, 2, and 7): 6.0 miles of the right (west) levee of the Sacramento River from the left (north) bank of the Barge Canal upstream to the left (south) levee of the Sacramento Bypass (Reach 6).

The second group is reaches 5, 6, and 9c along the Sacramento Bypass South Levee and the levees along the east side of the Yolo Bypass. These are further described below:

- Sacramento Bypass Levee (Reach 6): 1.2 miles of the left (south) levee of the Sacramento Bypass from the Sacramento River to the left (east) levee of the Yolo Bypass,
- Yolo Bypass Levee (Reach 5): 3.8 miles of the left (east) project levee of the Yolo Bypass from the left (south) levee of the Sacramento Bypass to the DWSC West Levee, and
- DWSC West Levee (Reach 9C): Approximately 21.5 miles of the navigation levee between the Yolo Bypass and the DWSC that controls flood levels in the Port of Sacramento. Both the west and east sides of the DWSC levee are discussed as part of this group.

The third group is reaches 3, 4, 9A, and 9B along the DWSC, the levees around the Port of Sacramento, and the remaining reaches on Figure 3.2-1, as described below:

- DWSC East Levee (Reach 4): 2.8 miles of the left (east) levee of the DWSC levee extending south of the Port of Sacramento,
- Port North Levee (Reach 9A): 4.96 miles of the north bank of the Port of Sacramento between the left (east) levee of the Yolo Bypass and the locks on the DWSC,
- Port South Levee (Reach 9B): 3.38 miles of the south bank of the Port of Sacramento between the left (east) levee of the DWSC and the locks on the DWSC, and
- South Cross Levee (Reach 3): This levee extends along the southern boundary of West Sacramento, joining Reach 1 and Reach 4. This levee is not regularly exposed to flow and was not included in NHC's erosion evaluation (Northwest Hydraulic Consultants 2007a).

Levee Stationing

Levee stationing is unique to each reach and was provided by HDR, Inc. Where appropriate, the particular baselines and 0+00 stations are shown on figures or described in the various reports. See Figures 3.2-2 and 3.2-3 (HDR, Inc. 2008a) for levee reach stationing.

Regional Hydrology

Rivers flowing into the north Delta convey approximately 50% of the state's annual runoff (California Department of Water Resources 1995). The main river systems are the Sacramento, San Joaquin, Mokelumne, Cosumnes, and Calaveras. All the major rivers are regulated by dams, except for the Cosumnes River. The Sacramento River is the dominant source of fresh water and sediment to the north Delta, accounting for approximately 80% of annual freshwater inflows (Anderson 1994). The San Joaquin River is the second largest contributor, accounting for about 10% of annual freshwater inflows. Delta flows not diverted to agricultural and municipal intakes continue through the Carquinez Strait into the San Francisco Bay Estuary, and eventually through the Golden Gate into the Pacific Ocean.

Principal reservoirs controlling flows in the lower Sacramento River include Shasta Reservoir (4.55 million acre-feet [af]) on the Sacramento River upstream of Redding and Trinity Reservoir (2.48 million af), which regulates deliveries made to the Sacramento River from the Trinity River

basin. Diversions from the Trinity River basin into the Sacramento River basin averaged 1.03 million af annually from 1967 to 1991. The Feather River is a major tributary to the Sacramento River, and Oroville Reservoir is a component of the State Water Project (SWP) system that provides 3.54 million af of storage. Average runoff from the Feather River basin (including the Yuba River) is approximately 5.85 million af at the Nicholas gaging station (downstream of the confluence with the Yuba River).

The Sacramento River drainage basin upstream of the American River confluence encompasses approximately 23,500 square miles. The monthly minimum, average, and maximum mean daily flows on the Sacramento River near Verona (upstream of the American River) and at Freeport (downstream of the American River) are presented in Table 3.2-1. The proposed program area extends down past the American River watershed. The Sacramento River at Freeport gage more closely reflects the actual project flow around the southern end of the proposed program area.

Table 3.2-1. Monthly Mean Daily Flow Statistics for Sacramento River at Verona and Sacramento River at Freeport for 1990 through 2008

	Sacramento River at Verona Station 11425500			Sacramento River at Freeport Station 11447650		
	Minimum	Average	Maximum	Minimum	Average	Maximum
January	6,460	29,888	95,600	6,560	34,311	113,000
February	6,200	34,008	76,300	6,030	39,647	94,100
March	7,730	31,811	80,700	8,300	36,793	99,500
April	3,920	22,552	73,600	4,340	26,786	91,800

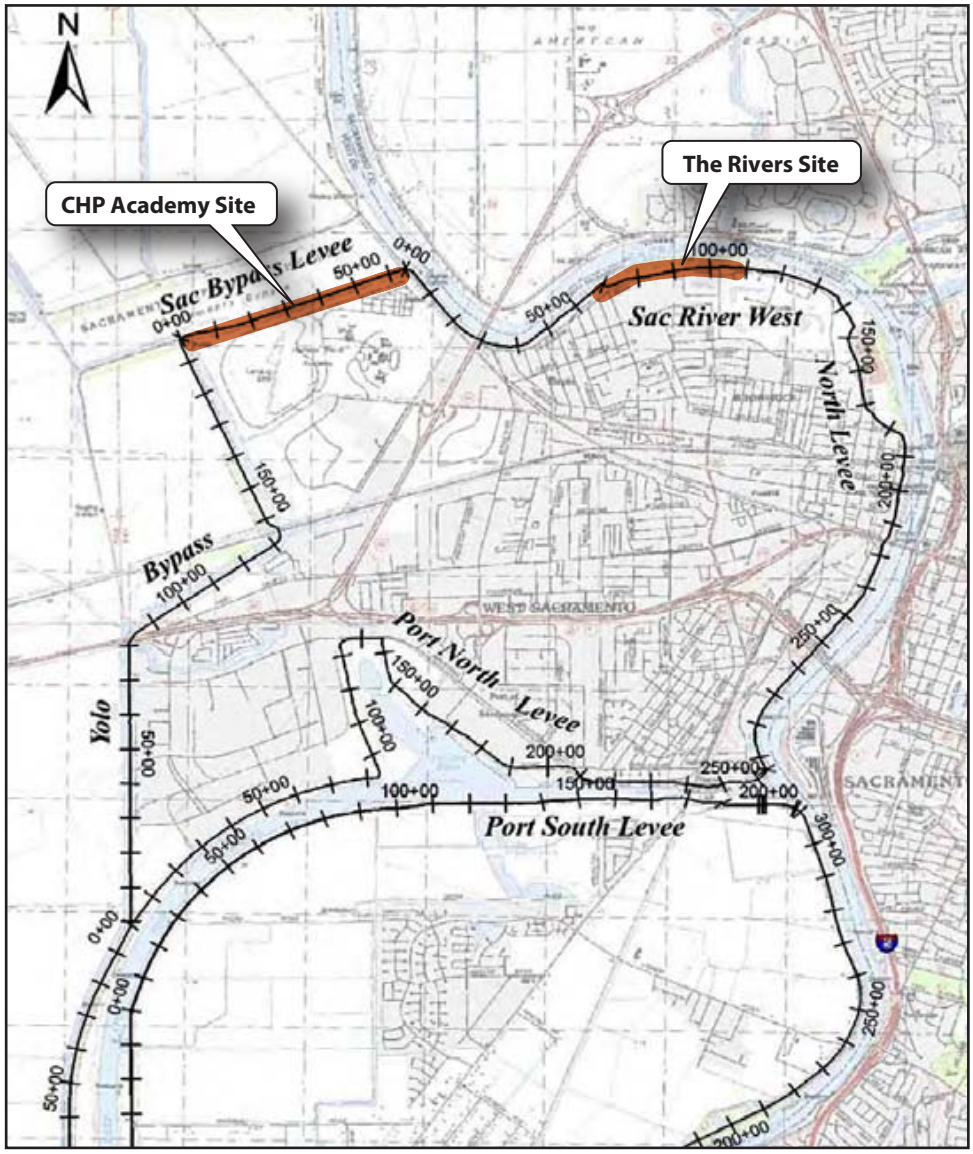
Notes: Flow in cubic feet per second from January 1, 1990 to February 8, 2009.

All hydrologic information described below for the three groups of levees under investigation is derived and summarized from NHC (2007a).



Sacramento River Sites (Sacramento River North and South Levees—Reaches 1, 2, 7, and 8)

Daily streamflows have been recorded at the Sacramento River at Verona gage (gage 11425500) by the U.S. Geological Survey (USGS) since 1929. The gage is upstream of the proposed program area, at approximately RM 78.6. The Sacramento River at Sacramento (I Street) gage (gage 11447500) was operated by USGS from 1948 to 1979; it is now operated by DWR. The gage is located about 1,000 feet upstream of the I Street Bridge and about 0.5 mile downstream of the American River confluence at RM 59.5 in Reach 8. The Freeport gage (gage 11447650) is downstream of the

Figure 3.2-3
West Sacramento Northern Basin - Levee Reach Stationing

proposed program area, at about RM 46. NHC (2007b) provides a detailed analysis of daily, seasonal, and peak flows at the I Street and Freeport gages.

Projected peak flows in the Sacramento and American Rivers were provided by MBK Engineers (2008a) based on the Sacramento and San Joaquin River basins California Comprehensive Study (Comprehensive Study) Sacramento River UNET model. In Table 3.2-2, the 100-year projected peak flow is based on a 145,000 American River peak flow and upstream Sacramento River levees overtopping without failing; the 200-year peak is based on 160,000 cubic feet per second (cfs) American River peak flow and the same levees overtopping without failing. See section on Flooding below for longitudinal profile information with resulting maximum water surface elevation profiles (for the 1/100 and 1/200 Annual Exceedance Probabilities [AEPs]), the approximate tops of the levees, and the original 1957 Flood Control Project design floodplain for the Sacramento River, Sacramento Bypass, Yolo Bypass, and DWSC.

Table 3.2-2. Projected Peak Flows for Sacramento River Sites

	Projected Peak Flow (cfs)	
Location	100-year[1]	200-year[2]
Sacramento River at Verona Gage	117,500	142,600
Sacramento River at I Street	135,600	143,300
Sacramento River at Freeport Gage	135,200	143,000
American River at H Street	145,000	160,000

[1] Assumes levees overtop without failing; existing conditions and operations.

[2] Assumes levees overtop without failing; urban levees have three feet of freeboard on 1/200 AEP water surface; non-urban levees satisfy SRFCP design freeboard requirements; Folsom Dam Joint Federal Project in place.

Yolo and Sacramento Bypass Reaches (Yolo Bypass Levee, Sacramento Bypass Levee, and Deep Water Ship Channel West Levee—Reaches 5, 6, and 9C)

Flows in the Yolo Bypass come from several different sources. Floodflows from Sutter Bypass and the Sacramento River enter the Yolo Bypass over the Fremont Weir when the stage in the Sacramento River reaches 32.27 feet in the North American Vertical Datum of 1988 (NAVD 88).

Water also enters the Yolo Bypass from the west side tributaries—Knights Landing Ridge Cut, Cache Creek (Cobble Weir), Willow Slough Bypass, and Putah Creek—and from the Sacramento Weir. The gates of the Sacramento Weir are opened when stages exceed 30.07 feet (NAVD 88) at the I Street Bridge: the weir operates infrequently. Various documents describe the relative importance of these sources of floodflows (Yolo Bypass Working Group 2001; Natural Heritage Institute 2003).

DWR has maintained a gage at Lisbon Weir, along the Yolo Bypass Levee, since 1935. Water levels at this gage are tidally influenced and fluctuate between 3 and 7 feet stage (USACE datum) or between 3.07 and 7.07feet NAVD88, at low water. Flood stage at the gage is 11.5 feet (11.57 feet NAVD 88); above this elevation water is no longer contained in the Toe Drain and the Yolo Bypass starts to inundate. The Yolo Bypass floods about 3 out of 5 years, on average, and the annual duration of flooding ranges from zero to 135 days.

The maximum stage recorded at the Lisbon Weir was 27.47 feet NAVD 88 in February 1986. The maximum stage in January 1997, 24.6 feet, was slightly lower than in 1986, but the maxima in these two years are several feet higher than in the other years of record (Jones & Stokes 2006). Water surface elevations in these years were only 2 to 3 feet below the top of the Yolo Bypass levee (U.S. Army Corps of Engineers 2006). Since 1997, USACE has raised levee elevations along the upper portion of the Yolo Bypass Reach and in the Sacramento Bypass by up to 5 feet.

Based on the DWSC West Levee sections in Appendix D of NHC (2007a), a typical elevation for the berm on the Yolo Bypass side of the levee near the Lisbon gage is 17.57 to 22.57 feet NAVD 88. Based on the mean daily water surface elevation duration curve for Lisbon gage in NHC (2007a), stage exceeds this elevation only 2 or 3% of the time, indicating that high water levels that result in wave attack on the levee occur only infrequently.

MBK Engineers provided average cross-sectional velocities in the Yolo Bypass from their UNET model. These velocities varied from 2 to 4 feet/second despite the large cross-sectional area in the bypass. Velocity data at the Lisbon Gage, which is close to the levee, show maximum velocities of about 2.5 feet/second. Velocities vary considerably across the sections and may be higher where flows accelerate around obstacles, around bends, or where the section narrows. (Northwest Hydraulic Consultants 2007a.)

Port of Sacramento and Deep Water Ship Channel East Levees (South Cross Levee, Deep Water Ship Channel East Levee, Port North Levee, and Port South Levee—Reaches 3, 4, 9A, and 9B)

Detailed hydrology and hydraulics information for these reaches is not included in this EIR/EIS. The DWSC and Port levees are essentially backwater channels in which the water surface elevation is controlled/equal to the water surface elevation where the DWSC connects to Cache Slough. A discussion of flooding characteristics for these reaches is provided below in the Flooding section.

3.2.2.2.4 Geomorphic Conditions

The present geomorphic state of the lower Sacramento River basin and the north Delta is a function of the intensity of water management in each of the tributary rivers, local farming practices, intra- and inter-Delta water transfers, and an extensive human-made levee system. Today, channel alignments are largely fixed by artificial levees and erosion control measures. Flooding, except when artificial levees break, no longer occurs on most islands and tracts. Instead, flow and sediment remain confined to the existing channel network. Upstream water diversions for municipalities and agriculture reduce the amount of flow entering the Delta and the amount of sediment transported to the Delta. In addition, conveyance of water within and out of the Delta alters flow directions and affects sedimentation and erosion rates and patterns. The levee system in the Delta restricts flow to a network of human-made and natural channels that reduce flood events and inhibit the accumulation of soils on the Delta islands.

Historic changes in the lower Sacramento River basin and north Delta that have affected channel morphology include land reclamation, levee construction, dredging, hydraulic mining, impoundment of water and sediment by upstream dams and other diversions, and the construction of water diversion facilities and consequent alteration of flow and sedimentation patterns in the Delta. The effects of these changes on channel morphology in the proposed program area are summarized below.

- Waterways in the proposed program area are largely confined by levees and able to convey significantly greater flow and sediment discharges than during historic times.
- Historic cross section data indicate that the majority of waterways in the proposed program area have experienced some channel incision over the several decades and may be experiencing a net sediment loss over time.
- Water regulation, diversions, and the impoundment of water and sediment by dams has resulted in a decline in the total annual water and sediment outflows to the Delta from the Central Valley, a trend that is expected to continue into the future (Northwest Hydraulic Consultants 2003).
- The construction of large water diversion facilities such as the Delta-Mendota Canal and Delta Cross Channel in 1951 and California Aqueduct in 1973 have altered the traditional flow patterns in the Delta that affect sedimentation. Water and sediment exhibit a more southerly flow in the Delta, somewhat reducing deposition of sediment in the north and central Delta and increasing deposition of sediment in the south Delta (Northwest Hydraulic Consultants 2003).
- The combination of overgrazing, deforestation, floodplain reclamation, river channelization, and most importantly, hydraulic mining for gold caused large increases in sediment loads in the Delta system. The historic trend demonstrates a rapid decline of sediment loads in the Delta streams at the beginning of the twentieth century, followed by a gradual, steady increase of sediment loads over the last half century (Northwest Hydraulic Consultants 2003).
- Historically, some deposition of the solids occurred at locations in the Delta channels where water velocities were low. During high-flow periods, a high percentage of these solids were re-suspended and moved downstream toward San Francisco Bay.

For a complete review of the historic geomorphology of the Delta region, refer to NHC's 2006 *North Delta Sedimentation Study.*

Sediment Inputs to the Delta

Most of the sediment supplied to the Delta (between 80% and 85% in an average year) is carried by the Sacramento River, whereas the San Joaquin River and the Mokelumne-Cosumnes River supply only about 10% and 4%, respectively (Northwest Hydraulic Consultants 2003). The remaining sediment enters the system from the Yolo Bypass and from several other smaller tributaries and sloughs. The Sacramento River is a sand-bed river; sediments transported through the action area include sands, silts, and clays.

The Flood Control Project conveys released reservoir waters from various upstream sources and stormwater runoff through the Delta and into San Francisco Bay. These waters contain dissolved and undissolved solids, both of which are transported through the system. Undissolved solids—sediment—consist primarily of clay-, silt-, and sand-sized particles. Before construction of the flood control and conveyance system, the natural flow of freshwater runoff from the upstream mountainous regions transported significant quantities of silt and clay particles. Because of the wide expanse and flat terrain of the proposed program area, these particles would settle and form the sediments of the northern Delta alluvial plain. During the wet season, when the volume of runoff water was much larger, the quantity of suspended and unsuspended solids was significant and included sands and, in some cases, gravels.

The natural processes described above continue today but in a modified manner. Much of the naturally eroded and transported solid particles now settle out in instream water storage reservoirs.

A percentage of the fine solids, like silts and clays, still are transported during water releases that enter the system from waterways downstream of the reservoirs. These sediments enter the Delta channels, and rather than settling out in the alluvial plain (as occurred before the channels were constructed), they now remain within the leveed channels.

For a description of total suspended sediment and turbidity see Section 3.3, Water Quality and Groundwater Resources.

Geomorphic Characteristics of the Study Area

Because of the low topographic position and proximity to the confluence of the Sacramento and American Rivers, the proposed program area has been subjected to repeated inundation by floodwaters during late Holocene time, and consequently is underlain by relatively thick alluvial deposits. The surface and subsurface distributions of sandy and clayey deposits are a function of former river alignments on the landscape, and present-day geomorphic processes adjacent to the river channels (i.e., flooding and deposition). In brief, the primary geomorphic features and associated surficial geological map units in the proposed program area include abandoned paleochannels, meander scroll deposits, crevasse splay and overbank flood deposits, flood basin deposits, and other features commonly associated with large, active river systems. (William Lettis & Associates 2007.)

The current geomorphology of the proposed program area is characteristic of Delta waterways. All waterways are bordered by levees. Channel alignments are preserved by ongoing levee maintenance and instream dredging. The Sacramento River in the vicinity of the proposed program area is characterized by a low gradient and typical low-velocity flow and is composed almost entirely of deep flatwater with a sand bed. River stage is controlled by dam and weir release upstream and is subject to diurnal tidal fluctuation. Very little sediment is stored in bars, and the bank-building process typical of lowland alluvial rivers no longer occurs. The channel width varies in the proposed program area but averages approximately 750 feet.

All geomorphic information described below (descriptions of hydraulic geometry, levee and bank geometry, and channel morphology) for the three groups of levees under investigation is derived and summarized from NHC (2007a). The overall goals of the NHC (2007a) report were to (1) identify those sites in the proposed program area where erosion occurs and without intervention may significantly compromise the flood performance and integrity of the levee system, (2) assess the risk of erosion at these sites and determine whether repairs are required for FEMA certification, and (3) provide feasibility or concept level erosion protection alternatives for those sites where protection is required for certification.

Sacramento River Sites (Sacramento River North and South Levees—Reaches 1, 2, 7, and 8 of the West Sacramento Levee System)

Hydraulic Geometry

The hydraulic geometry or hydraulic properties of the West Sacramento reach of the Sacramento River are based on analysis of cross sections on 0.25-mile spacing along the Sacramento River South Levee, as obtained from MBK's UNET model. The hydraulic geometry is based on a bankfull geometry interpreted from the cross sections and the 200-year projected peak flow geometry, calculated from the water surface elevations reported by the UNET model. This information is described in further detail in NHC's internal report *West Sacramento Erosion Site, Design Scour*

Levels for Erosion Protection (Northwest Hydraulic Consultants 2007c). Table 3.2-3 shows the geometry at the erosion sites for the 100- and 200-year AEP water levels, as interpreted from the nearest cross section. The geometric properties of the Sacramento River through West Sacramento are as follows:

- Average surface width at natural bankfull conditions — 570 feet
- Average bed width, excluding one triangular section — 340 feet
- Average bankfull depth, averaged over 19 sections — 39 feet
- Average bankfull cross-sectional area — 17,400 square feet
- Range of maximum depths below 200-year water level — 49 to 92 feet

Table 3.2-3. Hydraulic Geometry at the Erosion Sites

[1] River Mile to middle of site.

[2] River Mile to upstream end of site.

[3] Interpolated from nearest cross section.

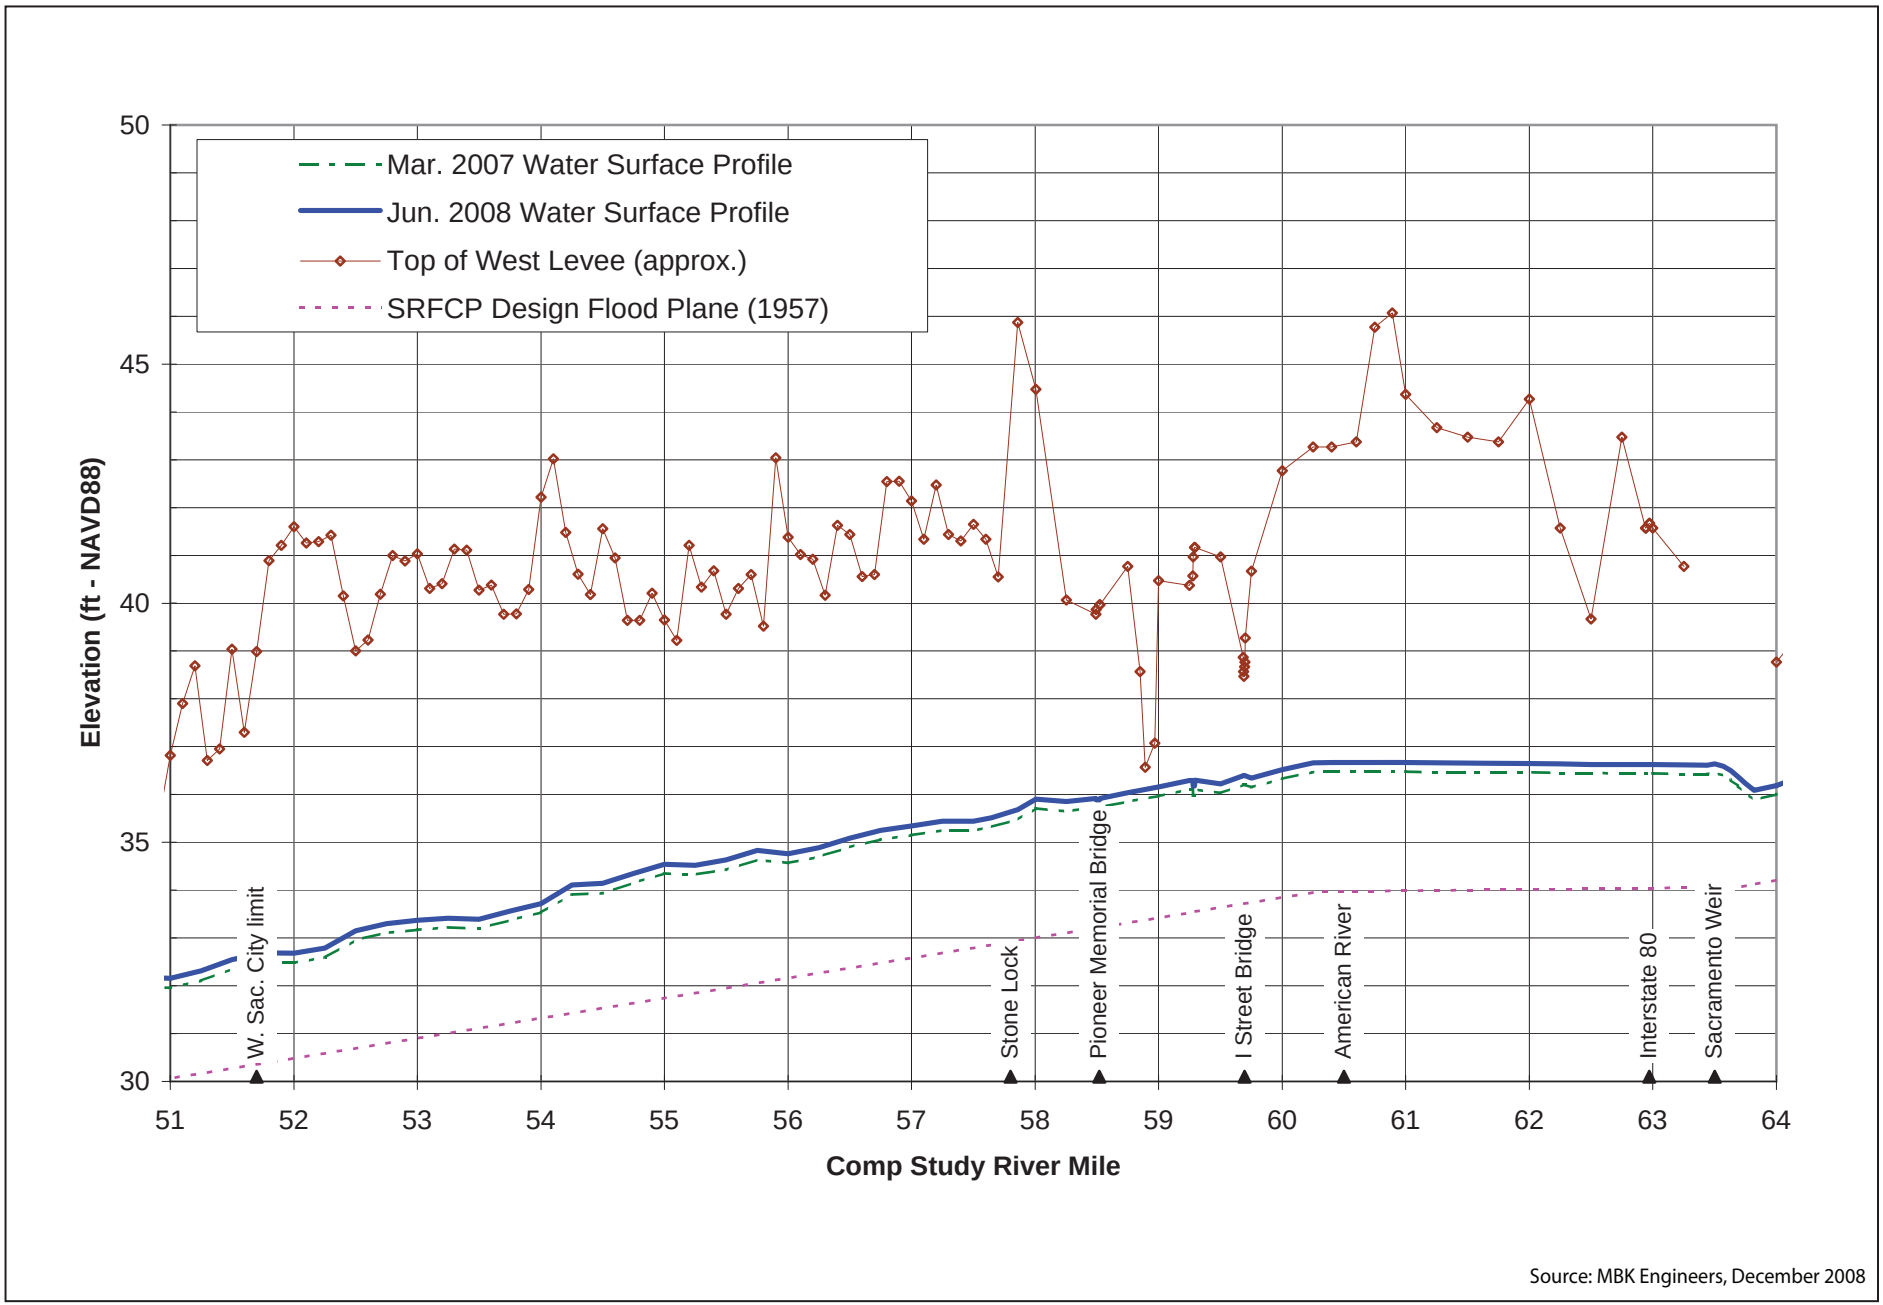
The 200-year discharge at I Street is 143,300 cfs (Table 3.2-2). At the Freeport gage about 10 miles downstream, the maximum recorded discharge over the past 50 years was just less than 120,000 cfs, in 1986. The computed 200-year water surface slope for the West Sacramento Reach is approximately 0.53 ft/mile (0.10 meters/kilometer [m/km]).

Assuming a Manning roughness n-value of 0.030, the cross-sectional average velocity under bankfull conditions is estimate at about 4.6 feet per second (ft/s), resulting in an estimated bankfull discharge of about 80,000 cfs. Based on the cross sections provided by MBK Engineers, during the 200-year flood the average channel velocity in the West Sacramento Reach is about 5.1 ft/s (Table 3.2-3), and the average cross-sectional area is about 25,500 square feet (ft^2), giving a

calculated discharge of about 138,000 cfs, essentially equal to the value of 143,300 cfs provided in Table 3.2-2.

The section-averaged velocities during the 200-year projected peak flow do not present a significant concern for surface erosion by flows parallel to the bank, except where the banks have no vegetation and no other bank protection or where significant obstructions project into the flow and generate eddies and complex flows capable of eroding the stream bank. In most cases velocities along the bank will be lower than the section averages but may be near the average or slightly above along the outside (concave) bank of tight bends.

Levee and Bank Geometry



West Levee of the Sacramento River

The earliest maps along the Sacramento River, from 1908, show a levee on about the same alignment as at present, along the top of the west bank of the Sacramento River. This levee has been raised, widened, upgraded, and set back at some sites over the years. The Sacramento River South Levee crest is now between 17 and 23 feet high above the landside toe, with crown elevations between 34 and 40 feet. South River Road lies along most of the levee crest, and crest widths are usually just larger than the minimum of 20 feet. Kleinfelder (2007) discusses the stability berms, drains, and other remediation measures constructed along this leveed reach.

Kleinfelder (2007) also describes the levee soils and underlying foundation materials based on borings. The levee soils are typically silty sand and poorly graded clean sand. Beneath the levee materials, the typical profile consisted of a layer of fine-grained silt or clay (interpreted to be overbank deposits) underlain by up to 100 feet of sand and gravel, with interbedded silty sand and clayey sand layers. The main exception to the above typical profile is near the downstream end of the South Levee reach, where the levee is on an old railway grade. Drilling here showed a blanket of silt and clay extending at least 20 feet below the levee materials underlain by sand and/or gravel. These were interpreted to be floodbasin deposits, which appear to extend into the stream bank, overlying alluvium. The bottom of the flood basin deposits is at or above the thalweg elevation of the Sacramento River. The presence of these less-erodible deposits is thought to explain the straight, stable bank and narrow river section through the Clay Bend just near the downstream end of the South Levee reach.

Crest elevations along the Sacramento River North Levee (Reaches 8, 2, and 7) range from 36.57 to 46.57 feet NAVD 88 (Figure 3.2-4). Reach 8, the most downstream section of the North Levee, includes high ground that extends from the Barge Canal upstream to the Tower Bridge. The high ground is as high, or higher, than adjacent levee crests and extends at least 300 feet landward (Jones & Stokes 2006). The high ground appears to be stable and generally consists of river dredge spoils placed more than 75 years ago. Bank erosion was observed along this part of Reach 8, but it is not a concern for levee failure as the high ground functions as a very wide levee. From the Tower Bridge toward the I Street Bridge, the levee has been set back and protected as part of the River Walk project. However, the upstream 2,000 feet of Reach 8—near the I Street Bridge—has a minimum crest width and sparse bank protection and is close to the river. The erosion sites in Reach 8 are in this section of the Sacramento River North Levee.

In the middle of the Sacramento River North Levee (Reach 2), bank erosion was observed primarily where the levee crest appears to be extremely wide or where there is a substantial berm to protect the levee. From the upstream end of Reach 2, downstream for about 4,000 feet, revetment of varying

Source: MBK Engineers, December 2008

00875.07 EIS/EIR (03-10) AB

Figure 3.2-4
Maximum Water Surface Elevation, Sacramento River

size and age has been placed on the bank and levee. This revetment is often extremely steep and does not appear to meet current sizing criteria. For the next 4,000 feet, Reach 2 has some erosion protection. The patches of existing revetment do not appear to be engineered; however, the materials on the bank are often reasonably large and the revetment appears to provide adequate protection against erosion.

The upstream end of the Sacramento River North Levee (Reach 7) includes both riprap-protected banks and wide levee crests. Downstream from the Sacramento Weir for about 7,000 feet, streambanks are generally steep; however, most are either adequately protected with riprap or the levee crest is wide. (This section includes USACE Emergency Levee Repair project at site 62.5R). At the downstream end of Reach 7, and extending for about 3,000 feet, a private contractor designed and built bank protection in the summer of 2006.

Waterside Slope Levees

Through part of West Sacramento, the Sacramento River West Levee sits on or near the top of the bank, and water side levee slopes are often steeper than 3:1. This is particularly true along the South Levee, where the levee crown is near the minimum width, and eroding banks often lie well within the 3:1 waterside levee template.

Along the South Levee, NHC (2007a) evaluated where slopes are steeper than 3:1 by analysis of the bathymetric and topographic maps provided by MBK Engineers (see also HDR, Inc. 2006). This analysis was completed in AutoCAD by drawing a line sloped at 3:1 from the hinge point at the levee crown (edge of road) to the intersection with the existing river bank or bed. A band then was drawn along the bank that indicates the vertical distance between the template and the actual bank. Negative distances indicate that the bank lies inside the template and, therefore, that the observed bank slope is steeper than 3:1. Figures 3-2 and 3-3 of NHC 2007a show the results for Reach 1.

In general, the slopes on the waterside of the Sacramento River South Levee reach are steeper than 3:1, and in some cases are nearly 1.5:1. Excluding Sites 1E and 1H, the erosion sites are all where the existing bank lies well inside the 3:1 design waterside levee template. As discussed in the following section, a large portion of the steep slopes shown on Figures 3-2 and 3-3 of NHC 2007a are covered by riprap revetment and were assumed to be reasonably stable for the purposes of the feasibility-level erosion assessment. The implications of these steep slopes for the geotechnical and civil engineering assessments for FEMA certification are discussed further in Kleinfelder (2007) and HDR, Inc. (2006).

The Sacramento River North Levee has long sections of high ground and over-sized levees and the above analysis is less useful because of the difficulty in defining the appropriate hinge point for the projected waterside levee slope. Instead, Figures 3-4 to 3-6 of NHC 2007a provide typical cross sections for the three reaches along the North Levee, showing both the steep bank slopes and the oversized levee sections. (The typical section in Reach 7 is at the Ayres 62.9R erosion site.) As discussed in Section 2 of NHC 2007a, measurements of berm and levee crown widths where bank erosion was observed, rather than an analysis of waterside levee slopes, were relied on to select erosion sites.

Existing Bank Protection

Long sections of the right (west) bank in the West Sacramento reach are protected, commonly by revetments constructed of quarry rock (riprap), cobble, or concrete rubble. Figures 3-7 through

3-11 of NHC 2007a show the extent of revetment on the right bank of the North and South Levees and also classify the height of the revetment and cover for the rock types included in the USACE database. About 72% of the total bank along the South Levee is protected by riprap, with most protection in the "greater than 20-inch rock" class. Given the riprap gradations discussed below, this class likely refers to the maximum observed size. About 64%, 30%, and 44% of the total bank is protected in Reaches 7, 2, and 8, respectively. The majority of the revetment in Reach 7 consists of rock between 12 and 20 inches, while in Reaches 2 and 8 the revetment is composed mainly of rubble greater than 20 inches. These percentages and rock sizes have not been updated to include the bank protection constructed as emergency levee repairs.

The dates the bank protection works were constructed and dates of significant repairs are not well known. The Supplement to Standard Operation and Maintenance Manual for the Flood Control Project Unit No. 116, from 1955, provides the earliest information on erosion protection constructed to bring levees built by local interests to project standards (Table 3.2-4). The table and a review of historic air photos show that revetment had been constructed by the late 1930s at a number of sites, such as along the railway grade at the downstream end of the South Levee.

Source: Northwest Hydraulic Consultants 2007a.

Since 1955, additional bank protection has been constructed, and the earlier revetment repaired, by DWR, USACE, and RD 900. Much of the existing revetment was constructed in the 1960s, but repairs have occurred as recently as the late 1990s (Northwest Hydraulic Consultants Inc. 2007a.). Design drawings or as-built drawings for the revetments constructed in the 1960s have not been located and were not reviewed for this study. Design drawings are available for the protection constructed for the Emergency Levee Repair Program.

Inspection of the South Levee riprap revetments (Northwest Hydraulic Consultants 2007b) showed that they typically were placed on a slope graded to 2:1. The rock usually extended up the slope to elevations of about 30 feet and often was covered by soil at the highest elevations. Wading at low water levels revealed that the existing revetments extended several feet below the fall water line, to at least 15 to 20 feet from shore. It is not known whether the riprap extends farther from the water line or whether a toe was provided for scour protection at the older sites (construction drawings showing a toe are available for the Emergency Works at RMs 56.1, 56.8, and 62.5). Site inspection showed frequent small slumps and loss of material above low water elevations along the older revetments, apparently from boat wave erosion.

Riprap gradations were measured at four sites along the South Levee and showed median weights between 25 and 50 pounds (Northwest Hydraulic Consultants 2007b). Maximum weights were 150 to 200 pounds and the overall gradations were roughly equivalent to those commonly recommended in the 1960s and 1970s (U.S. Army Corps of Engineers 2006). Existing gradations typically are smaller than the new grading recommended in USACE (2006), particularly at the coarse end of the distribution.

Channel Morphology

Channel Planform

The planform of the lower Sacramento River can be described as generally sinuous, with a mix of irregular, partly entrenched meanders and nearly straight reaches. Meander wavelengths and amplitudes are highly variable, with tight bends along the South Levee, but the width of the channel is consistent except at a few bends. The channel is controlled in many places by bank protection, levees, and resistant outcrops so that lateral migration rates are low.

Historic Dredging and Maintenance

The original Sacramento River shallow-draft channel project was authorized by the River and Harbor Act of March 3, 1875, and as modified in 1882, 1889, and 1892. It provided for improvement of low-water navigation by dredging the Sacramento River to provide a depth of 7 feet, by snagging and construction of temporary wing dams in the Feather River, repairing damages caused by floods, and removing obstructions in the lower Sacramento River (U.S. Army Corps of Engineers 1960). Construction of the shallow-draft 7-foot channel downstream of Sacramento began in 1899 and was completed in 1904.

Improvements to the shallow-draft channel were authorized by the River and Harbor Act of March 3, 1899, and as modified in 1912, 1927, and 1935. WET (1990) estimated that, by 1940, about 186 million cubic yards of sediment had been dredged from the Sacramento River downstream of Sacramento. Major channel maintenance activities ceased in the early 1970s as hydraulic mining debris effects lessened and river transportation needs diminished and environmental concerns associated with dredging moved to the forefront.

Channel Bathymetry

It is documented that bed levels in the lower Sacramento River aggraded substantially, as a result of inflows of sediment derived from hydraulic mining in the Sierra Nevada (Alder 1980; James 1989, 1991). Hydraulic mining operations ceased in the 1880s, and sediment loads to the river were greatly reduced. Subsequently, a degradation or incision of the river bed occurred during the first half of the 20th century. In the second half of the 20th century, some bed degradation and channel widening may have continued, in part as a result of trapping bed sediment and control of the natural flow hydrograph by the upstream reservoirs.

Figure 3-12 of NHC 2007a presents thalweg profiles (the lowest point in the channel invert) for 1908, 1933, and 1997 extending from RM 65 (upstream of the Sacramento Weir) to RM 50 in USGS river miles (upstream of the Freeport gage). In brief, the proposed program area has several sites that experience local scour at bends and narrow channel sections (Tables 3.2-5 and 3.2-6). Additional information is provided below in the Projected Incision and Scour Estimates and Erosion Mechanisms discussion.

Table 3.2-5. Thalweg Depths in 1997 at Three Bend Locations

River Mile	Depth Below Upper Thalweg Envelope[1] (Feet)	Depth Below 200-Year Water Surface (Feet)	Description of Channel Bend
62.3[1]	37	81	Abrupt, 90-degrees
54.5 (1I)[1]	50	91	Abrupt, >90-degree
53.8 (1J)[1]	33	75	Abrupt, >90-degree

Change in Cross Sections near the Eroding Sites

Appendix B of NHC 2007a shows historic cross sections near each erosion site, as constructed from the 1908, 1933, and 1997 river surveys (NGVD 29). The 1908 and 1933 survey section locations are only approximate. The 1908 and 1933 cross section data points were rotated and shifted to best fit the 1997 survey. Some spatial errors result from this process.

Table 3.2-7 summarizes the historic changes observed at the toe of the erosion sites since 1908, as interpreted from the fitted cross sections (Appendix B of NHC 2007a). The most significant toe erosion (incision) occurred at Site 1A, likely in response to channel constriction following construction of the Barge Canal headworks. Sites 1B, 1F, and 1I also show significant incision at the toe of the bank.

Table 3.2-7. Cross Section Changes at the Toe of the Eroding Banks

Erosion Site	Net Change in Bed Near Toe of the Bank (Feet)[1]	Comment
1A	-35	Occurred since 1933; likely in response to works associated with barge canal
1B	-20	As above
1C	About zero	
1D	-10	Bed lowering occurred from 1908 to 1933
1E	-8	Occurred since 1933
1F	-15	Occurred since 1933
1G	-12	Occurred since 1933
1H-1/1H-2	+20	Considerable aggradation and growth of bar and berm into the channel
1I	-20	Incision of thalweg at toe of bank
1J	Unknown	Uncertainty with the 1933 cross section
8K	+8	Uncertainty with the 1933 cross section
8L	-7	Occurred since 1933
8M	-5	Occurred since 1933

Source: Northwest Hydraulic Consultants 2007a.

[1] As interpreted for 1908 to 1997 from Appendix C of NHC 2007a; "-" changes are incision; "+" changes are aggradation.

Historic Bank Retreat

Historic bank erosion/channel migration was assessed at each site by comparing air photos from 1938, 1965, 1972, 1982, 1986, 1993, and 2002 (Appendix C of NHC 2007a). Air photos were geo-referenced in GIS and a common reference point—South River Road along the South Levee—was used to measure lateral bank shift from year to year. The bank line was defined as the water's edge along the base of the bank.

Table 3.2-8 shows the bank line shifts calculated at the Reach 1 and Reach 8 sites. Erosion occurred at sites 1A, 1C, 1E, 1I, and 8L at average annual rates between 0.3 and 1 foot/year from 1986 to 2002. Erosion at Site 8L has continued at about the same rate since 1964. The observed erosion is thought to be real and not attributable to errors resulting from comparing the photos. The magnitude of the erosion also is consistent with the bank retreat interpreted from the timber piles that are present at some sites.

Sites 1B, 1D, 8K, and 8M showed no net change in bank alignment from 1986 to 2002. Site 1F, 1G, 1H, 1J, and 8K showed accretion from 1986 to 2002. Sites 1G, 1H, 1J, and 8K are all located on the inside bank of stream bends, where there is a natural tendency for sediment deposition. Site inspections showed accumulation of sand along the lower bank near the summer water line, consistent with the aggradation observed on the air photos.

Table 3.2-8. Historic Bank Line Shifts from 1986 to 2002 and 1964 to 1986

Yolo and Sacramento Bypass Reaches (Yolo Bypass Levee, Sacramento Bypass Levee, and Deep Water Ship Channel West Levee—Reaches 5, 6, and 9C)

Levee and Bank Geometry

Deep Water Ship Channel West Levee (Reach 9C)

The West Levee was constructed as part of the development of the DWSC and the Port of Sacramento. Kleinfelder (2007) provides detail on construction methods. The crest elevation of the West Levee is higher than the DWSC East Levee and it is now the *de facto* Yolo Bypass levee.

The uppermost section of the levee (to station 775+00; called Reach 9C.1 by Kleinfelder [2007]) was constructed about 400 to 600 feet west of the DWSC, except where this levee joins the Yolo Bypass Levee. Where they join is the narrowest section of the DWSC West Levee. Much of the area between the DWSC and the levee included containment levees, berms, and cells to hold dredge slurry. Over time, these have been filled, raising land surface elevations to about the height of the levee crest. Figure 4-7 of NHC 2007a provides a typical cross section, showing about a 5:1 slope on the Yolo Bypass side of the levee, a levee crest width of 20 to 30 feet, and the dredge cells on the DWSC side at an elevation of about 27.57 feet NAVD 88). In this sub-reach, the levee is distant from the DWSC with ground elevations above design water levels in the DWSC (see Chapter 5 of NHC 2007a). In this sub-reach, the DWSC west levee is very unlikely to be eroded by boat waves from the east; instead erosion of the levee is more likely to result from wind waves that develop on the Yolo Bypass during flood stages.

From stations 775+00 to about 1000+00 the DWSC West levee was constructed close to the DWSC, and dredge materials have been placed on the Yolo Bypass side of the levee. Figure 4-7 of NHC

2007a provides a typical cross section in this sub-reach, called Reach 9C.2 by Kleinfelder (2007). Here, there is a broad berm on the Yolo Bypass side of the levee with typical elevations between 12.57 and 17.57 feet NAVD 88. In this sub-reach, the levee is distant from the Yolo Bypass and less likely to be eroded by wind waves that develop on the bypass during flood stages and more likely to be eroded by ship and wind waves on the DWSC. The crest of the levee in the most downstream sub-reach of the DWSC West Levee (called Sub-reach 9C.3) is about 8 feet lower than in Reach 9C.2. This part of the levee is overtopped during large floods and, as a result, erosion of the levee will not raise water levels in the Port of Sacramento during the base flood.

Kleinfelder (2007) describes the levee materials in Reach 9C.1 as primarily clays, with lesser amounts of silt, silty sand, and clayey sand. Foundation materials consist of a blanket of clays and silts up to 35 feet thick, underlain by poorly graded sands and occasional gravel layers. Levee soils in Reaches 9C.2 and 9C.3 are similar to those in Reach 9C.1, and foundation materials consist of clay, silt, and some sand, underlain by poorly graded sand.

Sacramento and Yolo Bypass Levees (Reaches 5 and 6)

The levees in the Sacramento and Yolo Bypass are part of the original Federal project levee built in the early 20th century. Kleinfelder (2007) indicates that this levee originally was constructed by clamshell dredge with the local flood basin deposits. Table 3.2-9 summarizes construction undertaken to upgrade the levees in the mid-20th century, as shown in The Supplement to Standard Operation and Maintenance Manual for the Sacramento River Flood Control Project Unit No.116, from 1955.

The Yolo and Sacramento Bypass levees also have been upgraded since the 1950s, most recently in 1998 and 1999 by USACE when the levee crests were raised a maximum of 5 feet, damage from the 1997 flood repaired, and rock revetment added for wave and velocity erosion protection (Northwest Hydraulic Consultants Inc. 2007a). The revetment slumped in February 1998 and again at two sites near the Interstate 80 Bridge in January 2006. The revetment failures appear to result from slumping of saturated clays in the levee and foundation materials, resulting in failure of the revetment. Repairs of these failures are underway by DWR (Northwest Hydraulic Consultants Inc. 2007a). Levee soils are assumed to be similar to those along the DWSC West Levee (Kleinfelder 2007)[3].

[3] NHC had not received or reviewed a geotechnical data report for these levee sections since submittal of NHC 2007a.

Table 3.2-9. Historic Construction to Bring Levees Built by Local Interests to Project Standards

Job Order	Date	Location	Description

Source: Northwest Hydraulic Consultants 2007a.

Existing Bank Protection

There is no formal inventory of bank protection works along the Yolo and Sacramento Bypass levees; however, most of both levees are protected by revetment. As discussed above, revetment was placed on the upper end of the Yolo Bypass east levee and the south Sacramento Bypass levee in the late 1990s. Revetment covers about 540 feet around the pump station outlet in the Sacramento Bypass, consisting of quarry rock with a median size of about 9 inches and a maximum size of 12 inches. The portion of the Sacramento Bypass Levee directly below the Sacramento Weir is lined with concrete.

Casual inspection of the rock revetments along the Yolo Bypass Levee shows that they typically extend from the toe of the levee slope to the top of the levee crest upstream of Interstate 80 and from an elevation of about 27.57 feet (NAVD 88) to the levee crest downstream of Interstate 80 and appear to be designed to resist wind wave erosion. The revetment is constructed of quarry rock with a median size of about 12 inches and a maximum size of 20 inches. There was no evidence of damage from wave erosion along the sections inspected for this study.

Very little protection appears to have been placed along the DWSC West Levee. Kleinfelder (2007) noted revetment along the DWSC side of the levee along the southern part of Reach 9C to prevent boat wave erosion. Field inspection indicated erosion protection along the Yolo Bypass side of this levee, near where it joins the Yolo Bypass Levee.

Structures

Two outfalls from pump stations are located along the Sacramento and Yolo Bypass Levees. The Sacramento Bypass outfall is located at Station 1+50; the Yolo Bypass outfall at Station 79+50. Both outfalls are protected with rock riprap, and erosion was not observed near either outfall location.

Port of Sacramento and Deep Water Ship Channel East Levees (South Cross Levee, Deep Water Ship Channel East Levee, Port North Levee, and Port South Levee—Reaches 3, 4, 9A, and 9B)

Levee and Bank Geometry

DWSC East Levee (Reach 4)

The original Yolo Bypass Levees were incorporated into the DWSC construction, and the Yolo Bypass Levee was relocated to the west in 1960. The DWSC is located between the original levee (to

the east) and the new levee (to the west). Figure 5-2 of NHC 2007a shows a typical cross section of the DWSC East Levee. The levee crown is about 30 feet wide. Levee soils are typically low to high plasticity clays (Kleinfelder 2007). Along the upper levee the foundation materials consist of a blanket of clay that is 10 to 20 feet thick that is underlain by silt and silty sand. A sand layer extends 20 to 40 feet below the blanket of silt and silty sand. Along the lower part of the levee, the sand layer is 5 to 10 feet thick and underlain by highly plastic clay to maximum depths.

Port North and South Levees (Reaches 9A and 9B)

The Port North and South Levees were built in the early 1960s as part of the harbor development from material excavated during construction of the DWSC. The North Levee crest varies between 20.57 and 41.57 feet (NAVD 88) and is not well defined where it crosses high ground. Both the North and South Levees are set about 50 to 150 feet back from the shoreline around the harbor. Figure 5-3 of NHC 2007a provides a typical section through the Port North and South Levees. Levee soils and foundation materials vary considerably around the harbor. Kleinfelder (2007) provides details.

Structures

Kleinfelder (2007) notes two pumping stations along the DWSC East Levee. The Main Drain Pump Station (MDPS) is at about Station 101+00 (see their Plate 2C); another station is at 11+00. Erosion was noted near the outfall of each station (see Appendix A and C of NHC 2007a). Kleinfelder (2007) indicates that construction is underway to upgrade the MDPS and that plans at this site include either raising or flattening overly steep levee sections.

Bank Protection Works

There is no formal inventory of bank protection works placed along the DWSC and Port. Based on a review of available documents and field reconnaissance, there appear to be no designed bank protection works along the DWSC East Levee and the Port Levees. Small amounts of concrete rubble were observed during a brief field reconnaissance in the Port of Sacramento. Kleinfelder (2007) notes that revetment has been placed on the right bank of the DWSC near the southern part of the DWSC West Levee (Reach 9C).

Projected Incision Estimates and Erosion Mechanisms

The descriptions of projected incision and erosion mechanisms below are derived and summarized from NHC 2007a.

Projected Incision—Sacramento River Sites (Sacramento River North and South Levees—Reaches 1, 2, 7 and 8 of the West Sacramento Levee System)

NHC (2007a) examined the thalweg profiles for 1908, 1933, and 1997 for bed elevation trends by drawing smoothed upper and lower envelopes for each survey year, for the reach extending from Verona (RM 79) to Freeport (RM 46). Their analysis indicated the following:

- Over the greater part of the reach that extends downstream from RM 79 (Verona Gage) to RM 46 (Freeport Gage), thalweg levels dropped by an average of about 5 ft over the period 1908–33. This is equivalent to an average of about 0.2 ft/year.
- In the period 1933–1997, levels over the lower two-thirds of the same reach appear to have fallen on average by another 4 ft. This is equivalent to an average of about 0.06 ft/year.

When these assumed rates of incision are plotted as block averages against time and fitted by a smooth descending curve, they suggest a current incision rate of around 0.02 to 0.03 ft/year, probably declining to zero in less than 50 years. Even if the future rate is assumed to average 0.02 ft/year over a period of 50 years, the total future incision would amount to only 1 foot.

Information from various sources indicates that the low-water surface profile falls from about +8.57 ft NAVD 88 at Verona (RM 79) to +4.57 ft NAVD 88 at Freeport (RM 46). These elevations yield average low-water gradients at mean tide level of about 0.12 ft/mile (0.023 m/km) from Verona to Freeport, and 0.043 ft/mile (0.008 m/km) from Freeport to the Delta. These gradients are extremely flat in general terms, and further significant lowering of the quoted low-water levels is unlikely to occur.

In brief, given the apparent rates of incision in the second half of the 20th century and present low-water elevations, further significant incision of the Sacramento River downstream of Verona is unlikely to occur. Any further incision could hardly exceed 1 foot or so, an amount that is negligible compared to potential river-bed scour resulting from major floods.

Erosion Mechanisms

The erosion sites within the proposed program area are nearly all on unprotected banks or on banks where previous protection (often cobbles) has failed; nearly all the sites are along the Sacramento River South Levee (Appendix A of NHC 2007a). Inspections of the erosion sites indicated that the most common failure mechanisms along the right bank of the West Sacramento Reach of the Sacramento River were:

- Wave erosion, particularly from waves generated by recreational boat traffic on the Sacramento River. The erosion from boat traffic occurs during the summer and fall, when water levels are near their annual minima, and results in wave cut benches, steep eroding banks, and slow bank retreat. Erosion from wind-generated waves also occurs on the upper levee slopes during high flow events.
- Failures or slides on the berm, possibly as a result of over-steepening, saturation, toe scour, or other factors.
- Levee encroachment from scour at the toe of the bank where banks are steep below the water level and erosion has progressed into the 3:1 projected waterside slope of the levee template.
- Undermined or undercut trees that result in over-steepened and eroded section on the bank and that eventually will fall over, resulting in loss of bank or levee and further erosion as flows accelerate around the root ball.

These observations are consistent with previous reports on bank erosion along the Sacramento River (Northwest Hydraulic Consultants 2005, 2006; U.S. Army Corps of Engineers 2006).

As discussed earlier, much of the Sacramento River South Levee is protected by riprap revetment. These revetments are in reasonable repair and have withstood floods for 30 or 40 years and have been assumed to continue to provide erosion protection, given adequate maintenance. As such, they have a low risk of failure and a low priority for treatment. However, the rock placed on these slopes has been damaged by wave erosion, it is often smaller than currently recommended for protection from boat wakes and waves (U.S. Army Corps of Engineers 2006), and it is not known whether adequate toe rock was installed to protect against scour. Some upgrades or repairs may be required for certification, depending on standards adopted for these project levees by USACE.

3.2.2.2.5 Levee Deficiency Analysis

Section 4 of HDR, Inc. (2008a) includes the geotechnical assessment of the existing levees with regard to seepage, slope stability, and seismic vulnerabilities[4,5]. The information provided in HDR, Inc. (2008a) is derived from two reports: *West Sacramento Levee System Problem Identification and Alternative Analysis: Volume 1—Geotechnical Problem Identification Solano and Yolo Counties, California* (Kleinfelder 2007), and *Phase 1 Geotechnical Evaluation Report (P1GER) West Sacramento Region* (URS 2007).

Data collection included 323 borings drilled with standard penetration tests (SPTs) and soundings made using cone penetration test equipment (CPTs) along the levees within the basin. Approximate stationing endpoints have been determined by URS (2007) and Kleinfelder (2007) based on similar soil characteristics within the endpoints. Deficiencies identified within the approximate stationing endpoints do not indicate the entire stretch of levee contains said deficiency; rather a deficiency has been identified within the endpoints (HDR, Inc. 2008a).

Levee Seepage Analysis

Engineering analysis evaluating levee seepage along the northern reaches of the basin has been performed by URS (2007), and the findings were presented in their report titled *Phase 1 Geotechnical Evaluation Report (P1GER) West Sacramento Region* (URS 2007). URS (2007) performed their seepage analysis using water surface elevations that are different from the water surface elevations used in this chapter as determined by MBK Engineers (2007) and assumed a no-flow boundary at the center of the river (HDR, Inc. 2008a).

Table 3.2-10 shows the seepage summary of the northern reaches as completed by URS (2007). Exit gradients of 0.5 or greater for under-seepage require mitigation according to the USACE, and areas where through-seepage has been observed or projected based on soil conditions require mitigation.

Kleinfelder (2007) performed the engineering analysis evaluating levee seepage along the southern reaches of the basin and presented their findings in a report titled *West Sacramento Levee System Problem Identification and Alternative Analysis: Volume 1—Geotechnical Problem Identification Solano and Yolo Counties, California* (Kleinfelder 2007). Kleinfelder performed their analysis using the water surface elevations determined by MBK Engineers (2007) and assumed a total head boundary at the center of the river. The South Cross Levee had analysis completed only for the 100-year event because the difference in water surface elevation between the 100-year event and 200-year event is approximately 0.3 foot, and the probability of the South Cross Levee being affected during an event is dependent on failure of the Sacramento River South Levee (HDR, Inc. 2008a).

The seepage summaries for the southern reaches as completed by Kleinfelder (2007) are shown in Table 3.2-10. Exit gradients of 0.5 or greater for under-seepage require mitigation according to USACE, and areas where through-seepage has been observed or projected based on soil conditions require mitigation.

In brief, the Sacramento River North, the Sacramento River South, and the DWSC East Levees have a significant amount of under-seepage, whereas the other reaches have much less extensive under-seepage problems. Through-seepage is prevalent through the Sacramento River North, the

[4] Seismic vulnerabilities are discussed in Chapter 6, Geology, Seismicity, Soils, and Mineral Resources.

[5] HDR, Inc. (2008b) also discusses erosion and levee height deficiencies. Both are discussed below.

Sacramento River South, the Yolo Bypass, and the South Cross Levees. The other reaches have limited through-seepage problems (HDR, Inc. 2008b). See Table 3.2-11 and Figure 4 of HDR, Inc. (2008b) for additional information.

Levee Slope Stability Assessment

URS (2007) completed an engineering evaluation of levee slope stability and the effect of rapid drawdown for the northern reaches of the basin and presented their findings in the report titled *Phase 1 Geotechnical Evaluation Report (P1GER) West Sacramento Region* (URS 2007). As with the levee seepage analysis described above, URS (2007) used water surface elevations that are different

from the water surface elevations determined by MBK Engineers (2007) in their analysis of slope stability[6]. Rapid drawdown calculations have been completed only for the 100-year event as recommended to URS by their Independent Consulting Board (HDR, Inc. 2008a).

The slope stability results as completed by URS (2007) for the northern reaches are shown in Table 3.2-12.

Kleinfelder (2007) performed the engineering analysis evaluating levee slope stability and the effect of rapid drawdown along the southern reaches of the basin and presented their findings in a report titled *West Sacramento Levee System Problem Identification and Alternative Analysis: Volume 1—Geotechnical Problem Identification Solano and Yolo Counties, California* (Kleinfelder 2007). Kleinfelder (2007) performed their analysis using the water surface elevations determined by MBK Engineers (2007). The South Cross Levee had analysis completed only for the 100-year event because the difference in water surface elevation between the 100-year event and 200-year event is approximately 0.3 foot, and the probability of the South Cross Levee being affected during an event is dependent on failure of the Sacramento River West South Levee (HDR, Inc. 2008a).

The slope stability findings for the southern reaches as completed by Kleinfelder (2007) are shown in Table 3.2-12.

In brief, the Sacramento River North, the Sacramento River South, the Sacramento Bypass, and the Yolo Bypass levees have significant steady state stability deficiencies. The other reaches have less or none. Rapid drawdown stability appears to be a significant problem only along the Sacramento River South Levee (HDR, Inc. 2008b). See Table 3.2-11 and Figure 5 of HDR, Inc. (2008b) for additional information.

Levee Geometry Evaluation

To evaluate the crown width and side slopes of the levees in the proposed program area, HDR, Inc. (2008a) generated topography data by means of Light Detection and Ranging (LIDAR) using the North American Vertical Datum of 1988 (NAVD88).

USACE requires that levees have a maximum steepness of 3:1 (H:V) waterside slopes and 3:1 (H:V) landside slope. The design criterion for the WSLIP requires that the levees have 3:1 (H:V) for both waterside and landside slopes. Crown widths for primary levees are to be a minimum of 20 feet.

Refer to Appendix B in HDR, Inc. (2008a) for tables identifying sections of the levees that do not meet the design criterion. Appendix D in HDR, Inc. (2008a) contains LIDAR cross sections that have been used to evaluate levee geometry. Also refer to Figure 9 of HDR, Inc. (2008b), which shows the approximate locations where a geometry deficiency has been identified.

In brief, most of the levees in the proposed program area, with the exceptions of the Port South and DWSC East Levees, have a geometry deficiency, and typically it is an over-steepened waterside slope that is the primary problem (HDR, Inc. 2008b).

Erosion Evaluation

An inventory of current bank erosion sites has been performed to identify sections of the levee that might incur future stability or seepage problems because of bank erosion. The erosion sites have been identified by visual inspection of the entire proposed program area. Table 3.2-11 and Figure 7 of HDR, Inc. (2008b) summarize the results of the erosion evaluation. The sites have been prioritized based on significance of repairs needed to meet FEMA certification. The Sacramento River North Levee has three high priority sites totaling more than 1,100 feet. With the exception of one other long reach along the Yolo Bypass, there were no other high priority sites located in the northern West Sacramento basin (HDR, Inc. 2008b).

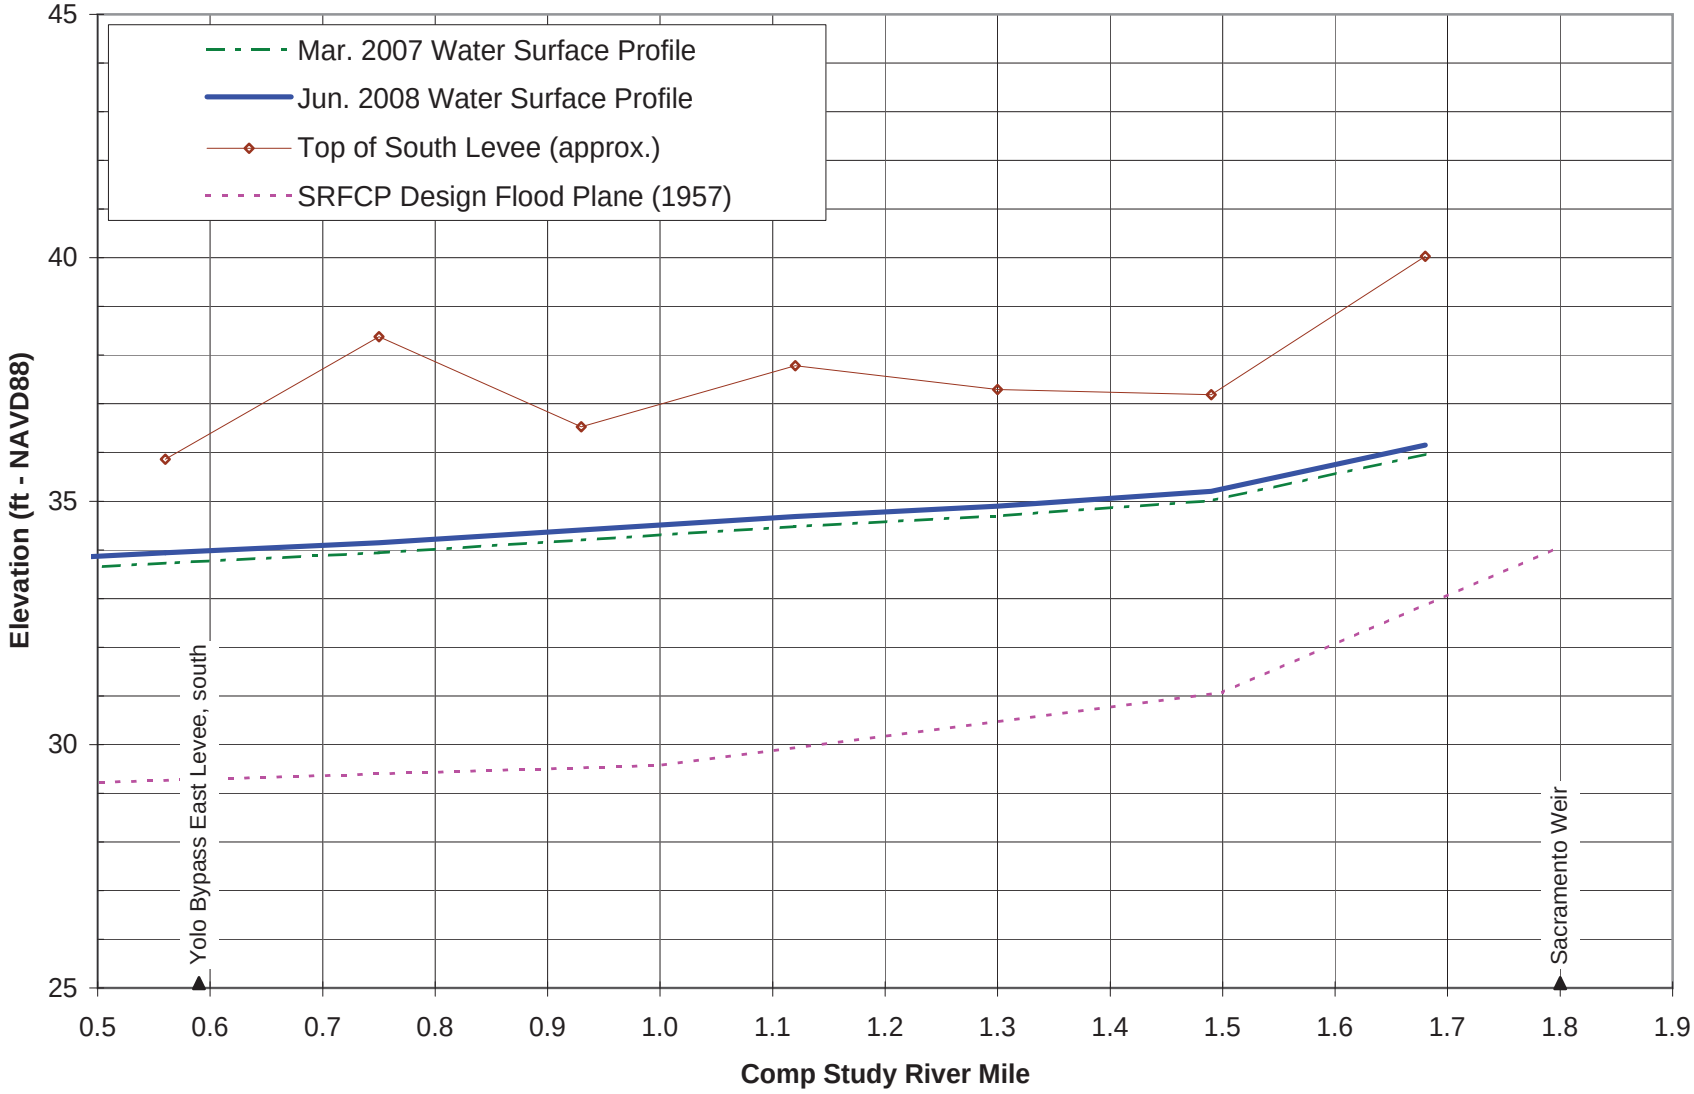
More than 4,000 feet of the Sacramento River South Levee were identified as having high priority erosion sites and another 1,000 feet were identified as having moderate priority erosion sites. The DWSC East Levee has two moderate priority erosion sites, both near the two pumping stations. The DWSC West Levee has the most significant degree of erosion with 60,000 feet of high priority erosion sites (HDR, Inc. 2008b).

For a complete summary of levee deficiencies, refer to Chapter 1, Introduction.

3.2.2.2.6 Flooding

Levees along the Sacramento River and other waterways provide flood control for the city of West Sacramento and conveyance for waters from upstream to the Delta. High winter flows can stress levees and berms. Longer flood durations can contribute to levee seepage and potentially structural levee failure. Flood water surface elevations also can exceed levee heights and cause overtopping and partially controlled flooding of the protected areas behind the levee. Overtopped levees may maintain structural integrity and would not be considered failed levees. However, the erosive forces that occur during overtopping eventually may cause a structural failure and uncontrolled flooding in the protected areas behind the levee. To maintain the integrity of the flood control system, locations with the potential for failure have been and are being identified and remedied.

MBK Engineers (2007, 2008a, and 2008b) has developed water surface profiles for use in this analysis. Their reports describe and present the results of a hydraulic analysis that was made to determine 1/100 and 1/200 AEP (commonly referred to as 100-year and 200-year) water surface elevations in the surrounding waterways, as well as the potential worst case flood depth for the South Cross Levee. The MBK version of the Comprehensive Study Sacramento River UNET model adopted for the Natomas Levee Improvement Program was used for this analysis. This adopted



version is capable of modeling anticipated levee breaks or of allowing levee overtopping without failures. UNET is a one-dimensional unsteady open-channel flow model with the ability to simulate exchange of flow over levees with storage areas. The MBK UNET model results were a maximum composite of simulations made using hydrologic data for two storm centering scenarios: Sacramento River at latitude of Sacramento and Feather River at Shanghai Bend. In addition, the American River peak flow in the 100-year flood was 145,000 cfs, the current FEMA condition and in the 200-year flood was 160,000 cfs, the expected future peak flow.

The resulting maximum water surface elevation profiles (for the 1/100 and 1/200 AEPs), the approximate tops of the levees, and the original 1957 Flood Control Project design floodplain for the Sacramento River, Sacramento Bypass, Yolo Bypass, and DWSC are provided in Figures 3.2-4 through 3.2-7 and Table 3.2-13.

The MBK UNET model indicates no levee overtopping will occur along the Sacramento River, Sacramento Bypass, Yolo Bypass, or the DWSC for the 100-year or the 200-year design floodflows. However, levee height criteria are not met for various reaches, specifically the Sacramento River North Levee, the Port North Levee, the Port South Levee, the DWSC West Levee, and the South Cross Levee. More information is provided in MBK Engineers' *Hydraulics Report for the City of West Sacramento Levee Alternatives Analysis* (2007) and Northwest Hydraulic Consultants' *West Sacramento Levees System: Problem Identification Report, Erosion Assessment and Treatment Alternatives, Draft for Review* (2007a).

Source: MBK Sacramento River UNET hydraulic model simulations documented in *Supplemental Report for the City of West Sacramento Levee Alternatives Hydraulic Analysis—Draft,* December 4, 2008.

[1] Assumes levees overtop without failing; existing conditions and operations.

[2] Assumes levees overtop without failing; urban levees have three feet of freeboard on 1/200 AEP water surface; non-urban levees satisfy SRFCP design freeboard requirements; Folsom Dam Joint Federal Project in place.

Flood Elevations and Levee Height Evaluation by Reach

As described in Section 4.3 of HDR, Inc. (2008a), the hydraulic models developed by MBK Engineers for 100-year and 200-year water surface flood conditions along the Sacramento River, DWSC, Sacramento Bypass, and Yolo Bypass have been used to assess levee conditions. Elevations have been presented in NAVD 88.

Freeboard is the additional levee height above the *adopted floodplain* (U.S. Army Corps of Engineers 1963), or as MBK Engineers 2008a, b) has phrased it, the *design water surface*. For the Sacramento River Flood Control Project, the adopted flood plane is the *project design floodplain* shown in the 1957 profiles.

Results from the hydraulic models have been used to assess levee height adequacy as compared to Federal and local agency criteria. All criteria must be considered, as policies are not consistent from agency to agency. As previously discussed in the Regulatory Setting section, the freeboard criteria as provided by the relevant agencies are summarized below.

- **FEMA**. Riverine levees must provide a minimum freeboard of 3 feet above the water-surface level of the base flood. An additional 1 foot above the minimum is required within 100 feet either side of structures (such as bridges) riverward of the levee or wherever the flow is constricted. An additional 0.5 foot above the minimum at the upstream end of the levee, tapering to not less than the minimum at the downstream end of the levee, is also required.

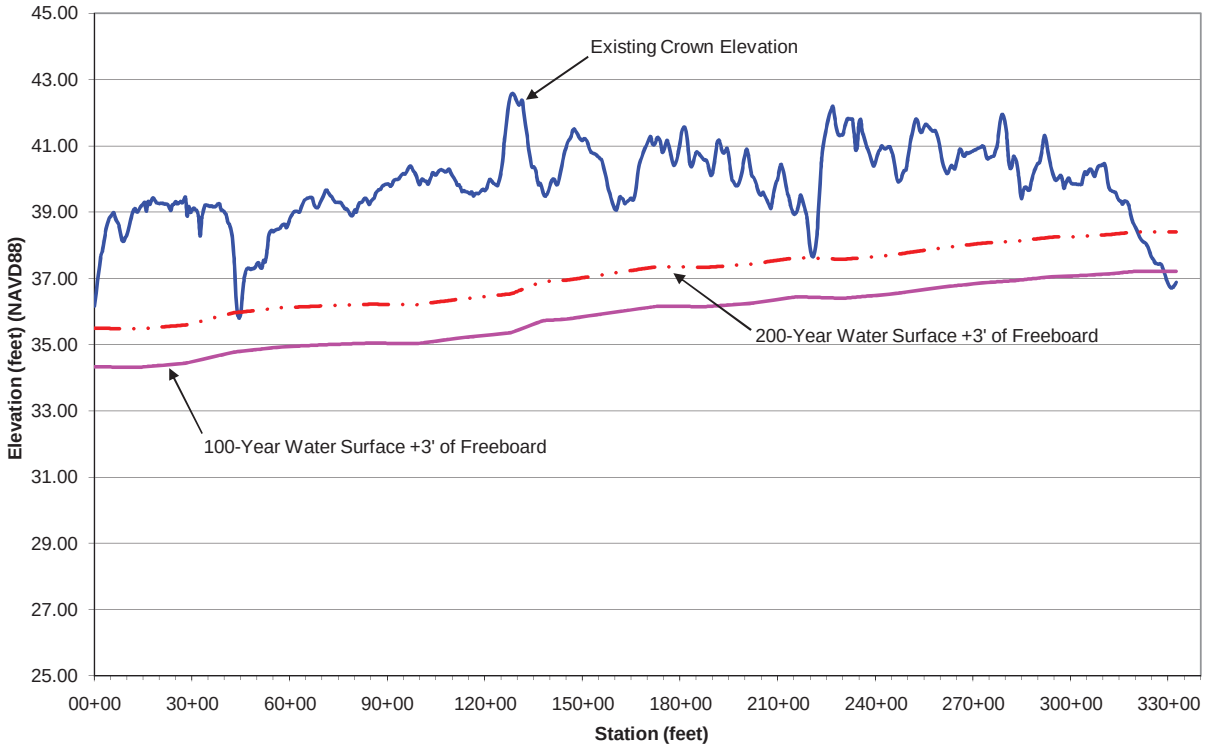
- **USACE.**
  - Sacramento River Levee: 3 feet
  - Sacramento Bypass Levee: 6 feet
  - Yolo Bypass Levee: 6 feet
  - DWSC Levees, Port North Levee, and Port South Levee: 3 feet for the Port (Turning Basin and Barge Channel) and 6 feet for the DWSC where it is adjacent to the Yolo Bypass
- **WSAFCA**. WSAFCA has no minimum freeboard requirements; rather, it uses the minimum freeboard requirements set forth by USACE.

Sacramento River South Levee

Figure 3.2-4 (MBK Engineers 2008a, b) shows the design water surface elevation profiles for the 1/100 and 1/200 AEPs, the approximate top of the west levee, and the original Federal Project Design Flood Plain from 1957 for the Sacramento River. As shown on the figure, water surface elevation for Sacramento River South Levee ranges between 30.99 and 35.42 feet in NAVD 88 for the 100-year flood, and between 32.16 and 36.61 NAVD 88feet for the 200-year flood on the Sacramento River.

Figure 3.2-8 (HDR, Inc. 2008a) shows the existing levee crown versus the computed flood water surface elevations. Throughout this reach, 3 feet of freeboard is maintained for both the 100-year and 200-year design floods (HDR, Inc. 2008a).

South Cross Levee

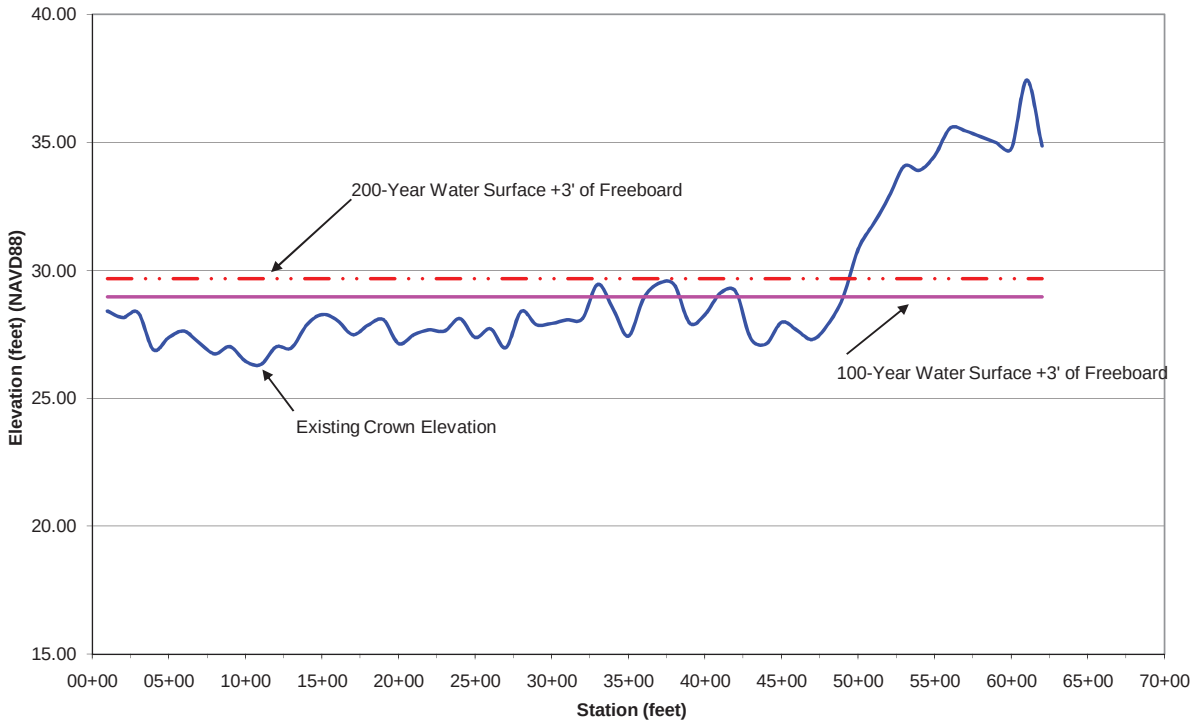


For the South Cross Levee, MBK Engineers developed 100-year and 200-year water surfaces considering a breach along the right bank of the Sacramento River (west levee) just downstream of the South Cross Levee. Figure 11 of MBK Engineers (2007) illustrates that the water surface elevation for South Cross Levee is 26.27 feet (NAVD 88) for the 100-year event and 26.67 feet for the 200-year event. MBK Engineers (2007) described in detail how the water surface elevations at the secondary levee at South Cross Levee have been developed (see Figures 7-11 of MBK Engineers [2007]).

More recently, MBK's 2007 analysis was updated with the current (MBK Engineers 2008a, b) hydraulic model and the results are presented and compared with those from the 2007 report in Table 10 and Figures 35 and 36 of MBK Engineers 2008a, b. The peak stage in feet (NAVD 88) for the 100-year event increased from 26.27 to 26.57 feet and the peak stage in feet (NAVD 88) for the 200-year event increased from 26.67 to 26.87 feet NAVD 88.

Figure 3.2-9 (HDR, Inc. 2008a) shows the existing crown versus the requirements of 3 feet of freeboard above the 100-year and 200-year water surfaces. As shown in the figure, there is inadequate levee height on the South Cross Levee to provide at least 3 feet of freeboard over both the 100-year and 200-year water surfaces (HDR, Inc. 2008a).

Port South Levee



The water surface elevation for Port South Levee remains constant at 18.8 feet (NAVD 88) for the 100-year event and 17.49 feet for the 200-year event on the Sacramento River (MBK Engineers 2007 as cited in HDR, Inc. 2008a).

Figure 3.2-9
Freeboard Evaluation of South Cross Levee

00875.07 EIS/EIR (03-10) AB

Figure 3.2-10 (HDR, Inc. 2008a) shows the existing crown versus the requirements of 3 feet of freeboard above the 100-year and 200-year water surfaces. As shown on the graph, there is inadequate levee height on the Port South Levee to provide at least 3 feet of freeboard over both the 100-year and 200-year water surfaces (HDR, Inc. 2008a).

DWSC East and West Levees

Figure 3.2-4 (MBK Engineers 2008a, b) shows the design water surface elevation profiles for the 1/100 and 1/200 AEPs, the approximate top of the east levee, and the original Federal Project Design Flood Plain from 1957 for the DWSC. As shown on the figure, the water surface elevation for the DWSC Levee is mostly 19.05 feet (between Comp Study River Miles 38.26 and 41.65) (NAVD 88) for the 100-year flood and between 20.21 and 20.23 feet (between Comp Study River Miles 38.26 and 41.65) for the 200-year flood on the Sacramento River.

Figure 3.2-11 (HDR, Inc. 2008a) shows the existing crown versus the requirements of 3 feet of freeboard above the 100-year and 200-year water surfaces. As shown on the figure, there is adequate levee height on the DWSC East to provide at least 3 feet of freeboard over both the 100-year and 200-year water surfaces (HDR, Inc. 2008a).

Figure 3.2-12 (HDR, Inc. 2008a) shows the existing crown versus the requirements of 3 feet of freeboard above the 100-year and 200-year water surfaces[7]. As shown on the figure, there is inadequate levee height on the DWSC West Levee based on the Yolo Bypass water data to provide at least 3 feet of freeboard over both the 100-year and 200-year water surfaces (HDR, Inc. 2008a).

Sacramento River North Levee

Figure 3.2-4 (MBK Engineers 2008a, b) shows the design water surface elevation profiles for the 1/100 and 1/200 AEPs, the approximate top of the west levee, and the original Federal Project Design Flood Plain from 1957 for the Sacramento River. As shown on the figure, water surface elevation for Sacramento River South Levee ranges between 30.99and 35.42 feet in NAVD 88 for the 100-year flood, and between 32.16 and 36.61 feet for the 200-year flood on the Sacramento River.

Figure 3.2-13 (HDR, Inc. 2008a) shows the existing crown versus the requirements of 5.57 NAVD 88 feet of freeboard above the 100-year and 200-year water surfaces. As shown on the graph, there is inadequate levee height on the Sacramento River North Levee to provide at least 5.57 NAVD 88 feet of freeboard over both the 100-year and 200-year water surfaces (HDR, Inc. 2008a).

Sacramento Bypass Levee

Figure 3.2-5 (MBK Engineers 2008a, b) shows the design water surface elevation profiles for the 1/100 and 1/200 AEPs, the approximate top of the South Levee, and the original Federal Project Design Flood Plain from 1957 for the Sacramento Bypass Levee. As shown on the figure, the water surface elevation for the Sacramento Bypass Levee ranges between 33.13 and 34.94 feet (NAVD 88) for the 100-year flood and between 33.94 and 36.15feet for the 200-year flood on the Sacramento River.

[7] Note that FEMA has a 3 foot freeboard requirement, but USACE has a 6 foot requirement for the DWSC where it is adjacent to the Yolo Bypass.

Figure 3.2-14 (HDR, Inc. 2008a) shows the existing crown versus the requirements of 5.57 (NAVD 88) feet of freeboard above the 100-year and 200-year water surfaces[8]. As shown on the graph, there is adequate levee height on the Sacramento Bypass Levee to provide at least 5.57 (NAVD 88) feet of freeboard over both the 100-year and 200-year water surfaces (HDR, Inc. 2008a).

Yolo Bypass Levee

Figure 3.2-6 (MBK Engineers 2008a, b) shows the design water surface elevation profiles for the 1/100 and 1/200 AEPs, the approximate top of the East Levee, and the original Federal Project Design Flood Plain from 1957 for the Yolo Bypass Levee. As shown on the figure, the water surface elevation for Yolo Bypass Levee ranges between below 23.38 (at Comp Study River Mile 28.87) and 32.23 feet (NAVD 88) for the 100-year event, and between below 24.72 (at Comp Study River Mile 28.87) and 33.36 feet for the 200-year event.

Figure 3.2-15 (HDR, Inc. 2008a) shows the existing crown versus the requirements of 5.57 (NAVD 88) feet of freeboard above the 100-year and 200-year water surfaces[9]. As shown on the graph, there is adequate levee height on the Yolo Bypass Levee to provide at least 5.57 feet of freeboard over both the 100-year and 200-year water surfaces (HDR, Inc. 2008a).

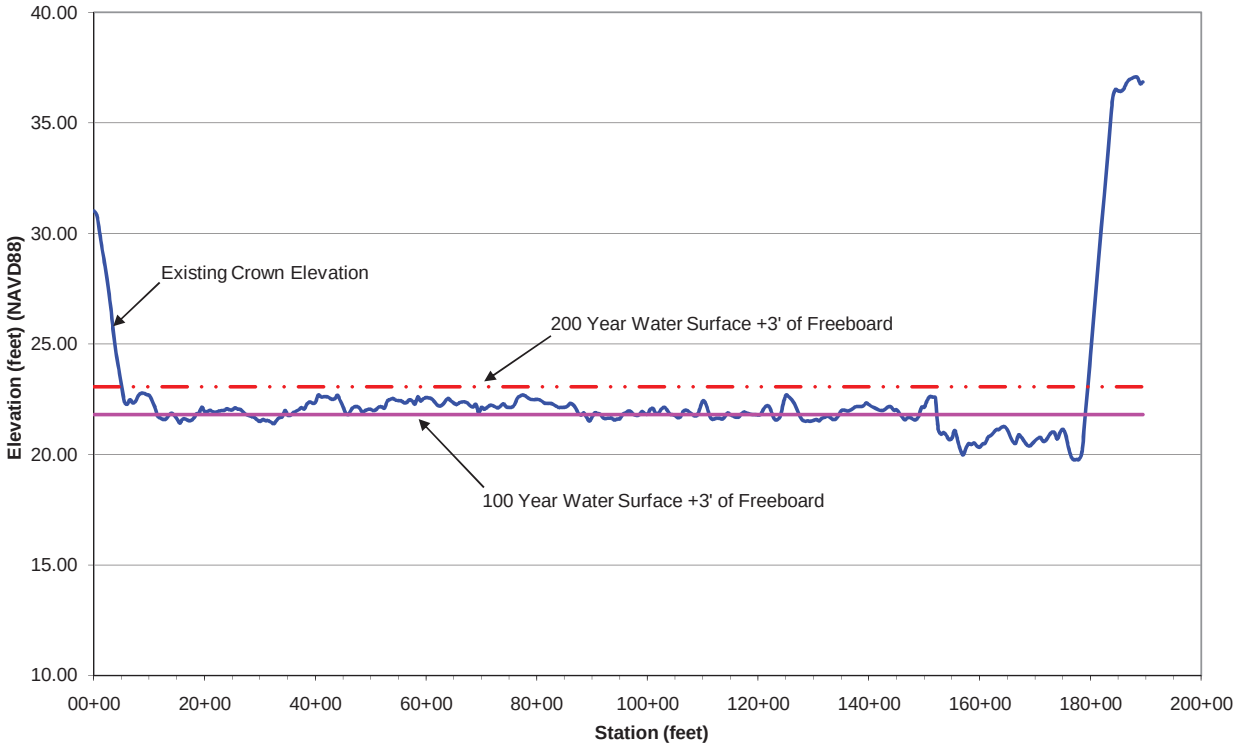
Port North Levee

The water surface elevation for Port North Levee is 18.72 feet (NAVD 88) for the 100-year flood and 20.06 feet for the 200-year flood event on the Sacramento River (MBK Engineers 2007 as cited in HDR, Inc. 2008a).

Figure 3.2-16 (HDR, Inc. 2008a) shows the existing crown versus the requirements of 5.57 feet of freeboard above the 100-year and 200-year water surfaces. As shown on the graph, there is inadequate levee height on the Port North Levee to provide at least 5.57 (NAVD 88) feet of freeboard over both the 100-year and 200-year water surfaces (HDR, Inc. 2008a).

Federal Emergency Management Agency Mapping Efforts

Based on the FEMA FIRMs, the locations of the designated floodplains in the study area are shown on Figures 3.2-17 and 3.2-18, and are summarized below.

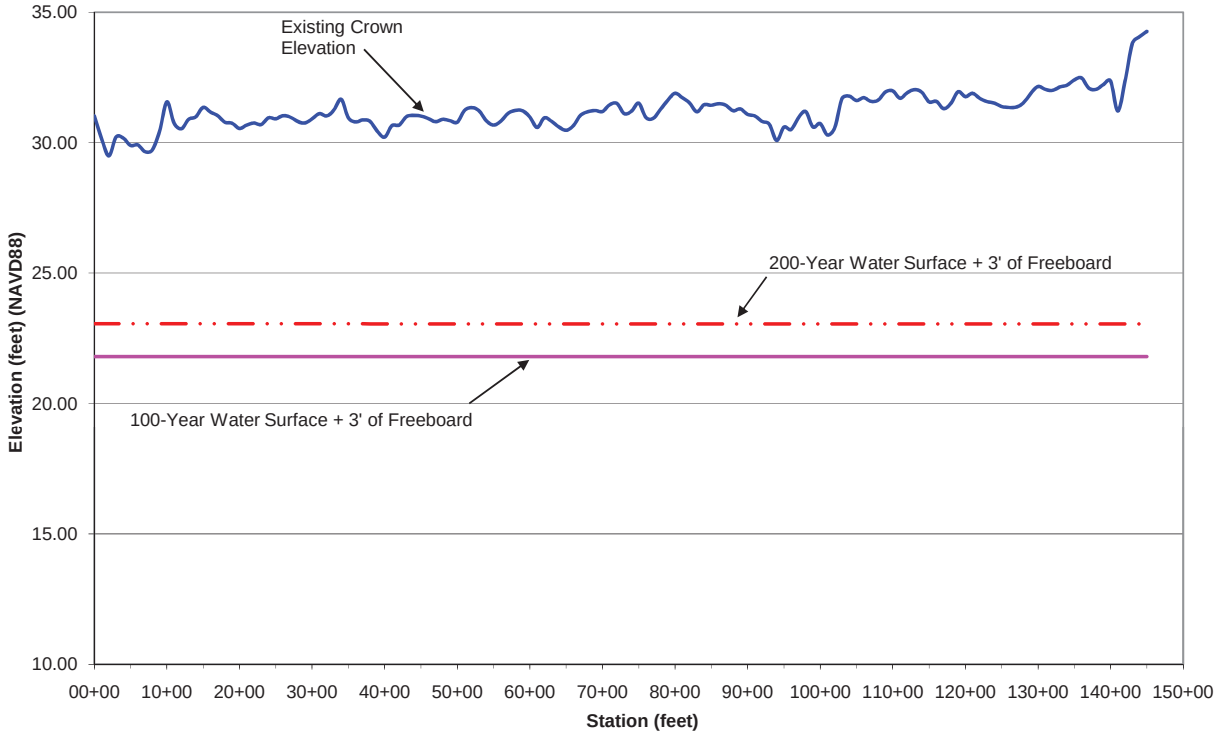


Federal Emergency Management Agency Parcel # 0607280005B City of West Sacramento, last updated 1995

The northern border of this area is the Sacramento Bypass and the southern border is near the Port of Sacramento. The eastern border is the toe drain on the west side of the DWSC, and the western border is the Sacramento River (Figure 3.2-17).

This residential-industrial area in the middle of the map is zoned by FEMA as being protected from the 1% chance of a 100-year flood by levee, dike, or other structures subject to possible failure of overlapping during longer floods. The Sacramento River, the toe drain, and the area northwest of the

[8] Note that FEMA has a 3-foot freeboard requirement, but USACE has a 6-foot requirement for the Sacramento Bypass Levee.



[9] Note that FEMA has a 3-foot freeboard requirement, but USACE has a 6-foot requirement for the Yolo Bypass Levee.

Interstate 80 / US Highway 50 area on the western end of the FEMA Map are designated as Zone AE. The water areas of the Port of Sacramento and Lake Washington are defined as Zone A.

Federal Emergency Management Agency Parcel # 0607280010B City of West Sacramento, last updated 1995

The northern border of the parcel map is the DWSC near the Port of Sacramento, the southern border is Riverview, the eastern border is the Sacramento River, and the western border is the toe drain on west side of the DWSC (Figure 3.2-18).

The residential area between the DWSC on the west and the Sacramento River to the east are considered by FEMA to be protected from the 1% chance (100-year) flood by levee, dike, or other structures subject to possible failure of overlapping during longer floods.

The Sacramento River on the eastern portion of the map is zoned as AE or Base Flood Elevations have been determined. The toe drain on the west end of the map is also zoned as AE. The DWSC, Lake Washington, and the other unknown pond in the northern portion of the FEMA Map are in Zone A.

3.2.2.2.7 Past Sea-Level Rise in the Program Area

MBK Engineers (2009b) applied the USACE sea-level rise guidance (U.S. Army Corps of Engineers 2009b) to the WSLIP in order to determine the effects of potential sea-level rise on the program area. Since the WSLIP sea-level rise analysis is in support of the pre-existing project design, many of the points in the USACE policy guidance do not apply, particularly those which refer to the comparison of project alternatives. The MBK Engineers (2009b) report uses the procedure for calculating sea-level rise which is identified in the USACE guidance and applies that procedure to the proposed WSLIP design.

Analysis of Historic Mean Sea Level Change

As described in the MBK Engineers report (2009b), the nearest tide station with sufficient period of record (40+ years recommended) is the National Oceanic and Atmospheric Administration (NOAA) station 9414290 at San Francisco, CA. Tidal records for this station have been maintained back to the 1850s.

The NOAA Center for Operational Oceanographic Products and Services (CO-OPS) has analyzed the historic mean sea level for this site has been shown to be increasing at a rate of 2.01mm/yr (California Climate Change Center 2009 as cited in MBK Engineers 2009b). Projections of future mean sea level change are discussed below.

3.2.2.2.8 Modeling of Hydraulic Effects

Three separate modeling efforts have been conducted for the WSLIP.

- In 2009, a modeling effort for the entire proposed program area was conducted by MBK Engineers (MBK Engineers 2009a).
- In 2007, MBK Engineers evaluated a levee setback on the Sacramento River just north of the Pocket area (Tustison pers. comm.).

- In 2009, MBK Engineers evaluated the potential effects of mean sea level change for the program area (MBK Engineers 2009b).

One previous modeling effort has also been used in the analysis of recreational elements for the WSLIP.

- In 2005, MBK Engineers performed a hydraulic analysis of the effects of potential cumulative development in the Sacramento River corridor floodway between Verona and Courtland on flood stages and flows (MBK Engineers 2005). The results are provided herein.

Evaluation of the Effects of the WSLIP

MBK Engineers (2009a) performed a hydraulic effect analysis for the City of West Sacramento to analyze the effects of the WSLIP on flood risk within the study area, both upstream and downstream of the study area.

Overall Modeling Approach

The MBK version of the Sacramento and San Joaquin River Basins Comprehensive Study (Comp Study) Sacramento River UNET model was used to calculate flood profiles and analyze effects. UNET is a one-dimensional unsteady open-channel flow model that was developed, and is supported, by the USACE Hydrologic Engineering Center. The upstream and downstream boundaries of the Comp Study UNET model are shown in Table 3.2-14 below.

Table 3.2-14. Sacramento River UNET Model Boundaries

Boundary Type	River	Location	USGS River Mile	Comp Study River Mile
Upstream	Sacramento River	Hamilton City	219.1	215.5
	Feather River	Thermalito Afterbay Outlet	59.0	58.6
	Yuba River	Below Englebright Dam	–	22.0
	Bear River	Wheatland Gage	–	12.5
	American River	Fair Oaks Gage	–	22.0
Downstream	Sacramento River	At Threemile Slough	9.4	9.5
	Georgiana Slough	At Mokelumne River	–	–

USGS = U.S. Geological Survey.

Model Assumptions

Table 3.2-15 defines the conditions analyzed and the various modeling assumptions that went with those conditions. As the table shows, an Existing, Without Project (analyzed as the No Action Alternative in the Environmental Consequences section), and a With Project condition were analyzed (analyzed as Flood Control and Recreation Program Alternatives in the Environmental Consequence section below.)

Table 3.2-15. Definition of Model Assumptions for Various Conditions

Condition	Top of Levee Assumption	Levee Failure Assumption	Reservoir Operation Assumption	Additional
Existing	Existing top of levee grade April 2008	No levee failure	Existing reservoirs and current (2008) operation criteria	
Without Project	Same as Existing with the following changes. Federally authorized improvements to Folsom Dam are implemented and urban area levees outside the West Sacramento Basin are assumed to have levees at 1-in-200-year water surface + 3 feet of freeboard. WSLIP levees same as Existing Condition.	No levee failure	Same as Existing except Folsom Dam will be operated in accordance with the Joint Federal Project currently under construction	
With Project	Same as Without Project except WSLIP levees raised to design level (1-in-200-year water surface + 3 feet of freeboard)	No levee failure	Same as Without Project	In-channel erosion protection

Source: MBK Engineers 2009a.

In addition to the project design elements, the water surface profiles developed for this analysis (without project and with project conditions) are based on the following criteria.

- The following components of the Three Rivers Levee Improvement Project are in place:
  - RD 784 Bear River levee setback,
  - RD 784 Western Pacific Interceptor Canal levee raise, and
  - RD 784 Feather River levee setback;
- Levee District 1 Feather River (west) levee setback is in place;
- Natomas Levee Improvement Project is in place; and
- Flood Control Project levees with deficient design freeboard were raised to eliminate the deficiency.

Hydrologic Inputs

USACE, as part of the Comp Study, developed input flows for the Comprehensive Study Sacramento River UNET hydraulic simulation model for the following hypothetical storm centerings (* indicates used in this analysis):

- Sacramento River Mainstem at Latitude of Ord Ferry
- Sacramento River Mainstem at Latitude of Sacramento*
- Stony Creek
- Shasta to Ord Ferry
- Butte Creek
- Feather River at Oroville
- Feather River at Shanghai Bend*

- Yuba River
- Bear River
- American River*
- Cache and Putah Creeks

Modeling Results

Tables 3.2-16, 3.2-17, and 3.2-18 summarize the maximum (or design) water surface elevations at several locations in and around the program area for the Existing, Without Project, and With Project conditions for the 1-in-100-year, 1-in-200-year and 1-in-500-year flood events, respectively.

There are no calculated effects of the WSLIP for the 1-in-100-year and 1-in-200-year flood events. For the 1-in-500-year flood, the maximum water surface elevation change on the Sacramento River between the Without Project and With Project conditions is 2.67 foot (NAVD 88) at RM 59.0 (2.66 is maximum difference for the selected locations in Table 3.2-18). However, even these relatively minor computed effects are considered extremely implausible, given the significant portion of upstream and adjacent levees overtopped (see Table 3.2-19 for quantification of the levee overtopping from this analysis and Appendix A in MBK Engineers [2009a] for analysis where upstream levees are allowed to fail) by this flood without any levee failures occurring.

[1] Lengths represent both right and left banks combined.

[2] Results displayed are for the Sacramento River storm centering.

Computed water surface elevation profiles for each key flow condition in the project area are shown in Figures 3.2-19 through 3.2-30[10].

[10] Figures 3.2-19 through 3.2-22 show the water surface elevation profiles of the 1-in-100-year flood; Figures 3.2-23 through 3.2-26 show the water surface elevation profiles of the 1-in-200-year flood; Figures 3.2-27 through 3.2-30 show the profiles for the 1-in-500-year flood.

Evaluation of the Effects of Sacramento River West Levee Setback at Oak Hall Bend

A proposed levee setback on the Sacramento River South Levee just north of the Pocket Area was evaluated by MBK Engineers (Tustison pers. comm.). This treatment has the most significant implications for hydraulic effects on the Sacramento River South Levee. This setback was aligned such that it cut off an oxbow feature in the Sacramento River, creating a more direct and wider route for water to flow downstream. Figure 1 of Tustison pers. comm. shows a map of the location of this levee setback on the Sacramento River South Levee.

Overall Modeling Approach

The MBK version of the Comprehensive Study Sacramento River UNET model adopted for the Lower Sacramento River Regional Plan was used to calculate flood profiles. UNET is a one-dimensional unsteady open-channel flow model that was developed, and is supported, by the USACE Hydrologic Engineering Center. The downstream boundary of the Comp Study UNET model is the Sacramento River at Collinsville, and the upstream boundaries on the major rivers are listed below.

- Sacramento River Woodson Bridge (RM 215.5)
- Feather River Thermalito Afterbay Outlet (RM 58.6)
- Yuba River Englebright Reservoir (RM 22.0)
- Bear River Wheatland Gage (RM 12.5)
- American River Fair Oaks Gage (RM 22.0)

The topographic information in the model was developed by USACE in 1998.

Model Assumptions

The following primary assumptions were used in the analysis:

- existing physical conditions,
- levees throughout the Sacramento River system overtop without failure, and
- Federal levees deficient of 1957 design were raised to comply with 1957 design top of levee.

Setback Information

The levee setback was modeled by moving the existing Sacramento River West Levee laterally by the appropriate setback distance as calculated via the setback levee alignment (See Figure 1 of Tustison pers. comm.) from HDR, Inc. The setback affects seven model cross sections between Comprehensive Study RMs 54.75 and 53.25 (USGS RMs 54.4 and 52.9). Figures 2a–2g of Tustison pers. comm., included in the appendix, show these cross sections under existing conditions and with the proposed setback levee. It is unknown what the eventual land use of the setback area will be; therefore, MBK Engineers used a relatively high roughness value of n=0.10 in the setback area (a value of n=0.03 was used in the without project condition for the right overbank in this reach).

Modeling Results

The hydraulic analysis was performed with the Comp Study Sacramento River at Sacramento hydrologic centering, the predominant centering for this reach, for the 1-in-100 AEP and 1-in-200 AEP flood events. The American River at Folsom Dam outflow was modified so that the peak flow

was 145,000 cfs in the 1-in-100 AEP event and 160,000 cfs in the 1-in-200 AEP event. The hydrographs were obtained from the most recent (August 2006) Folsom Dam operational data from USACE.

The peak water surface elevation profiles with and without the levee setback are presented in Figure 3 of Tustison pers. comm. Tables 3.2-20a and 3.2-20b show the maximum modeled flow rates at several key locations for the 1-in-100 AEP and 1-in-200 AEP flood events, respectively. Tables 3.2-21a and 3.2-21b give the maximum water surface elevation values at the same key locations.

As the figure and tables show, the setback levee generally decreases the water surface upstream of the setback, while areas downstream see slightly higher water surfaces (as well as an increase in flow). The slight decrease in the water surface elevation at and upstream of the setback levee (associated with the increased floodplain capacity) results in a slight increase in the flow in the Sacramento River downstream of the American River with a corresponding decrease in the flow across the Sacramento Weir. The increased stage downstream of the setback is the result of this flow increase (Tustison pers. comm.).

Projections of Future Mean Sea Level Change

As discussed above, MBK Engineers (2009b) applied the USACE sea-level rise guidance (U.S. Army Corps of Engineers 2009b) to the WSLIP in order to determine the effects of potential sea-level rise on the program area.

As specified in the USACE policy, three future mean sea level trends were calculated for the program area. These are:

- Low—using historic trend of mean sea level change;
- Intermediate—considering most recent IPCC and NRC Curve I projections of mean sea level change;
- High—considering NRC Curve III projections of mean sea level change.

Table 3.2-22 shows the results of applying the rates and relationships for 25, 50, and 100 years after the project is constructed. For the calculations, a project construction year of 2012 was assumed (MBK Engineers 2009b).

Table 3.2-22. Calculated Sea-Level Rise for 25, 50, and 100 Years after Project Construction using Intermediate and High Rates of Sea-Level Rise

Years after Project Constructed	Calculated Sea-Level Rise (feet)		
	Low Rate	Intermediate Rate	High Rate
25	0.16	0.30	0.79
50	0.33	0.69	1.97
100	0.66	1.74	5.58

Source: MBK Engineers 2009b.

Hydraulic model simulations were developed to evaluate hydraulic impacts on the WSLIP design of low, intermediate, and high rates of sea-level change 25, 50 and 100 years, respectively, from the project construction date. The Sacramento River UNET Hydraulic Model was used for this purpose, as well as to analyze the WSLIP design, as described above. The same model parameters were used for both analyses.

The results of the hydraulic simulations are shown in Table 3.2-23. This table lists the changes in the maximum (peak) water surface elevations for the WSLIP design simulations under the specified sea-level rise scenarios at various points through the flood system. The sea-level rise scenario results are compared with the WSLIP design (no sea-level rise).

1

As Table 3.2-23 illustrates, the WSLIP program area is relatively insensitive to the rates of sea-level rise. Of all the scenarios analyzed, only the high sea-level rise rate 100 years after the project is constructed shows greater than one-tenth of a foot stage increase in the Sacramento River, Yolo Bypass, or Sacramento Bypass in the WSLIP program area.

The Port of Sacramento and the DWSC see larger increases resulting from sea-level rise. The DWSC is primarily backwater controlled and is hydraulically connected to the rest of the flood system fairly close to the sea (i.e., North Delta). The WSLIP design for the DWSC indicates there is adequate freeboard available to accommodate a water surface increase of the magnitudes reported herein due to sea-level rise and still maintain the minimum project design freeboard of three feet (MBK Engineers 2009b).

Evaluation of the Effects of Potential Cumulative Development in the Sacramento River Corridor Floodway

MBK Engineers (2005) performed a hydraulic analysis of the effects of potential cumulative development in the Sacramento River corridor floodway between Verona and Courtland on flood stages and flows.

Overall Modeling Approach

The effect analysis was done using a modified version of the Sacramento River basin UNET model developed by USACE for the Comp Study. The model was modified and recalibrated as documented in *Modifications, Refinements and Re-Calibration of the Sacramento and San Joaquin River Basins Comprehensive Study Sacramento Basin UNET Model* (MBK Engineers 2003).

The Sacramento River basin UNET model, which was calibrated to the January 1997 flood event, includes the following river reaches, along with numerous tributaries to these rivers:

- Sacramento River from Woodson Bridge (River Mile 218) to Collinsville (RM 0)
- Feather River below Thermalito (RM 58.5)
- Yuba River below Englebright Reservoir (RM 22)
- Bear River below Wheatland (RM 12.5)
- Sutter Bypass
- American River below Folsom Lake (RM 22.0)
- Yolo Bypass

Cumulative Development Components

The study area for the cumulative conditions hydraulic analysis was the Sacramento River from the Fremont Weir to just below Courtland as shown in Figure 1 of MBK Engineers (2005). The cumulative development components included in the analysis include the following elements:

- new bridges;
- addition of dense private docks, fishing piers, and waterside rock bench armoring;
- new marina complexes; and

- riparian vegetation enhancement.

Detailed descriptions of the components included in the hydraulic model and how they were modeled are provided in sections 3.1, 3.2, 3.3, and 3.4 of MBK Engineers (2005).

Hydrologic Inputs and Assumptions

As part of the Comp Study, USACE developed a hydrologic data set for the Sacramento River Basin UNET model. The hydrologic data set includes flow data for the UNET model upstream boundaries for flood events with 2-, 10-, 25-, 50-, 100-, 200- and 500-year return frequencies that were developed from the following 11 hypothetical storm centerings:

- Ord Ferry (Sacramento River mainstem at latitude of Ord Ferry)
- Sacramento (Sacramento River mainstem at latitude of Sacramento)
- Stony Creek
- Shasta
- Butte Creek
- Oroville
- Yuba River
- Bear River
- American River
- Cache and Putah Creeks
- Delta

The hydrology used for this analysis was the Sacramento centering, which was developed to place the most stress on the system at the latitude of Sacramento.

Effects of the cumulative development were determined for two flood events:

- January 1997 Flood.
- Maximum flow flood event. This event is modeled using the 1 in 100 AEP flood event on the Sacramento River basin with the 1 in 200 AEP flood event on the American River. The flow data used were from the Sacramento centering hydrology developed by the Corps for the Comp Study. The Maximum Flow flood event simulation used a system-wide assumption that levees would overtop but would not fail. This combination of events and levee assumptions represents a maximum flow condition for the urban center from the Sacramento Weir downstream to Freeport.

Hydraulic Analysis and Results

January 1997 Flood Simulation—Water Surface Elevation

Plots of the Sacramento River maximum water surface January 1997 flood simulation profiles for with and without cumulative development are provided in Figure 20 of MBK Engineers (2005). The effects of the cumulative development at various locations are highlighted on the profile plots.

Table 3.2-24 summarizes maximum water surface elevations and corresponding cumulative development effects.

The maximum water surface elevation increase attributable to the cumulative development is 0.20 foot just upstream of Interstate 5. The effect downstream of the American River through the downtown Sacramento area ranges from +0.05 to +0.07 foot. From the Pocket area downstream, the cumulative development results in a maximum water surface elevation reduction. This reduction is the result of a flow reduction in the Sacramento River downstream of the American River as a result of slight increases in the diversions at the Fremont and Sacramento Weirs. The flow and velocity effects are discussed in more detail in sections 5.2 and 5.3, respectively, of MBK Engineers (2005). The amount of additional flow being diverted to the Yolo Bypass is small relative to total flow being diverted and results in a maximum effect on the Yolo Bypass water surface elevation of +0.03 foot.

Table 3.2-24. Peak Stages and Impacts

	January 1997 Flood Simulation			Maximum Flow Flood Simulation		
	Peak Stage (feet NAVD 88)		Impact	Peak Stage (feet NAVD 88)		Impact

Maximum Flow Flood Simulation—Water Surface Elevation

Plots of the Sacramento River maximum water surface maximum flow flood simulation profiles for with and without cumulative development are provided in Figure 21 of MBK Engineers (2005). The effects of the cumulative development at various locations are highlighted on the profile plots. Table 3.2-24 summarizes maximum water surface elevations and corresponding cumulative development effects.

The maximum water surface elevation increase attributable to the cumulative development is 0.15 foot just upstream of I-5. The effect downstream of the American River through the downtown Sacramento area ranges from +0.03 to +0.05 foot. From the Pocket area downstream, the cumulative development results in a maximum water surface elevation reduction. This reduction is the result of a flow reduction in the Sacramento River downstream of the American River as a result of slight increases in the diversions at the Fremont and Sacramento Weirs. The flow and velocity effects are discussed in more detail in Sections 5.2 and 5.3, respectively, of MBK Engineers (2005). The amount of additional flow being diverted to the Yolo Bypass is small relative to total flow being diverted and results in a maximum effect on the Yolo Bypass water surface elevation of +0.02 foot.

3.2.3 Environmental Consequences

This section describes the methods used to determine the effects of the program and lists the thresholds used to conclude whether an effect would be significant. Then it discusses each effect and the treatment(s) to which it applies and the reaches where the effect occurs, concludes whether the effect would be significant, and lists any measures to mitigate (i.e., avoid, minimize, rectify, reduce, eliminate, or compensate for) significant effects. How an effect differs among reaches is discussed, as applicable.

3.2.3.1 Methods

Assessment of environmental effects associated with hydrology, hydraulics, geomorphology, and flood control issues has been accomplished through the following means:

- MBK Engineers (2009a) quantitative modeling of the WSLIP,
- MBK Engineers (2009b) report on effects of projected sea level change,
- MBK Engineers (2007) quantitative modeling of the effects of Sacramento River West Levee Setback at Oak Hall Bend,
- MBK Engineers (2005) hydraulic analysis of the effects of potential cumulative development in the Sacramento River corridor floodway between Verona and Courtland on flood stages and flows,
- an evaluation of existing conditions of proposed program area levees and projected incision and scour estimates in the adjacent waterways,
- qualitative assessments of sedimentation/scour potential based on existing Federal and state channel hydraulic design standards and guidelines, and
- determination of effects through professional judgment.

3.2.3.2 Determination of Effects

Here the thresholds for significance under CEQA are listed and, if there are NEPA thresholds, these are also identified. In this joint Federal and state EIS/EIR, reference to “significant impacts” is made to fulfill the requirement under CEQA, pursuant to standards of California law. If there are differences between the CEQA and NEPA thresholds, these are identified. However, regardless of level of significance, all potentially significant environmental effects have been analyzed and are discussed.

The criteria used for determining the significance of an effect on hydrology, hydraulics, geomorphology, and flood control are based on Appendix G of the State CEQA Guidelines (Environmental Checklist) and professional standards and practices.

Effects on hydrologic or geomorphic conditions may be considered significant if implementation of an alternative would:

- substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, in a manner that would result in substantial erosion or siltation on or off site;
- substantially alter the existing drainage pattern of the site or area, including the alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in a manner that would result in flooding on or off site;
- place within a 100-year flood hazard area structures that would impede or redirect floodflows; or
- expose people or structures to a significant risk of loss, injury, or death involving flooding, including flooding as a result of the failure of a levee or dam.

Effects on flood control may be considered significant if implementation of an alternative would:

- significantly raise flood stage elevations;
- increase the frequency and duration of inundation of lands; or
- expose people or structures to a significant risk of loss, injury, or death involving flooding, including flooding as a result of the failure of a levee.

An effect on the levee system is considered significant if an alternative would substantially increase any of the following:

- seepage,
- levee settlement,
- wind erosion,
- bank erosion or bed scour,
- sediment deposition, or
- subsidence of land adjacent to levees.

In addition, an effect on the levee system is considered significant if an alternative would substantially decrease any of the following:

- levee stability;
- inspection, maintenance, or repair capabilities;
- current level of levee slope protection;
- emergency response capabilities;
- channel conveyance capacity; or
- the ability of the levees to withstand seismic forces.

3.2.3.3 Effects and Mitigation Measures

This section analyzes program effects for the study area. Local, upstream, and downstream effects are analyzed separately where applicable, but are also described in more detail as part of the Cumulative Effects discussion in Chapter 6, Growth-Inducing and Cumulative Effects. Effects related to mean sea level change are only addressed in the No Action Alternative below because, as described above, the WSLIP program area is relatively insensitive to the rates of sea-level rise. Of all the scenarios analyzed, only the high sea-level rise rate 100 years after the project is constructed shows greater than one-tenth of a foot stage increase in the Sacramento River, Yolo Bypass, or Sacramento Bypass in the WSLIP program area.

3.2.3.3.1 No Action Alternative

Under the No Action Alternative, the geomorphic and flood control regimes would not change relative to existing conditions. However, the current levees would remain susceptible to failure as a result of existing levee deficiencies such as seepage, erosion, inadequate height, and slope instability. Under these conditions, any of the levee deficiencies could cause portions of the levee system to fail, triggering widespread flooding and extensive damage to the city's existing residential, commercial, agricultural, and industrial structures, and potential loss of life (refer to Figure 2-2: *100-Year Flood Event Estimated Flood Depths* for the 100-year programmatic flood scenario which indicates that inundation levels would range from 1 foot to 15 feet throughout the City, depending upon the elevation of the land surface; also refer to the discussion in Chapter 2 for additional information). If levees were breached or overtopped by the Sacramento River, DWSC, or Yolo or Sacramento bypasses, the West Sacramento basin(s) would fill with water and hydrostatic pressure on the both sides of the levees could cause excessive saturation and levee weakening. This condition would further reduce levee integrity and result in an even greater risk of levee collapse, failure and further flooding and damage.

Furthermore, there are several proposed levee strengthening projects in upstream areas (See Section 1.6, Related Actions, Programs, and Planning Efforts) that may transfer flood risk to the study area if the levees within the study area were to remain below current engineering standards while other upstream levees were improved to meet or exceed current standards. Given the uncertainty of the occurrence or magnitude of such an event, potential effects on geomorphic and flood control conditions cannot be quantified based on available information.

Additionally, with respect to future mean sea-level change, the Port of Sacramento and the DWSC see larger increases from sea-level rise than the other reaches. The WSLIP design for the DWSC indicates there is adequate freeboard available to accommodate a water surface increase of the magnitudes reported herein due to sea-level rise and still maintain the minimum project design freeboard of three feet (MBK Engineers 2009b); however, if the project were not to be constructed, then future mean sea level rise would certainly be a concern for this reach.

In its levee vegetation guidance, the USACE has established a woody vegetation free zone required for operations and maintenance of Federal project levees. Compliance with this levee vegetation guidance could result in the removal of a substantial amount of vegetation. However, compliance with future vegetation policy enforcement on the study area levees would not have any noteworthy effects on the geomorphic and/or flood control regimes of the Sacramento River within the study area.

3.2.3.3.2 Flood and Recreation Program Alternatives

Effect FC-1: Change in Water Surface Elevations and Flood Safety Attributable to Project Design

Local and Upstream Effects (Flood Program)

No significant local or upstream flood control–related effects are associated with a levee raise, a setback levee or installation of stop logs or a floodwall for the Sacramento River North, Sacramento River South, Port North, Port South, South Cross, DWSC East and West, and Yolo Bypass Levees, as those treatments would help minimize flooding locally behind the improved levees and enable the levees to meet associated regulatory criteria.

As determined through a robust modeling effort for the WSLIP, MBK Engineers (2009a) concluded that there are no calculated effects of the WSLIP for the 1-in-100-year and 1-in-200-year flood events (see Tables 3.2-16 and 3.2-17 above). For the 1-in-500-year flood, the maximum water surface elevation change on the Sacramento River between the Without Project and With Project conditions is 0.10 foot at RM 59.0 (see Table 3.2-18 above). However, even these relatively minor computed effects are considered extremely implausible, given the significant portion of upstream and adjacent levees overtopped (see Table 3.2-19 above for quantification of the levee overtopping from this analysis and Appendix A of MBK Engineers [2009a] for analysis where upstream levees are allowed to fail) by this flood without any levee failures occurring.

Based on the quantitative results from the MBK Engineers modeling effort (2009a), upstream water levels would not be significantly affected by the proposed levee raises or other treatments either, assuming that all upstream levee strengthening components described above in Table 3.2-15 are eventually implemented.

Raising levees or implementing the other treatments would not significantly alter water surface elevation in and above the proposed program area. These treatment would not significantly change the geometry of the Sacramento River and therefore would not cause significant changes to water flow in the river or cause negative hydraulic effects within or upstream of the proposed program area. Levee raises, setback levees, closure structures, and floodwalls would not expose people or structures to a significant risk of flooding. Rather, this risk would be alleviated because these treatments would reduce the risk of levee overtopping for the 100- and 200-year floods. Because these treatments would upgrade existing levees using up-to-date design and construction standards, their implementation would reduce the risk of flooding for the proposed program area.

Downstream Effects (Flood Program)

Levee raises or setbacks and installation of closure structures or floodwalls could represent an unacceptable transfer of flood risk to adjacent or downstream levee districts. However, as described in MBK Engineers (2009a) modeling effort for the WSLIP, raising and strengthening portions of the Federal project levee system protecting West Sacramento and implementing in-channel erosion protection measures would not result in any significant hydraulic effects on other sub-basins protected as part of the Flood Control Project. Furthermore, these improvements would be consistent with the principles that have guided the management of the Flood Control Project over the past century and with the policies adopted by the State Legislature calling for an immediate and comprehensive effort to increase the level of flood protection provided to West Sacramento and the other urban areas within the Flood Control Project.

Local and Upstream Effects (Recreation Program)

Modeling results for the January 1997 Flood Simulation performed by MBK Engineers (2005) concluded that water surface elevation effects downstream of the American River through the downtown Sacramento area range from +0.05 to +0.07 feet. Modeling results for the Maximum Flow Flood Simulation performed by MBK Engineers (2005) concluded that water surface elevation effects downstream of the American River through the downtown Sacramento area range from +0.03 to +0.05 feet.

Downstream Effects (Recreation Program)

Modeling results for both the January 1997 Flood Simulation and the Maximum Flow Flood Simulation performed by MBK Engineers (2005) concluded that from the Pocket area downstream impacts of the cumulative development result in a maximum water surface elevation reduction. This reduction is the result of a flow reduction in the Sacramento River downstream of the American River due to slight increases in the diversions at the Fremont and Sacramento Weirs. The flow and velocity impacts are discussed in more detail in Sections 5.2 and 5.3, respectively, of MBK Engineers (2005).

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full)	▪ Closure structure ▪ Setback levee ▪ Flood wall
Recreation	▪ Riverside parks	▪ Developed water access

Affected Reaches

Although different flood program alternatives are proposed for the reaches, this effect would occur in the following reaches: Sacramento River North, Sacramento River South, Port North, Port South, South Cross, DWSC East and West, and Yolo Bypass.

Effect FC-1 Finding	With Mitigation
Flood: Beneficial (local and upstream) Flood: Less than significant (downstream) Recreation: Less than significant (local, upstream and downstream)	

Effect FC-2: Decrease in Risk of Levee Failure as a Result of Erosion or Seepage

Flood program alternatives such as an adjacent, full, or in-place levee raise would add material to the levee, which would help to decrease relative erosion. More levee material would require a greater amount of erosion to cause a breach. Presently, in the Sacramento River North and South reaches, the average velocities during the 200-year projected peak flow do not present a significant concern for surface erosion by flows parallel to the bank, except where the banks have no vegetation

or other bank protection or where significant obstructions project into the flow and generate eddies and complex flows capable of eroding the streambank (Northwest Hydraulic Consultants 2007a).

A new setback levee alternative would involve up-to-date design and construction methods to avoid erosion, and it is assumed that bank erosion on the newly reshaped bank (i.e., former levee surface) on the waterside would remain minimal as features associated with this treatment would be engineered to withstand the forces of erosion by flowing water.

Additionally, levee raises and/or the construction of a setback levee would provide more material in the landward direction to help reduce the levee through-seepage potential. These treatments would not result in any long-term changes to the overall existing drainage pattern of the study area Furthermore, they would not change the existing potential for through-seepage upstream and downstream of the study area as water surface elevations would not change significantly upstream or downstream, and current seepage rates do not contribute to substantial reductions in channel flows or water surface elevations. The change in hydrologic conditions resulting from these treatments is not expected to result in a substantial increase in seepage through or under adjacent levees because any upstream or downstream levee will be engineered appropriately to an equal level of protection. Within the study area itself, other treatments aim to rectify through-seepage concerns.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Levee raise (adjacent)	▪ Levee raise (in place)
	▪ Levee raise (full)	▪ Setback levee

Affected Reaches

Although different flood program alternatives are proposed for the reaches, this effect would occur in the following reaches: Sacramento River North, Sacramento River South, Port South, South Cross, and DWSC East and West.

Effect FC-2 Finding	With Mitigation
Beneficial	N/A

Effect FC-3: Alteration of the Existing Drainage Pattern of the Site or Area

Implementation of flood program alternatives (adjacent levee raise, full levee raise, setback levee, slope flattening, relief wells, stability berm, interior drain, seepage berm), and recreation program alternatives could involve earthwork on the landward side of the levee. The new material on the landside could cross drainage infrastructure maintained by local landowners or local agencies in some locations or alter surface runoff patterns. Because interference with drainage could cause or exacerbate local flooding, this effect would be potentially significant. The presence of the newly modified levee itself could also alter the course of local runoff. The implementation of Mitigation Measure FC-FC-MM-1 would reduce this effect.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Setback levee ▪ Slope flattening	▪ Relief wells ▪ Stability berm ▪ Interior drain ▪ Seepage berm
Recreation	▪ Trails	▪ Special projects

Affected Reaches

Although different flood program alternatives are proposed for the reaches, this effect would occur in the following reaches: Sacramento River North, Sacramento River South, Port North, Port South, South Cross, DWSC East and West, Sacramento Bypass, and Yolo Bypass.

Effect FC-3 Finding	With Mitigation
Significant	Less than significant

Mitigation

Mitigation Measure FC-MM-1: Coordinate with Owners and Operators, Prepare Drainage Studies as Needed, and Remediate Effects through Project Design

The agencies implementing program components and their primary contractors for engineering design and construction will ensure that the following measures are implemented to avoid significant effects associated with disruption of local drainage systems.

During project design, project engineers will coordinate with owners and operators of local drainage systems and landowners served by the systems to evaluate pre- and post-WSLIP drainage needs and design features to remediate any program-related substantial drainage disruption or alteration in runoff that would increase the potential for local flooding. If substantial alteration of runoff patterns or disruption of a local drainage system could result from a project feature, a drainage study will be prepared as part of project design. The study will consider the design flows of any existing facilities that would be crossed by project features and develop appropriate plans for relocation or other modification of these facilities and construction of new facilities, as needed, to ensure equivalent functioning of the system during and after construction. If no drainage facilities (e.g., ditches, canals) would be affected, but project features would have a substantial significant effect on runoff amounts and/or patterns, new drainage systems will be included in the design of project alternatives to ensure that the project would not result in new or increased local flooding. Any necessary features to remediate project-induced drainage problems will be constructed before the project is completed or as part of the project, depending on site-specific conditions.

Effect FC-4: Increase in Channel Bed Incision and Bank Erosion Attributable to Heightened Levees

Flood program alternatives related to levee height are expected to provide 200-year flood protection in the study area and will contain larger floodflows within the Sacramento River channel. With no overtopping, channel flow energy potentially could increase erosion and may transfer greater energy to downstream reaches. However, considering the infrequency of flood events greater than the 200-year event, the alternatives that address levee height create little additional risk to the levee system as a whole. The levee system is not expected to provide protection for these larger flood events and is not considered in the significance assessment.

Additionally, even without program implementation, the apparent rates of incision in the second half of the 20th century and present low-water elevations, it is unlikely that further significant incision of the Sacramento River downstream of Verona would occur (Northwest Hydraulic Consultants 2007a). If any, further incision would be unlikely to exceed 1 foot or so, an amount that is negligible in comparison to potential transitory riverbed incision resulting from major floods (Northwest Hydraulic Consultants 2007a).

With respect to bank erosion, presently in the Sacramento River North and South reaches, the average velocities during the 200-year projected peak flow do not present a significant concern for surface erosion by flows parallel to the bank, except where the banks have no vegetation and no other bank protection or where significant obstructions project into the flow and generate eddies and complex flows capable of eroding the streambank (Northwest Hydraulic Consultants 2007a). The proposed alternatives would create an even more erosion-resistant levee, thus not significantly affecting bank erosion rates.

Compliance with the USACE levee vegetation guidance could increase bank erosion through loss of vegetation and disruption of soil structure. However, these effects are not considered to be significant because geotechnical stabilization of the banks would be required after vegetation removal.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full)	▪ Closure structure ▪ Setback levee ▪ Flood wall

Affected Reaches

Although different flood program alternatives are proposed for the reaches, this effect would occur in the following reaches: Sacramento River North, Sacramento River South, Port North, Port South, South Cross, DWSC East and West, and Yolo Bypass. Effects are expected to be similar or lesser in magnitude for the program reaches that are not along the Sacramento River (Port North and South Levees, South Cross Levee, DWSC East and West Levees, and Yolo Bypass Levee.

Effect FC-4 Finding	With Mitigation
Less than significant	N/A

Effect FC-5: Decrease in Levee Erosion

Portions of the levee slopes may be protected by the erosion control alternative of rock slope protection. Rock would be placed in a layer approximately 1 foot thick on the waterside of the levee to protect against erosional forces, such as wind and waves. No significant geomorphic or flood program–related effects are associated with rock slope protection, as it would provide more material with a greater resistance to erosion, thus helping to decrease relative erosion amounts. Additionally, the roughness associated with the rock slope protection would counter the increased shear stresses of larger flow events that otherwise would increase erosion of the levee fills.

In addition, rock slope protection would not result in any long-term changes to the overall existing drainage pattern of the study area. Furthermore, it would not change the existing potential for levee erosion upstream and downstream of the study area.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative
Flood	▪ Rock slope protection

Affected Reaches

Although different flood program alternatives are proposed for the reaches, this effect would occur in the following reaches: Sacramento River North, Sacramento River South, and DWSC East and West.

Effect FC-5 Finding	With Mitigation
Beneficial	N/A

Effect FC-6: Decrease in Through- and Under-Seepage

Through- and under-seepage has the potential to weaken levee foundations. Flood alternatives for seepage control such as a sheet pile wall, slurry cutoff wall, and jet grouting would reduce or eliminate the potential for seepage. Sheet pile walls and slurry cutoff walls create walls of impermeable material that act as a barrier to water moving laterally through a levee, greatly reducing or eliminating the potential for through-seepage. Similarly, jet grouting involves injecting a binding material in the soil and is typically used in areas where physical access is limited. The binding material also creates an area that is impermeable and reduces or eliminates through seepage. Similarly, the seepage berm flood program alternative results in a wide embankment structure that resists accumulated water pressure. All of these seepage control alternatives would result in beneficial effects on flood conditions in the study area.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Sheet pile wall	▪ Jet grouting
	▪ Slurry cutoff wall	▪ Seepage berm

Affected Reaches

Although different flood program alternatives are proposed for the reaches, this effect would occur in the following reaches: Sacramento River North, Sacramento River South, Port South, South Cross, DWSC East and West, Sacramento Bypass, and Yolo Bypass.

Effect FC-6 Finding	With Mitigation
Beneficial	N/A

Effect FC-7: Transfer of Seepage to Upstream or Downstream Levees

Installation of flood program alternatives that reduce seepage (e.g., sheet pile walls, slurry cutoff walls, jet grouting, or seepage berms) may have a slight effect on the potential for seepage to occur through levee sections immediately upstream or downstream, due to redirection of hydraulic force.

However, the change in hydrologic conditions resulting from these treatments is not expected to result in a substantial increase in seepage through or under adjacent levees because any upstream or downstream levee will be engineered appropriately to an equal level of protection. Incremental improvements to the system will be made over a period of years and these improvements would reduce or eliminate any seepage problems.

The alternatives are also not expected to have an effect on upstream or downstream water surface elevations because the height of the levee would not be increased and current seepage rates do not contribute to substantial reductions in channel flows or water surface elevations.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Sheet pile wall	▪ Jet grouting
	▪ Slurry cutoff wall	▪ Seepage berm

Affected Reaches

Although different flood program alternatives are proposed for the reaches, this effect would occur in the following reaches: Sacramento River North, Sacramento River South, Port South, South Cross, DWSC East and West, Sacramento Bypass, and Yolo Bypass.

Effect FC-7 Finding	With Mitigation
Less than significant	N/A

Effect FC-8: Increase in Levee Slope Stability

The flood program alternatives such as slope flattening, stability berms and setback levees can result in increased levee slope stability.

Slope flattening is a mechanical method to place additional fill material along the slope of a levee to repair and reshape slopes that may not be stable or to meet the requirement of 3:1 (H:V). A stability berm is typically constructed against the landside slope of the levee and acts as a buttress to stabilize slopes.

A setback levee is an entirely new section of levee (built utilizing the appropriate slope ratios) constructed at some distance landside of the existing levee. The existing levee (typically with geometry that does not meet current standards) can remain in place, be lowered, breached at several locations, or removed, dependent upon conditions within that levee reach. A setback levee would result in increased levee slope stability in the reach where it is constructed. No significant geomorphic or flood program–related effects are associated with a setback levee.

Treatments that increase levee slope stability would have beneficial effects on geomorphic and flood conditions.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Slope flattening ▪ Setback levee	▪ Stability berm

Affected Reaches

Although different flood program alternatives are proposed for the reaches, this effect would occur in the following reaches: Sacramento River North, Sacramento River South, Port South, South Cross, DWSC East, Sacramento Bypass, and Yolo Bypass.

Effect FC-8 Finding	With Mitigation
Beneficial	N/A

Effect FC-9: Redirection of Under-Seepage

Flood program alternatives that address under-seepage include relief wells, and interior drains. Both of these treatments provide pathways to safely capture and release under-seepage and reduce the potential for under-seepage to weaken levee foundation soils via piping or sand boils. Flood program alternatives that result in the re-direction of under-seepage would create beneficial effects on geomorphic and flood conditions.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Relief wells	▪ Interior drain

Affected Reaches

Although different flood program alternatives are proposed for the reaches, this effect would occur in the following reaches: Sacramento River South, South Cross, and DWSC East.

Effect FC-9 Finding	With Mitigation
Beneficial	N/A

Effect FC-10: Minimization of Stream Energy and Associated Floodplain Scour and/or Deposition

A setback levee is an entirely new section of levee constructed at some distance landside of the existing levee. The existing levee can remain in place, be lowered, breached at several locations, or removed, dependent upon conditions within that levee reach. No significant geomorphic or flood program–related effects are associated with a setback levee for the Sacramento River South Levee. Modeling for the setback levee as performed by MBK Engineers (Tustison pers. comm.) shows a general decrease in the water surface elevation upstream of the setback levee, while areas downstream see slightly higher water surface elevations. The slight decrease in the water surface elevation at and upstream of the setback levee associated with more floodplain capacity results in a slight increase in the flow in the Sacramento River downstream of the American River with a corresponding decrease in the flow across the Sacramento Weir (Tustison pers. comm.).

Assuming the existing levee was removed, a setback levee would provide more floodplain capacity for the Sacramento River. This increase in floodplain capacity would decrease the stream energy associated with higher flows on the river by allowing the river to access its floodplain under these higher flows. An increase in floodplain capacity represents an increase in hydraulic capacity, a beneficial effect from a flood program standpoint. Although variability in the magnitude of both floodplain scour and deposition associated with high flows is unknown, it is assumed that deposition would be the predominant geomorphic process associated with a setback levee because of the associated decrease in stream energy. Any amount of scour most likely would be limited to the upstream end. It is assumed that bank erosion on the newly reshaped bank (i.e., former levee surface) on the waterside would remain stable as features associated with this treatment would be engineered to withstand the forces of erosion by flowing water. Associated deposition of fine sediments is considered a beneficial effect as deposition would encourage natural recruitment of woody material and increase the habitat diversity on the floodplain. Furthermore, deposition of a significant amount of fine sediment in the channel is considered unlikely because the channel-forming flow regime would be unchanged.

If the existing levee were to remain in place, the effects discussed above would not occur. Floodplain capacity would remain similar to existing conditions under most flows. However, for flows greater

than the 200-year event that overtopped the existing levee, there is potential for both scour and/or deposition of fine material between the existing levee and the proposed setback levee. The amount of scour and/or deposition most likely would be small and would depend on the slope and available space between the two levees. Regardless, some scour and/or deposition would provide beneficial effects on the floodplain for reasons discussed above.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative
Flood	▪ Setback levee

Affected Reaches

This effect would occur in the Sacramento River South reach.

Effect FC-10 Finding	With Mitigation
Beneficial	N/A

Section 3.3

Water Quality and Groundwater Resources

3.3.1 Introduction

This section describes the affected environment for water quality and groundwater resources, including the regulatory setting associated with water quality and groundwater resources, the effects on water quality and groundwater resources that would result from the proposed program, and the mitigation measures that would reduce these effects.

The key sources of data and information used in the preparation of this section are listed below:

- Central Valley Regional Water Quality Control Board Water Quality Control Basin Plan (2007)
- List of water quality constituents obtained from the California Data Exchange Center website (California Data Exchange Center 2009)
- *Yolo County General Plan* (Yolo County 2002)
- *City of West Sacramento General Plan Policy Document* (City of West Sacramento 2004)
- *Solano County General Plan* (Solano County 2008)

3.3.2 Affected Environment

3.3.2.1 Regulatory Setting

3.3.2.1.1 Federal

Clean Water Act

The State Water Resources Control Board (State Water Board) is the state agency with primary responsibility for implementing the Federal Clean Water Act (CWA), which establishes regulations relating to water resource issues. Typically, all regulatory requirements are implemented by the State Water Board through nine regional water quality control boards (RWQCBs) established throughout the state. The Central Valley RWQCB is responsible for regulating discharges to the Sacramento River and its tributaries.

The CWA is the primary Federal law that protects the quality of the nation's surface waters, including lakes, rivers, and coastal wetlands. It operates on the principle that all discharges into the nation's waters are unlawful unless specifically authorized by a permit. Permit review is the CWA's primary regulatory tool. The following sections provide additional details on specific sections of the CWA.

Section 404: Permits for Fill Placement in Waters and Wetlands

CWA Section 404 regulates the discharge of dredged and fill materials into "waters of the United States," which include oceans, bays, rivers, streams, lakes, ponds, and wetlands. Project proponents

must obtain a permit from USACE for all discharges of dredged or fill material into waters of the United States before proceeding with a proposed activity. Before any actions that may affect surface waters are implemented, a delineation of jurisdictional waters of the United States must be completed, following USACE protocols, to determine whether the project area contains wetlands or other waters of the United States that qualify for CWA protection. These areas include:

- sections within the OHWM of a stream, including non-perennial streams with a defined bed and bank and any stream channel that conveys natural runoff, even if it has been realigned; and
- seasonal and perennial wetlands, including coastal wetlands.

Wetlands are defined for regulatory purposes as areas "inundated or saturated by surface or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions" (33 CFR 328.3, 40 CFR 230.3).

Applicants must obtain a permit from USACE for all discharges of dredged or fill material into waters of the United States, including wetlands, before proceeding with a proposed activity. As stated by the Counsel for the EPA's January 19, 2001, determination in response to the Solid Waste Agency of Northern Cook County *v.* U.S. Army Corps of Engineers ruling, non-navigable, isolated waters may not be regulated by USACE. As part of the wetland delineation and verification process, USACE will determine whether the wetlands in the program area are isolated and therefore not regulated under Section 404.

USACE may issue either an individual permit evaluated on a case-by-case basis or a general permit evaluated at a program level for a series of related activities. General permits are pre-authorized and are issued to cover multiple instances of similar activities expected to cause only minimal significant environmental effects. Nationwide permits (NWPs) are a type of general permit issued to cover particular fill activities. Each NWP specifies particular conditions that must be met for the NWP to apply to a particular project. Potential waters of the United States in the program area are under the jurisdiction of USACE's Sacramento District.

Compliance with Section 404 requires compliance with several other environmental laws and regulations. USACE cannot issue an individual permit or verify the use of a general permit until the requirements of NEPA, the Federal Endangered Species Act (ESA), and National Historic Preservation Act (NHPA) (see Section 3.18, Cultural Resources) have been met. In addition, USACE cannot issue or verify any permit until a water quality certification or a waiver of certification has been issued pursuant to CWA Section 401.

Certain activities are exempt from the Section 404 permitting process:

- farming, ranching, and forestry activities that are considered normal and ongoing (as of 1985 conditions), such as plowing, harvesting, and minor drainage of upland areas to waters of the United States;
- construction and maintenance of stock ponds and irrigation ditches;
- maintenance of drainage ditches;
- construction of temporary sedimentation basins in upland areas;
- construction and maintenance of farm, forest, and mining roads in accordance with BMPs; and

- other activities regulated by an approved program of BMPs authorized by CWA Section 208(b)(4).

Section 404 permits may be issued for only the least environmentally damaging practical alternative (i.e., authorization of a proposed discharge is prohibited if there is a practical alternative that would have fewer significant effects and lacks other significant consequences). Section 404 may apply to the proposed program if construction would occur within waters of the United States.

Section 402: Permits for Discharge to Surface Waters

CWA Section 402 regulates discharges to surface waters through the NPDES program, administered by EPA. In California, the State Water Board is authorized by EPA to oversee the NPDES program through the RWQCBs (see related discussion in this section under Porter-Cologne Water Quality Control Act). The NPDES program provides for both general permits (those that cover a number of similar or related activities) and individual permits.

Construction Activities

Most construction activities that disturb 1 acre of land or more are required to obtain coverage under the NPDES General Permit for Construction Activities (General Construction Permit), which requires the applicant to file a notice of intent (NOI) to discharge stormwater and to prepare and implement a SWPPP. The SWPPP includes a site map and a description of proposed construction activities, along with a demonstration of compliance with relevant local ordinances and regulations, and an overview of the BMPs that would be implemented to prevent soil erosion and discharge of other construction-related pollutants that could contaminate nearby water resources. Permittees are further required to conduct annual monitoring and reporting to ensure that BMPs are correctly implemented and effective in controlling the discharge of stormwater-related pollutants. The City will need to file an NOI with the Central Valley RWQCB to obtain the General Construction Permit before any construction activities begin.

Dewatering Activities

While small amounts of construction-related dewatering are covered under the General Construction Permit, the Central Valley RWQCB has also adopted a General Order for Dewatering and Other Low Threat Discharges to Surface Waters (General Dewatering Permit). This permit applies to various categories of dewatering activities and likely would apply to the proposed program, if construction required dewatering in greater quantities than that allowed by the General Construction Permit and discharged the effluent to surface waters. The General Dewatering Permit contains waste discharge limitations and prohibitions similar to those in the General Construction Permit. To obtain coverage, the applicant must submit an NOI and pollution prevention and monitoring program (PPMP) to the Central Valley RWQCB. The PPMP must include a description of the discharge location, discharge characteristics, primary pollutants, receiving water, treatment systems, spill prevention plans, and other measures necessary to comply with discharge limits. A representative sampling and analysis program must be prepared as part of the PPMP and implemented by the permittee, along with recordkeeping and quarterly reporting requirements during dewatering activities. For dewatering activities that are not covered by the General Dewatering Permit, an individual NPDES permit and waste discharge requirements (WDRs) must be obtained from the Central Valley RWQCB. However, the amount of dewatering needed for the proposed program likely would fall under the General Dewatering Permit because excavation

activities associated with construction of the program elements such as the slurry cutoff walls and sheet pile walls may reach the groundwater table.

Section 401: Water Quality Certification

Under CWA Section 401, applicants for a Federal license or permit to conduct activities that may result in the discharge of a pollutant into waters of the United States must obtain certification from the state in which the discharge would originate or, if appropriate, from the interstate water pollution control agency with jurisdiction over affected waters at the point where the discharge would originate. Therefore, all projects that have a Federal component and may affect the quality of the state's waters (including projects that require Federal agency approval, such as the issuance of a Section 404 permit) also must comply with Section 401. The City will obtain a Section 401 certification or waiver from the Central Valley RWQCB.

Section 303: Impaired Waters

California adopts water quality standards to protect beneficial uses of state waters as required by CWA Section 303 and the Porter-Cologne Water Quality Control Act of 1969. Under Section 303(d) of the CWA, states, territories, and authorized tribes are required to develop a list of water quality-limited segments. In California, the State Water Board develops the list of water quality-limited segments; the EPA approves each state's list. Waters on the list do not meet water quality standards, even after point sources of pollution have installed the minimum required levels of pollution control technology. Section 303(d) also establishes the total maximum daily load (TMDL) process to guide the application of state water quality standards.

3.3.2.1.2 State

Porter-Cologne Water Quality Control Act

The Porter-Cologne Water Quality Control Act, passed in 1969, articulates with the CWA. It established the State Water Board and divided the state into nine regions, each overseen by an RWQCB. The State Water Board is the primary state agency responsible for protecting the quality of the state's surface and groundwater supplies, although much of its daily implementation authority is delegated to the RWQCBs, which are responsible for implementing CWA Sections 402 and 303(d). In general, the State Water Board manages both water rights and statewide regulation of water quality, while the RWQCBs focus exclusively on water quality within their regions.

Central Valley Regional Water Quality Control Board

The Central Valley RWQCB is responsible for implementing its Water Quality Control Plan (Basin Plan) (2007) for the Sacramento River and its tributaries. The Basin Plan identifies beneficial uses of the river and its tributaries and water quality objectives to protect those uses. Numerical and narrative criteria are contained in the Basin Plan for several key water quality constituents, including dissolved oxygen (DO), water temperature, trace metals, turbidity, suspended material, pesticides, salinity, radioactivity, and other related constituents.

The methods the Central Valley RWQCB uses to implement the Basin Plan criteria include issuing WDRs. WDRs are issued to any entity that discharges to a surface water body and does not meet certain water quality criteria such as those related to sediment. The WDR/NPDES permit also serves

as a federally required NPDES permit (under the CWA) and incorporates the requirements of other applicable regulations.

Basin Plans and Water Quality Objectives

The Porter-Cologne Water Quality Control Act provides for the development and periodic review of basin plans that designate beneficial uses of California's major rivers and groundwater basins and establish narrative and numerical water quality objectives for those waters. Beneficial uses represent the services and qualities of a water body (i.e., the reasons the water body is considered valuable), while water quality objectives represent the standards necessary to protect and support those beneficial uses. Basin plans are implemented primarily by using the NPDES permitting system to regulate waste discharges so that water quality objectives are met (see discussion of the NPDES system under CWA above). Basin plans are updated every 3 years and provide the technical basis for determining WDRs and taking enforcement actions. The Central Valley RWQCB Basin Plan was last updated in 2007.

Water Quality Objectives by Region

The RWQCBs have set water quality objectives for all surface waters in their respective regions (including the Sacramento River basin) for the following substances and parameters: ammonia, bacteria, biostimulatory substances, chemical constituents, color, DO, floating material, oil and grease, pH, pesticides, radioactivity, salinity, sediment, settleable material, suspended material, tastes and odors, temperature, toxicity, and turbidity.

State Implementation Plan

In 1994, the State Water Board and EPA agreed to a coordinated approach for addressing priority toxic pollutants in inland surface waters, enclosed bays, and estuaries of California. In March 2000, the State Water Board adopted a state implementation plan (SIP) for priority toxic pollutant water quality criteria contained in the California Toxics Rule (CTR). EPA promulgated the CTR in May 2000. The SIP also implements National Toxics Rule (NTR) criteria and applicable priority pollutant objectives in the basin plans. In combination, the CTR and NTR and applicable basin plan objectives, existing RWQCB beneficial use designations, and SIP compose water quality standards and implementation procedures for priority toxic pollutants in non-ocean surface waters in California, such as the Sacramento River.

3.3.2.1.3 Local

City of West Sacramento General Plan

The City is in the process of updating its general plan that was adopted in 1990. The Natural Resources section of the existing general plan contains a number of goals and polices related to water quality.

Goal A: To protect water quality in the Sacramento River, Sacramento Deep Water Ship Channel, Lake Washington, and the area's groundwater basin.

Policies

1. The City shall prohibit the establishment of any new septic systems within areas where City sewer and water service are available within one air mile and shall require that new septic tank installation elsewhere be limited to one acre or larger parcels.
2. The City shall seek the elimination of existing septic tanks in urbanized areas.
3. The City shall not approve new development that has a significant potential for adversely affecting water quality in the Sacramento River, the Deep Water Ship Channel, Lake Washington, or the area's groundwater basin.
4. The City shall regularly monitor water quality in City wells for evidence of toxics, saltwater intrusion, and other contaminants.
5. The City shall utilize the CEQA process to identify and avoid or mitigate potential groundwater pollution problems resulting from new commercial and industrial development.
6. The City shall support efforts on a county, regional, or statewide basis to reduce runoff of toxic agricultural chemicals into the Sacramento River.
7. The City shall implement measures to minimize the discharge of sediment into its watercourses.
8. The City shall continue to encourage responsible state agencies to prohibit the discharge of saltwater ballast into the Deep Water Ship Channel.

Yolo County General Plan

The *Yolo County General Plan* is also in the process of being updated, and a draft revised General Plan is available on the County website. The Conservation and Open Space Element contains goals on polices in regard to water resources. The following goal and polices are included in the Yolo County General Plan:

Goal CO-5: Water Resources. Ensure an abundant, safe, and sustainable water supply to support the needs of existing and future generations.

Policy CO-5.6. Improve and protect water quality for municipal, agricultural, and environmental uses.

Policy CO-5.7. Support mercury regulations that are based on good science and reflect an appropriate balancing of sometimes competing public values including health, food chain, reclamation and restoration of Cache Creek, sustainable and economically viable Delta agriculture, necessary mineral extraction, flood control, erosion control, water quality, and habitat restoration.

Policy CO-5.8. Support efforts to reduce the accumulation of methyl mercury in fish tissue in Cache Creek and the Delta, as well as the consumption of fish with high levels of methyl mercury.

Policy CO-5.12. Support the integrated management of surface and groundwater, stormwater treatment and use, the development of highly treated wastewater, and desalinization where feasible.

Policy CO-5.17. Require new development to be designed such that nitrates, lawn chemicals, oil, and other pollutants of concern do not impair groundwater quality.

Policy CO-5.21. Encourage the use of water management strategies, biological remediation, and technology to address naturally occurring water quality problems such as boron, mercury, and arsenic.

Policy CO-5.22. Work with other agencies and non-profit organizations to provide educational and technical assistance programs to encourage farmers to adopt agricultural methods that improve water quality.

Policy CO-5.23. Support efforts to meet applicable water quality standards for all surface and groundwater resources.

Policy CO-5.24. Pursue funding to remediate historic mines and other sources of mercury contamination on the Cache Creek watershed.

Solano County General Plan

The *Solano County General Plan* was updated in December 2008. Water quality–related polices are included in the Resources chapter of the General Plan and are as follows:

RS.P-64. Identify, promote, and seek funding for the evaluation and remediation of water resource or water quality problems through a watershed management approach. Work with the regional water quality control board, watershed focused groups, and stakeholders in the collection, evaluation and use of watershed-specific water resource information.

RS.P-65. Require the protection of natural water courses.

RS.P-70. Protect land surrounding valuable water sources, evaluate watersheds, and preserve open space lands to protect and improve groundwater quality, reduce polluted surface runoff, and minimize erosion.

RS.P-71. Ensure that land use activities and development occur in a manner that minimizes the effect of earth disturbance, erosion, and surface runoff pollutants on water quality.

RS.P-72. Preserve riparian vegetation along county waterways to maintain water quality.

RS.P-73. Use watershed planning approaches to resolve water quality problems. Use a comprehensive stormwater management program to limit the quantity and increase the water quality of runoff flowing to the county's streams and rivers.

RS.P-74. Identify naturally occurring and human-caused contaminants in groundwater in new development projects and develop methods to limit and control contaminants. Work with RWQCB to educate the public on evaluating the quality of groundwater.

RS.P-75. Require and provide incentives for site plan elements (such as permeable pavement, swales, and filter strips) that limit runoff and increase infiltration and groundwater recharge.

3.3.2.2 Environmental Setting

This section discusses the existing conditions related to surface water quality and groundwater quality in the proposed program area, which includes the Sacramento River both north and south of the city of West Sacramento. Portions of the DWSC also are included in the proposed program area.

3.3.2.2.1 Surface Water Quality

Water management operations at Shasta Dam and other flow-regulating facilities substantially influence the flow regime of the Sacramento River. Water quality dynamics also have been influenced by the operation of these flow-regulating facilities. The water quality of the Sacramento River is good to excellent, with relatively cool water temperatures, low biochemical oxygen demand (BOD), medium to high DO, and low mineral and nutrient content. In general, the surface water quality of the Sacramento River is representative of agricultural return flows, urban runoff, and natural sedimentation from scouring.

CWA Section 303(d) establishes the TMDL process to assist in guiding the application of state water quality standards. It requires the states to identify streams in which water quality is impaired (i.e., affected by the presence of pollutants or contaminants) and to establish the TMDL—the maximum quantity of a particular contaminant that a water body can assimilate without experiencing adverse effects. The 303(d) list breaks up the Sacramento River into four sections: Keswick Dam to Cottonwood Creek, Cottonwood Creek to Red Bluff, Red Bluff to Knights Landing, and Knights Landing to the Delta. All sections of the Sacramento River are listed on the 303(d) list for unknown toxicity, and the Knights Landing to the Delta section is listed for mercury. Mercury is primarily a legacy of gold mining.

The following sections discuss specific contaminants of concern in relation to the implementation of the program on the Sacramento River. Water quality data for the DWSC and Lake Washington are not available on the California Data Exchange Center (CDEC) website and the USGS website. However, water quality of the DWSC is representative of the quality of water on the Sacramento River near the confluence of the Delta.

Total Suspended Sediment and Turbidity

Total suspended sediment (TSS) is indicative of upstream scouring, bank erosion, and agricultural return flow transporting and depositing sediment. Sediment is considered a pollutant by the Central Valley RWQCB and can transport other contaminants, such as phosphorus, and hydrophobic contaminants, such as organochlorine pesticides. Data were downloaded from the USGS web site from 1997 to 2007 for the Sacramento River at Freeport. Note that more recent flow data (2007 to 2009) are available; however, there is no matching TSS data available for this more recent time frame. Therefore, the most recent available data (2007 to 2009) were used to calculate sediment loads. Monthly average data points are presented in Table 3.3-1. The average January flow on the Sacramento River from 1997 to 2007 is 41,414 cfs, and the average loading of sediment during January is equal to 11,670 (Conversion Factor*TSS*Flow/Ton) tons per day.

Although sedimentation is a natural part of the flow regime for rivers, the Central Valley RWQCB also considers it a pollutant. Excessive sedimentation from construction practices such as placement of riprap on levees or constructing slurry cutoff walls can smother filter-feeding organisms and cause other serious water quality related issues.

Turbidity is another measurement of how much sedimentation is in the water and is done using an optical light probe. Turbidity is measured in nephelometric turbidity units (NTUs). The Basin Plan states that where ambient turbidity is between 5 and 50 NTUs, projects shall not increase turbidity on the Sacramento River by more than 20% above the ambient conditions. Furthermore, if the ambient diurnal variation in turbidity fluctuates in and out of the 5 and 50 NTUs threshold, the Basin Plan states that averaging periods can be applied to data to determine compliance. For

example, during the summer months, the Sacramento River turbidity may be less than 50 NTUs, and during the winter months, the turbidity may be more than 50 NTUs because of the higher flow rate causing more river scouring. Thus monthly average was calculated using hourly CDEC data and is presented in Table 3.3-1 below. Where the ambient turbidity is between 50 and 100 NTUs, a project must not exceed 10 NTUs above ambient conditions. This threshold would apply to the months of January and February (Table 3.3-1).

Specific construction projects that are part of the proposed program will need to comply with the above-stated thresholds for turbidity. However, it is important to note that these thresholds may not be the same during the construction period because the turbidity data presented in Table 3.3-1 are averaged out over only about 1.5 years, and conditions might change.

Table 3.3-1. Monthly Average Total Suspended Solids and Turbidity on the Sacramento River at Freeport from 1997 to 2007

Month	Discharge (cfs)[1]	TSS (mg/L)[1]	TSS Load (tons)	Turbidity (NTU)[2]
January	41,414	104	11,670	64
February	44,084	83	9,839	68
March	39,586	70	7,476	15
April	28,552	51	3,946	11
May	25,152	48	3,279	12
June	21,461	30	1,741	17
July	20,432	37	2,019	21
August	18,235	27	1,332	9
September	16,121	29	1,266	10
October	11,950	29	940	6
November	13,612	24	868	8
December	25,105	81	5,463	12

[1] U.S. Geological Survey (USGS) data: <www.usgs.gov>.

[2] California Data Exchange Center (CDED) data: <http://cdec.water.ca.gov>.

Notes:

Flow and TSS data are from the USGS and are presented as monthly average from 1997 to 2007. Turbidity data are from CDEC from March 2007 to January 2009 and also are presented as a monthly average. Turbidity data are from the Sacramento River at Hood, a few river miles downstream from the USGS station.

Dissolved Oxygen, Temperature, Electrical Conductivity, and pH

DO is a critical component for all forms of aquatic life. It also can be highly variable and subject to large oscillations in short time periods. With calm waters and low flows, water bodies can thermally stratify, causing deeper zones to have very low DO concentrations. Additionally, high levels of nutrient loading can cause algal blooms. These blooms can cause large swings in DO levels as the algae populations fluctuate in size, producing oxygen while growing and consuming it while decaying. When DO concentrations fall below certain limits, the resulting low-DO zones can act as a barrier to fish migration and potentially adversely affect spawning success. In extreme cases, persistent low concentrations of DO can result in mortality of benthic organisms and other less-

mobile aquatic species. The Basin Plan objective for DO in the Sacramento River from the I Street Bridge to the Delta is 7.0 milligrams per liter (mg/L) (Central Valley Regional Water Quality Control Board 2007). The Sacramento River DO concentrations near Hood from 2003 to 2009 are typically 10 mg/L during the storm season and 8 mg/L or more during the dry season when flow is lower (Table 3.3-2).

Water temperature is a critical constituent from the standpoint of aquatic life. The Basin Plan objective requires that the Sacramento River temperature not exceed 68°F from Hamilton City to the I Street Bridge in Sacramento during periods when temperature increases would be detrimental to the fishery. In addition, the Basin Plan objective for temperature also requires that it not deviate more than 5°F from ambient river temperature (Central Valley Regional Water Quality Control Board 2007). During the summer months of July and August, the temperature of the Sacramento at Hood was approximately 71°F (Table 3.3-2). However, this location is downstream of the I Street Bridge, and with the cold water inflow of the American, the I Street Bridge temperature may be within Basin Plan standards. While an unlikely scenario, excessive sedimentation in large quantities could affect the temperature of the Sacramento River.

The potential of hydrogen (pH) is a unit for measuring the concentration of hydrogen ion activity in water and is reported on a scale from 0 to 14. If a solution measures less than 7, it is considered acidic. If a solution measures more than 7, it is considered basic, or alkaline. If a solution measures 7, it is considered neutral. Many biological functions can occur only within a narrow range of pH values. The Basin Plan objective for pH is between 6.5 and 8.5. Furthermore, discharges cannot result in changes of pH that exceed 0.5. The monthly average pH of the Sacramento River from 2003 to 2009 remained stable throughout the year (Table 3.3-2). Construction materials such as concrete or other chemicals could affect the pH of the Sacramento River if a discharge were to occur.

Electrical conductivity (EC) is a measure of the degree to which a given water sample conducts an electrical current. The amount of total dissolved solids (TDS) in water is related directly to EC (i.e., high EC is an indicator of high TDS). TDS and EC are general indicators of salinity and are regulated under the Basin Plan. Basin Plan objectives for EC on the Sacramento River are 340 microSiemens per centimeter (µS/cm). It is clear in Table 3.3-2 that monthly average EC levels in the Sacramento River remain below this threshold.

Table 3.3-2. Monthly Average Physical Data for the Sacramento River at Freeport from 2003 to 2009

Month	Temperature (°F)	pH (Standard)	DO (mg/L)	EC (µs/cm)
January	48.7	7.5	10.5	170
February	50.9	7.4	10.1	170
March	55.3	7.5	9.7	154
April	58.3	7.4	9.6	138
May	64.3	7.4	8.6	145
June	68.8	7.3	8.2	139
July	71.1	7.3	7.9	134
August	71.0	7.4	7.8	156
September	67.9	7.5	8.0	166
October	62.5	7.2	8.6	145
November	55.9	7.4	8.9	186
December	49.5	7.4	10.2	186

Groundwater Resources Quality

DWR delineates groundwater basins throughout California under the state's Groundwater Bulletin 118. The WSLIP is located in the Sacramento Valley Groundwater Basin, Yolo Sub-basin (Basin No. 5-21.67). The total surface area of the Yolo Sub-basin is 256,000 acres. The Yolo Sub-basin is bounded on the east by the Sacramento River, on the west by the Coast Range, on the north by Cache Creek, and on the south, by Putah Creek. The sub-basin is roughly bisected by an anticlinal structure, but otherwise it is gently sloping from west to east with elevations ranging from 400 feet at the base of the Coast Range, to close to sea level near the eastern portion of the sub-basin (California Department of Water Resources 2004).

Younger alluvium in the sub-basin consists of flood basin deposits and recent stream channel deposits. Flood basin deposits occur along the eastern margin of the sub-basin. The deposits consist of silts and clay, but along the eastern portion of the sub-basin, the interbedded deposits are connected with deposits of the Sacramento River. Older alluvium generally consists of loose to moderately compacted silt, silty clay, sand, and gravel deposited in alluvial fans during the Pliocene and Pleistocene (California Department of Water Resources 2004).

The anticlinal structure, which is expressed at the surface as the Dunnigan Hills and Plainfield Ridge, impedes subsurface flow from east to west. Subsurface groundwater outflow sometimes occurs from the Yolo Sub-basin into the Solano Sub-basin to the south. Subsurface outflow and inflow also may occur beneath the Sacramento River (California Department of Water Resources 2004).

Groundwater levels in the sub-basin are affected by periods of drought, a result of increased groundwater pumping and less surface water recharge. However, data indicate that the recovery of the aquifer is fast during wet years. Data indicate that long-term trends do not show any significant groundwater decline (California Department of Water Resources 2004). However, there are localized groundwater depressions in the vicinity of the Davis, Woodland, and Dunnigan/Zamora areas. Past studies have shown that the Yolo Sub-basin is subject to overdraft; however, the completion of Indian Valley Reservoir in 1976 provided a significant amount of surface water deliveries to be blended with groundwater in the urbanized areas located in the sub-basin (California Department of Water Resources 2004).

Many studies have been conducted to determine the groundwater storage capacity of the sub-basin. Several of these studies refer to Scott and Scalmanini in their 1975 report, *Investigations of Groundwater Resources, Yolo County*. Groundwater storage capacity for the Yolo Sub-basin can be estimated at 6,455,940 acre-feet for the depths between 20 and 420 feet. Based on the Scott report, groundwater storage in the Yolo Sub-basin in 1974 was estimated at 6,074,220 acre-feet (California Department of Water Resources 2004).

Groundwater quality in the sub-basin is characterized as a sodium magnesium, calcium magnesium, or magnesium bicarbonate type. The quality is considered good for both agricultural and municipal uses, despite the elevated hardness in the basin. The hardness is generally above 180 mg/L calcium carbonate ($CaCO_3$). Selenium and boron are found in high concentrations locally (California Department of Water Resources 2004). TDS range from 107 parts per million (ppm) to 1,300 ppm and average 574 ppm based on Title 22 data obtained from public supply wells (California Department of Water Resources 2004). Localized impairments include elevated concentrations of boron (as high as 2 to 4 ppm) in groundwater along Cache Creek and the Cache Creek Settling Basin area, increased levels of selenium present in groundwater supplies for the city of Davis, and localized areas of nitrate contamination (California Department of Water Resources 2004). Along

the Sacramento River North Levee near Riverbank Road, Bryte Park, and The Rivers site, there is a known groundwater petroleum plume that will be affected by construction activities for The Rivers EIP project. The effects from this construction are evaluated below under The Rivers EIP Environmental Consequences section.

3.3.3 Environmental Consequences

This section describes the environmental consequences relating to surface water quality and groundwater quality for the proposed program. It describes the methods used to determine the effects of the program and lists the thresholds used to conclude whether an effect would be significant. Measures to mitigate (i.e., avoid, minimize, rectify, reduce, eliminate, or compensate for) significant effects accompany each effect discussion. How effects differ among reaches is discussed as applicable.

3.3.3.1 Assessment Methods

This evaluation of surface water quality and groundwater quality is based on professional standards and information obtained from the Central Valley RWQCB, State Water Board, and DWR. The water quality data obtained from USGS and CDEC were used to determine baseline comparative water quality conditions in the Sacramento River and DWSC.

The key effects were identified and evaluated based on the physical characteristics of the program area and the magnitude, intensity, and duration of activities related to the construction projects that are part of this program.

3.3.3.2 Determination of Effects

For this analysis, an effect pertaining to surface water quality and groundwater quality was considered analyzed under CEQA and NEPA if it would result in any of the following environmental effects, which are based on professional practice and State CEQA Guidelines Appendix G (14 CCR 15000 *et seq.):*

- violate water quality standards or waste discharge requirements;
- substantially deplete groundwater supplies or interfere substantially with ground water recharge;
- substantially degrade water quality; and
- alter regional or local hydrology resulting in substantial increases in erosion or sedimentation.

3.3.3.3 Effects and Mitigation Measures

3.3.3.3.1 No Action Alternative

To recap from Chapter 2, Alternatives, the No Action Alternative is the continuation of the existing deficiencies along the nine levee reaches and absence of levee alternatives to increase the level of protection. Current levee operations and maintenance would continue. No construction-related effects relating to water quality such as earthmoving that result in increased turbidity, or incidental

releases of construction-related contaminants would occur. Therefore, there would be no effect on surface or groundwater quality resources attributable to the implementation of the No Action Alternative.

However, without levee improvements, there is the continued risk of levee failure and continuing under seepage and loss of levee foundation soils would be expected to continue. If a levee overtopping or breach were to occur, floodwaters could be pumped back over levees or recede back through the levee breach into the Sacramento River, DWSC, or the Yolo or Sacramento Bypasses. Flooded areas may contain contaminants from stored chemicals, septic systems, and flooded vehicles—all of which would be released into floodwaters and subsequently contaminate the Sacramento River and the Delta surface waters and potentially soil and groundwater. These contaminants would likely exceed acceptable established water quality standards and impair beneficial uses of the Sacramento River and Delta, including downstream drinking water intakes. A catastrophic levee failure could result in collapse of miles of levee slopes and alteration of regional and local hydrology that would result in substantial increases in erosion and sedimentation. Loss of eroded levee foundation and eroded topsoil from inundated areas would increase turbidity and total dissolved solids in the Sacramento River and ultimately, the Delta; again, impairing beneficial uses. Furthermore, if a levee breach were to occur, emergency construction and repair activities would be implemented without the use of best management practices and could result in the release of hazardous construction materials such as oil and other petroleum related products.

3.3.3.3.2 Flood and Recreation Program Alternatives

Effect WQ-1: Effects on Surface Water Quality from Excessive Turbidity or Total Suspended Solids

Program actions would require construction-related earth-disturbing activities that potentially cause erosion and sedimentation to adjacent water bodies according to levee reach. Some flood program alternatives could cause greater erosion in comparison with others. For example, the full levee raise involves the greatest amount of earth-disturbing activity and placement of embankment fill material and, as a result, could cause more erosion than the adjacent levee raise. Furthermore, some activities such as rock slope protection or slope flattening may require in-water work that could result in greater sedimentation and increased turbidity in comparison to flood control activities that are primarily landside. Because this type of construction would occur close to the Sacramento River, DWSC, Yolo or Sacramento Bypass, depending on the reach, sedimentation and turbidity could occur in those water bodies. Two environmental commitments (see Section 2.9 of Chapter 2, Alternatives) are included in the program that would reduce the likelihood that this effect would occur, or reduce the effect should it occur. These commitments include the development of the SWPPP and monitoring of turbidity during construction activities. Site-specific erosion control measures would be developed as part of a SWPPP, a requirement of the NPDES General Construction Permit. A SWPPP typically contains, but is not limited to, the following described best management practices:

- **Timing of construction.** Conduct earthwork during the typical construction season.
- **Staging of construction equipment and materials.** Stage construction equipment and materials on the landside of the subject levee reaches. To the extent possible, stage equipment and materials in areas that already have been disturbed.

- **Soil and vegetation disturbance.** Minimize ground and vegetation disturbance during construction by establishing designated equipment staging areas, ingress and egress corridors, spoils disposal and soil stockpile areas, and equipment exclusion zones prior to the commencement of any grading operations.
- **Grading spoils.** Stockpile soil and grading spoils on the landside of the subject levee reaches, and install sediment barriers (e.g., silt fences, fiber rolls, straw bales) around the base of stockpiles to intercept runoff and sediment during storm events. If necessary, cover stockpiles with geotextile fabric to provide protection against wind and water erosion.
- **Sediment barriers.** Install sediment barriers on graded or otherwise-disturbed slopes as needed to prevent sediment from leaving the project site and entering nearby surface waters.
- **Site stabilization.** Install native plant materials to stabilize cut and fill slopes and other disturbed areas once construction is complete. Plant materials may include an erosion control seed mixture or shrub and tree container stock. Temporary structural BMPs, such as sediment barriers, erosion control blankets, mulch, and a mulch tackifier, may be installed as needed to stabilize disturbed areas until vegetation becomes established.

As part of a turbidity monitoring program, the city or its contractor will monitor turbidity in the adjacent water bodies, where applicable criteria apply, to determine whether turbidity is being affected by construction and ensure that construction does not result in a rise in turbidity levels above ambient conditions, in accordance with the Central Valley RWQCB Basin Plan turbidity objectives. The monitoring program will include monitoring ambient turbidity conditions upstream and 200 feet downstream of construction activities. Grab samples will be collected at a downstream location that is representative of the flow near the construction site. If there is a visible sediment plume being created from construction, the sample should represent this plume. Monitoring should occur hourly when construction encroaches into the Sacramento River. If construction does not encroach into the river, the monitoring should occur once a week on a random basis.

If turbidity limits exceed Basin Plan standards, construction-related earth-disturbing activities will slow to a point that results in alleviating the problem. WSAFCA or its contractor will notify the Central Valley RWQCB of the issue and provide an explanation of the cause. The implementation of these environmental commitments would reduce any potential effects to a less-than-significant level.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall ▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Closure structure ▪ Interior drain ▪ Jet grouting ▪ Relief wells	▪ Seepage berm ▪ Sheet pile wall ▪ Slurry cutoff wall ▪ Slope flattening ▪ Stability berm ▪ Rock slope protection ▪ Setback levee ▪ Vegetation removal
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect would occur in all nine program reaches. The extent of this effect could be greater at those reaches where both flood and recreation program alternatives would be implemented, i.e., the Sacramento River North and South Levees, Port North and South Levees, South Cross Levee, DWSC East Levee, and Yolo and Sacramento Bypass Levees. There is an unnamed drainage ditch that runs the length of the South Cross levee and a small forebay and pump station on the easternmost side near the DWSC; water is pumped from the drainage ditch to the DWSC. Therefore, any effects on water quality to the unnamed drainage ditch could result in indirect effects on the DWSC.

Effect WQ-1 Finding	With Mitigation
Less than significant	N/A

Effect WQ-2: Release of Contaminants into Adjacent Surface Water Bodies from Construction-Related Hazardous Materials

Program actions may involve storage, use, or discharge of toxic and other harmful substances near the Sacramento River and other water bodies (or in areas that drain to these water bodies). Construction activities would involve the use of heavy equipment, cranes, compactors and other construction equipment that uses petroleum products (e.g., fuels, lubricants, hydraulic fluids, coolants). All of these materials may be toxic to fish and other aquatic organisms. An accidental spill or inadvertent discharge of these materials could affect the water quality of the river or water body.

For some flood alternatives there could be greater potential for construction-related hazardous materials to enter adjacent water bodies. For example, rock slope protection requires an excavator to place riprap into the adjacent water body, therefore the proximity of construction equipment to the water would be closer than it would be for an adjacent levee raise.

There are three environmental commitments included in the program that would reduce the effect of such a release should it occur or reduce the likelihood that a release would occur. These environmental commitments include the development of the SWPPP, SPCCP and a bentonite slurry spill contingency plan (BSSCP). Typical elements of the SWPPP are described above under Effect WQ-1. All three environmental commitments are described in detail in Section 2.9 of Chapter 2, Alternatives, and are summarized below.

An SPCCP is intended to prevent any discharge of oil into navigable water or adjoining shorelines. WSAFCA or its contractor will develop and implement an SPCCP to minimize the potential for and effects from spills of hazardous, toxic, or petroleum substances during construction and operation activities. The SPCCP will be completed before any construction activities begin. Implementation of this measure will comply with state and Federal water quality regulations. The SPCCP will describe spill sources and spill pathways in addition to the actions that would be taken in the event of a spill (e.g., an oil spill from engine refueling would be immediately cleaned up with oil absorbents). The SPCCP will outline descriptions of containments facilities and practices such as doubled-walled tanks, containment berms, emergency shut-offs, drip pans, fueling procedures and spill response kits. It will also describe how and when employees are trained in proper handling procedure and spill prevention and response procedures.

A BSSCP is typically developed for activities that involve the use of bentonite materials (e.g., the construction of slurry walls). The BSSCP is intended to minimize the potential for a frac-out associated with excavation and tunneling activities, provide for timely detection of frac-outs, and ensure and "minimum-effect" response in the event of a frac-out and release of excavation fluid (i.e., bentonite used for the construction of slurry walls).

Release of contaminants into adjacent water bodies could result in significant effects. Adherence to these environmental commitments and the implementation of Mitigation Measure WQ-MM-1 should spills occur would reduce this effect to less than significant.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall ▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Closure structure ▪ Interior drain ▪ Jet grouting ▪ Relief wells	▪ Seepage berm ▪ Sheet pile wall ▪ Slurry cutoff wall ▪ Slope flattening ▪ Stability berm ▪ Rock slope protection ▪ Setback levee ▪ Vegetation removal
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect would occur in all nine program reaches. There is an unnamed drainage ditch that runs the length of the South Cross levee and a small forebay and pump station on the easternmost side near the DWSC; water is pumped from the drainage ditch to the DWSC. Therefore, any effects on water quality to the unnamed drainage ditch could result in indirect effects on the DWSC.

Effect WQ-2 Finding	With Mitigation
Significant	Less than significant

Mitigation

Mitigation Measure WQ-MM-1: Implement Measures to Maintain Surface Water Quality and Groundwater Quality

If an appreciable spill has occurred and results determine that program activities have significantly affected surface or groundwater quality, a detailed analysis will be performed by a registered environmental assessor or professional engineer to identify the likely cause of contamination. This analysis will conform to American Society for Testing and Materials (ASTM) standards and will include recommendations for reducing or eliminating the source or mechanisms of contamination.

Based on this analysis, the City and its contractors will select and implement measures to control contamination, with a performance standard that surface water quality and groundwater quality must be returned to baseline conditions.

Effect WQ-3: Effects on Groundwater or Drinking Water Quality Resulting from Construction and Operation

Trenching and excavation associated with all of the flood alternatives (particularly slurry walls) may reach a depth that could expose the water table, in which case an immediate and direct path to the groundwater basin would become available for contaminants to enter the groundwater system. Alternatively, if an adjacent water body (e.g., the Sacramento River) is encroached during grading, a direct path would be created for contaminants to transfer to the groundwater table and vice versa. Primary construction-related contaminants that could reach groundwater include increased sediment, oil and grease, and hazardous materials.

In addition, while dewatering of the construction area (e.g., trenches dug for slurry wall construction that may be filled with groundwater) is not expected to occur to implement the flood program alternatives, if it became necessary, it could result in the release of contaminants to surface or groundwater.

Currently there is a known groundwater contaminated area near The Rivers EIP project area (Figure 3.3-1). The plume is a result of the operation of petroleum-related refueling activities by DWR. DWR is currently monitoring the plume to determine the flow patterns of the plume and to ensure minimal effects on any drinking water wells in the area. There are no other known groundwater contaminated plumes in the program area. The leaking storage tanks were discovered in 1994 and have since been fixed (California Department of Water Resources 2009). More detail on this plume is discussed below in Section 3.3.5.3, The Rivers EIP Environmental Consequences section.

The implementation of flood and recreation program alternatives is not expected to require digging or trenching at depths where groundwater aquifers utilized for drinking water occur. The alternative that may require the greatest depth of trenching or digging is the slurry wall. If trenching activities were to incidentally reach a groundwater aquifer utilized for drinking water, the slurry wall material is relatively benign and would not remain in a liquid state long enough to allow for significant lateral movement within the aquifer.

As discussed in Section 3.17, Public Health and Hazards, prior to all construction activities, the WSAFCA will complete Phase I and, if necessary, Phase II Environmental Site Assessment Investigations that will include analysis of soil and/or groundwater samples for the potential contamination sites that have not yet been covered by previous investigations. If hazardous substances are found, WSAFCA or its contractor will implement required measures for the proper transport and disposal of such materials in accordance with the appropriate local, state and Federal laws and regulations.

Effect on groundwater and drinking water quality from operation and construction could be significant. The proposed program would adhere to environmental commitments of the SWPPP, the SPCCP, and the BSSCP, as summarized above under Effects WQ-1 and WQ-2. Adherence to those environmental commitments and the implementation of Mitigation Measures WQ-MM-1 and WQ-MM-2 would reduce this effect to less than significant.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall ▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Closure structure ▪ Interior drain ▪ Jet grouting ▪ Relief wells	▪ Seepage berm ▪ Sheet pile wall ▪ Slurry cutoff wall ▪ Slope flattening ▪ Stability berm ▪ Setback levee ▪ Vegetation removal
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect would affect all nine program reaches.

Effect WQ-3 Finding	With Mitigation
Significant	Less than significant

Mitigation

Mitigation Measure WQ-MM-1 Implement Measures to Maintain Surface Water Quality and Groundwater Quality

Mitigation Measure WQ-MM-2: Implement Provisions for Dewatering

Before discharging any dewatered effluent to surface water, the City or its contractors will obtain a Low Threat Discharge and Dewatering NPDES permit from the Central Valley RWQCB. Depending on the volume and characteristics of the discharge, coverage under the Central Valley RWQCB's NPDES General Construction Permit or General Dewatering Permit is possible. As part of the permit, the permittee will design and implement measures as necessary so that the discharge limits identified in the relevant permit are met. For example, if dewatering is needed during the construction of the slurry wall at The Rivers EIP project area, then the Low Threat Discharge and Dewatering NPDES permit would require proper disposal of the water due to the known petroleum plume present in the area. As a performance standard, these measures will be selected to achieve maximum sediment removal and represent the best available technology that is economically achievable. Implemented measures may include the retention of dewatering effluent until particulate matter has settled before it is discharged, use of infiltration areas, and other BMPs. Final selection of water quality control measures will be subject to approval by the City.

The City will verify that coverage under the appropriate NPDES permit has been obtained before allowing dewatering activities to begin. The City or its agent will perform routine inspections of the construction area to verify that the water quality control measures are properly implemented and

Section 3.4

Geology, Seismicity, Soils, and Mineral Resources

3.4.1 Introduction

This section describes the regulatory and environmental setting for geology, seismicity, soils, and mineral resources; the effects on geology, soils, and mineral resources that would result from the program; and the mitigation measures that would reduce these effects.

The key sources of data and information used in the preparation of this section are listed and briefly described below.

- Maps and reports prepared by the USGS, California Geological Survey, Natural Resources Conservation Service, and the California Division of Mines and Geology
- *Yolo County General Plan* (Yolo County 2002)
- *Solano County General Plan* (Solano County 2008)
- *City of West Sacramento General Plan* (City of West Sacramento 2004a)
- *Problem Identification Report* (HDR, Inc. on behalf of the City of West Sacramento 2008)

3.4.2 Affected Environment

3.4.2.1 Regulatory Setting

3.4.2.1.1 State

Alquist-Priolo Earthquake Fault Zoning Act

California's Alquist-Priolo Earthquake Fault Zoning Act (Alquist-Priolo Act) (Public Resources Code [PRC] Section 2621 *et seq.*), originally enacted in 1972 as the Alquist-Priolo Special Studies Zones Act and renamed in 1994, is intended to reduce the risk to life and property from surface fault rupture during earthquakes. The act prohibits the location of most types of structures intended for human occupancy across the traces of active faults and strictly regulates construction in the corridors along active faults (earthquake fault zones). It also defines criteria for identifying active faults, giving legal weight to terms such as *active*, and establishes a process for reviewing building proposals in and adjacent to earthquake fault zones.

Under the Alquist-Priolo Act, faults are zoned, and construction along or across faults is strictly regulated if they are sufficiently active and well defined. A fault is considered sufficiently active if one or more of its segments or strands shows evidence of surface displacement during the Holocene Epoch (considered present time and defined for purposes of the act as approximately the last 11,000 years). A fault is considered well defined if its trace can be clearly identified by a trained geologist at the ground surface or in the shallow subsurface using standard professional techniques, criteria, and judgment. (Hart and Bryant 1997.)

Seismic Hazards Mapping Act

Like the Alquist-Priolo Act, the Seismic Hazards Mapping Act of 1990 (PRC 2690–2699.6) is intended to reduce damage resulting from earthquakes. While the Alquist-Priolo Act addresses surface fault rupture, the Seismic Hazards Mapping Act addresses other earthquake-related hazards, including strong ground shaking, liquefaction, and seismically induced landslides. Its provisions are similar in concept to those of the Alquist-Priolo Act: the state is charged with identifying and mapping areas at risk of strong ground shaking, liquefaction, landslides, and other corollary hazards, and cities and counties are required to regulate development within mapped seismic hazard zones.

Under the Seismic Hazards Mapping Act, permit review is the primary mechanism for local regulation of development. Specifically, cities and counties are prohibited from issuing development permits for sites within seismic hazard zones until appropriate site-specific geologic and geotechnical investigations have been carried out and measures to reduce potential damage incorporated into the development plans.

California Building Standards Code

The State of California's minimum standards for structural design and construction are given in the California Building Standards Code (CBSC) (24 CCR). The CBSC is based on the Uniform Building Code (UBC) (International Code Council 1997), which is used widely throughout the United States (generally adopted on a state-by-state or district-by-district basis). For the CBSC, the UBC has been modified for California conditions with numerous, more detailed or more stringent regulations. The CBSC requires that "classification of the soil at each building site shall be determined when required by the building official" and that "the classification shall be based on observation and any necessary test of the materials disclosed by borings or excavations."

In addition, the CBSC states that "the soil classification and design-bearing capacity shall be shown on the [building] plans, unless the foundation conforms to specified requirements." The CBSC provides standards for various aspects of construction, including excavation, grading, and earthwork construction; fills and embankments; expansive soils; foundation investigations; and liquefaction potential and soil strength loss. In accordance with California law, certain aspects of the program would be required to comply with all provisions of the CBSC.

California Surface Mining and Reclamation Act

The Surface Mining and Reclamation Act of 1975 (SMARA) (PRC Sections 2710–2719) is the principal legislation addressing mineral resources in California. SMARA was enacted in response to land use conflicts between urban growth and essential mineral production. Its stated purpose is to provide a comprehensive surface mining and reclamation policy that will encourage the production and conservation of mineral resources while ensuring that:

- significant environmental effects of mining are prevented or minimized;
- mined lands are reclaimed and residual hazards to public health and safety are eliminated; and
- consideration is given to recreation, watershed, wildlife, aesthetic, and other related values.

SMARA governs the use and conservation of a wide variety of mineral resources, although some resources and activities are exempt from its provisions, including excavation and grading conducted for farming, construction, or recovery from flooding or other natural disaster.

SMARA provides for the evaluation of an area's mineral resources using a system of mineral resource zone (MRZ) classifications that reflect the known or inferred presence and significance of a given mineral resource. The MRZ classifications are based on available geologic information, including geologic mapping and other information on surface exposures, drilling records, and mine data; and socioeconomic factors such as market conditions and urban development patterns. The MRZ classifications are defined as follows.

- **MRZ-1**: Areas where adequate information indicates that no significant mineral deposits are present, or where it is judged that little likelihood exists for their presence.
- **MRZ-2:** Areas where adequate information indicates that significant mineral deposits are present, or where it is judged that a high likelihood for their presence exists.
- **MRZ-3:** Areas containing mineral deposits, the significance of which cannot be evaluated from available data.
- **MRZ-4:** Areas where available information is inadequate for assignment into any other MRZ.

The State of California is responsible for mineral resources zoning under SMARA, but SMARA implementation and enforcement authority rests with the local jurisdiction and is carried out through the county or city land use planning process and codes. Yolo County's SMARA implementing regulations are contained in Chapter 3 of Title 10 of the County Code. Solano County's SMARA implementing regulations are contained in Chapter 29 of the County Code.

3.4.2.1.2 Local

Yolo County

The Health and Safety Element of the *Draft 2030 Countywide General Plan* for Yolo County (Yolo County 2008) contains goals, policies, and actions aimed at reducing the risk of geologic or seismic hazards in the county. Any violation of these goals, policies, and actions would constitute a significant effect.

Goals

Goal HS-1 Geologic and Seismic Hazards: Protect the public and reduce damage to property from earthquakes and other geologic hazards.

Policies

Policy HS-1.1: Regulate land development to avoid unreasonable exposure to geologic hazards.

Policy HS-1.2: All development and construction proposals shall be reviewed by the County to ensure conformance to applicable building standards.

Policy HS-1.3: Require environmental documents prepared in connection with CEQA to address seismic safety issues and to provide adequate mitigation for existing and potential hazards identified.

Actions

Action HS-A1: Require a geotechnical analysis for construction in areas with potential geological hazards and/or for purposes of environmental analysis. Recommendations of the geotechnical analysis shall be implemented.

Action HS-A2: Rely upon the most current and comprehensive geological hazard mapping available in the evaluation of potential seismic hazards associated with proposed new development.

Action HS-A3: Continue to participate in the Yolo County Subsidence Network and implement its recommendations.

Solano County

The Public Health and Safety Chapter of the *Solano County General Plan* (Solano County 2008) contains goals, policies, and implementation programs aimed at reducing the risk of geologic or seismic hazards within the county. Any violation of these goals, policies, and implementation programs would constitute a significant effect.

Policies

HS.P-12: Require new development proposals in moderate or high seismic hazard areas to consider risks caused by seismic activity and to include project features that minimize these risks.

HS.P-13: Review and limit the location and intensity of development and placement of infrastructure in identified earthquake fault zones.

HS.P-14: Identify and minimize potential hazards to life and property caused by fault displacement and its effect on facilities that attract large numbers of people, are open to the general public, or provide essential community services and that are located within identified earthquake fault zones.

HS.P-15: Reduce risk of failure and reduce potential effects of failure during seismic events through standards for the construction and placement of utilities, pipelines, or other public facilities located on or crossing active fault zones.

HS.P-16: Require minimum setbacks for construction along creeks between the creek bank and structure, except for farm structures that are not dwellings or places of work, based on the susceptibility of the bank to lurching caused by seismic shaking.

HS.P-17: Restrict the crossing of ground failure areas by new public and private transmission facilities, including power and water distribution lines, sewer lines, and gas and oil transmission lines.

HS.P-18: Make information about soils with a high shrink-swell potential readily available. Require proper foundation designs in these areas.

HS.P-19: Minimize development in areas with high landslide susceptibility.

Regulations

HS.I-18: Revise the County Zoning Ordinance to do the following:

- Limit development occurring in geologic hazard areas, including active fault traces and fault zones, landslide susceptibility zones, and creek banks susceptible to lurching.
- Prohibit structures in active fault trace areas. Per the Alquist-Priolo Earthquake Fault Zoning Act, structures for human occupancy must be set back at least 50 feet from active fault traces.
- Further limit development intended for human occupancy within 100 feet of active fault trace areas to one-story wood-frame structures.

HS.I-19: Adopt and enforce the most current versions of the International Building Codes, as modified by the California Building Standards Commission.

HS.I-20: Create or modify design requirements for new utilities which will guide the construction and placement of these utilities.

HS.I-21: Require geotechnical investigation and recommendations for buildings meant for public occupancy within geologic hazard areas. A state certified

Engineering Geologist shall produce a report examining development issues that considers:

- soil, slope, or other geologic hazard conditions found on site;
- potential off-site development effects, such as increased runoff and/or slope instability; and
- requirements of any regulations concerning the hazard area.

HS.I-22: Require geotechnical evaluation and recommendations before new development in moderate or higher-hazard areas. Such geotechnical evaluation shall analyze the potential hazards from:

- landslides
- liquefaction
- expansive soils
- steep slopes
- erosion
- subsidence
- Alquist-Priolo Earthquake Fault Zones or other identified fault zones
- tsunamis
- seiches

Require new development to incorporate project features that avoid or minimize the identified hazards. Costs related to providing or confirming required geotechnical reports will be borne by the applicant.

HS.I-23: Require owners of all existing or proposed oil, gas, water, and sewer pipelines that cross active faults to file an operations plan describing the probable effects of pipeline failure at the fault and the various emergency facilities and procedures that exist to ensure that failure does not threaten public safety.

HS.I-24: Provide current data to the public regarding geologic hazards. Coordinate with cities to gather and periodically assess new geologic data including fault zone activity, landslide activity, and distribution of shrink-swell soils.

HS.I-25: Develop a geologic constraints and hazards database to be maintained in the County geographic information system (GIS). The GIS shall be used to identify areas containing hazards and constraints that could potentially affect the type or level of development allowed in these areas. Make these data available to the public. Information maintained as part of the database may include:

- active faults

- relative seismic shaking hazards
- relative landslide susceptibility
- relative earthquake induced liquefaction susceptibility
- steep-slope constraints
- moderate and high-erosion hazards
- soils with high clay content indicating shrink swell potential
- agricultural soils and/or bay mud subject to high water levels
- extreme, very high, and high wildfire risk using the Wildland Fire Hazard Areas map provided by the California Department of Forestry and Fire Protection

City of West Sacramento General Plan

In 1990, the City of West Sacramento adopted the *City of West Sacramento General Plan*. The plan was last revised and adopted on December 8, 2004. The *City of West Sacramento General Plan* outlines goals and policies related to natural resources within the study area. The following objectives, policies, and implementation procedures are relevant to the study area.

Health and Safety

Goal A: To prevent loss of life, injury, and property damage due to geologic and seismic hazards.

Policy

1. The City shall require preparation of geotechnical reports and impose appropriate mitigation measures to ensure, within the limits of technical and economic feasibility, that new structures are able to withstand the effects of seismic activity, including liquefaction.
2. Underground utilities, particularly water and natural gas mains, shall be designed to withstand seismic forces.
3. The City shall require post-earthquake building replacement, reconstruction, and rehabilitation to conform to the latest City code requirements.

Grading and Erosion Control Ordinances

Many counties and cities have grading and erosion control ordinances. These ordinances are intended to control erosion and sedimentation caused by construction activities. A grading permit typically is required for construction-related projects in West Sacramento. As part of the permit, the project applicant usually must submit a grading and erosion control plan, project vicinity and site maps, and other supplemental information. Standard conditions in the grading permit include an extensive list of BMPs similar to those contained in an SWPPP.

The City's relevant regulations can be found in the Municipal Code, Title 15 (City of West Sacramento 2004b). Chapter 15.08 establishes standards and procedures for grading and excavation to minimize hazards to life and limb; protect against erosion; maintain the natural environment; and protect the safety, use, and stability of public rights-of-way and drainage channels. It ensures that projects approved under this chapter will be free from harmful effects of runoff, including inundation and erosion, and that neighboring and downstream properties will be protected from

drainage problems resulting from new developments. It also ensures proper restoration of vegetation and soil systems disturbed by grading or fill activities authorized under this chapter. It is intended through this chapter to maintain an attractive and healthy landscape and to control against dust and erosion and their consequent effects on soil structure and water quality.

Solano County has adopted the 1997 UBC and 2001 CBSC, including the optional appendices that regulate earthwork. The County's grading codes (also referred to as the Grading, Drainage, Land Leveling and Erosion Control Ordinance) are contained in Chapter 31 of the County Code. The County requires grading permits for most earthwork, with the exception of the following actions.

- Small excavations and fills (those with no more than 8,000 square feet disturbed, an excavated volume less than 150 cubic yards, a finished depth less than 4 feet, and slopes no steeper than 2:1).
- Landscaping of areas smaller than 10,000 square feet.
- Excavation for structures—such as pools, basements, and septic tanks—that typically are covered through other permit processes.
- Permitted land leveling for agricultural purposes.
- Agricultural activities on previously graded or leveled lands.
- Utility trenches, wells, and exploratory excavations by licensed personnel.
- Activities in disposal areas, landfills, quarries, stockpiles, and other operations where a County Use Permit has been granted.
- Grading for fire roads and firebreaks.
- Grading by Solano County or Special Districts; grading for projects on state- or federally owned or operated lands.

Mineral and Energy Resources

The Resources Element of the *Solano County General Plan* (Solano County 2008) recognizes the economic importance of the county's mineral resources and contains policies (Policy RS.P-32) to ensure the following:

- areas with important mineral resources are zoned and developed in ways that maintain resource availability;
- mineral extraction activities are performed in a manner that is compatible with surrounding land uses;
- significant environmental effects of extractive activities are avoided; and
- mined sites are properly restored following closure, consistent with SMARA requirements and surrounding land uses.

General plan policies regarding natural gas resources differ somewhat from those for non-fuel mineral resources. The general plan recognizes the past and current importance of natural gas in Solano County but also stresses that natural gas has a limited lifespan as an alternative to other fossil fuels. General Plan Policy RS.P-54 identifies the importance of "responsible extraction, storage, and transportation of natural gas resources" to "minimize the effect on the natural environment." (Solano County 2008.)

3.4.2.2 Environmental Setting

This section discusses the existing conditions related to geology, seismicity, soils, and mineral resources in the study area.

3.4.2.2.1 Study Area

Regional Physiographic Setting of the Study Area

The study area is located in the southern portion of the Sacramento Valley within the northern portion of California's Great Valley Geomorphic Province. The Great Valley is a narrow, elongated topographic depression that is approximately 450 miles long and 40 to 70 miles wide. The basin is bordered by the Sierra Nevada plutonic complex to the east and the California Coast Ranges to the west, and the Klamath and Cascade Mountains to the north. The Sacramento Valley contains thousands of feet of accumulated fluvial, overbank, and fan deposits resulting from erosion of these surrounding ranges. The sediments vary from a thin veneer at the edges of the valley to 50,000 feet in the west-central portion and are estimated to be about 8,000 feet thick in the study area. (Northwest Hydraulic Consultants 2007.)

The Sacramento River is the main drainage of the region flowing generally south from the Klamath Mountains to its discharge point into the Suisun Bay in the San Francisco Bay Area. In the Sacramento area the Sacramento and American Rivers have been confined by human-made levees since the turn of the 19th century. In the study area, these levees generally were constructed on Holocene age (less than 11,000 years old) alluvial and fluvial deposits deposited by the current and historic Sacramento River and its tributaries. (Kleinfelder 2007.)

Regional Geology and Topography

The surface and subsurface distributions of sandy and clayey deposits are a function of former river positions on the landscape, present-day geomorphic processes adjacent to the river positions on the landscape, and present-day geomorphic processes adjacent to the river channel (i.e., flooding and deposition) (William Lettis & Associates 2007). Helley and Harwood (1985) compiled previous regional studies of the quaternary geology of the Sacramento Valley. Previous geologic mapping in the West Sacramento study area generalized the surficial deposits as Quaternary alluvium (Qa) proximal to the modern river channel and undifferentiated Quaternary basin (Qb) deposits away from the modern river channel. Helley and Harwood (1985) differentiate basin deposits from alluvium on the basis of composition, including only those deposits that are finer-grained and frequently organic-rich, and suggests these deposits were distal deposits where energy conditions were much lower. Both of these map units are considered Holocene age.

Mapping by Helley and Harwood(1985) indicates the entire Sacramento River South Levee is underlain by alluvium and basin deposits. Mapping by Helley and Harwood (1985) also indicates the entire DWSC East and West Levees and Port North and South Levees are underlain by basin deposits with the exception of the Port North Levee Stations 242+00 to 263+57.24 and Port South Levee Stations 1045+00 to 1134+00, which are underlain by peat deposits (Qp) and Stations 996+00 to 1000+00 and 1038+00 to 1045+00 which are underlain by stream channel deposits (Qsc). Peat deposits are decomposing organic deposits with minor inclusions of clay and silt. Stream channel deposits are recent and historic. Alluvial deposits within the active river channel, generally

consisting of unconsolidated sand, gravel, and silt. Other quaternary sediments exposed near West Sacramento in smaller inclusions are described as (Kleinfelder 2007):

- undivided older alluvium deposits (Qal): undivided gravel, sand, and silt deposited during the Holocene and Pleistocene;
- Modesto formation (upper and lower member) (Qmu and Qml): unconsolidated, unweathered to slightly weathered gravel, sand, silt, and clay (the stream channel, alluvial, basin, and peat deposits lie conformably above this unit); and
- Riverbank formation (upper and lower member) (Qru and Qrl): unconsolidated but compact to semi-consolidated, dark brown to red gravel, sand, and silt with some clay.

The Qru/Qrl and the Qmu/Qml deposits represent ancestral river channels and alluvial fans. These semi-consolidated to unconsolidated deposits are characterized by localized paleochannels and lateral and vertical stratigraphic complexity related to past fluvial processes and buried paleo-topography. These formations are mantled by unconsolidated deposits of Holocene age that comprise most of the surficial geologic deposits within the West Sacramento area. Deposits laid down by the Sacramento River between the mid- to late 1800s probably were derived from hydraulic mining debris. (William Lettis & Associates 2007.)

3.4.2.2.2 Soils

Soil map units of the study area as described by the *Soil Survey of Yolo County* (Andrews 1972) and Soil *Survey of Solano County* (Bates1977) are shown on Figure 3.4-1 and characterized in Table 3.4-1. Soil characteristics shown on the table can be summarized as follows.

- Soils that dominate the study area generally have a sandy surface layer and as such have rapid permeability. Erodibility is low in areas that exhibit flat topography, such as the landside of the levee. The hazard of erosion on the steeper levee banks is greater. Additionally, erosion hazard on the waterside of the levee varies with the frequency of high water events within the Sacramento River, Sacramento and Yolo Bypass, and the DWSC.
- The subsurface (generally deeper than 40 inches) soils present a moderate to high shrink-swell potential (expansion and contraction cycle when wetted and dried).
- Because of the sandy surface layer, natural fertility of nearly all of the study area soils is relatively low; therefore, topsoil may need to be amended after disturbance to reestablish plant cover. Revegetation should be aided by the relatively moderate depth to the water table, which is deep enough to allow good aeration of plant roots but shallow enough to allow roots to have access to groundwater.

Table 3.4-1. Soils in the Study Area

Soil Series Name	Reach	Depth (inches)	USDA Texture	Color	Shrink-Swell Potential	Hydrologic Group	Erosion Hazard	Runoff
Lang sandy loam (La)	Sacramento River West North Levee 2, 7, 8 Port North Levee 9A	0–13	Sandy loam and loamy fine sand	Pale brown	Low	B, drained; C, undrained	None to slight	Very slow
		13–19	Loamy fine sand	Mottled light brownish-gray to brownish-yellow				
		19–60	Stratified fine sand, loamy fine sand, and silt loam	Mottled light gray, gray, reddish-yellow, and light brownish-gray				
Lang sandy loam, deep (Lb)	Sacramento Bypass 6 Yolo Bypass 5 Sacramento River South Levee 1	0–13	Sandy loam and loamy fine sand	Pale brown	Low at 0 to 40 inches, High at 40 to 60 inches	B, drained; C, undrained	None to slight	Very slow
		13–19	Loamy fine sand	Mottled light brownish-gray to brownish-yellow				
		19–40	Fine sand to loamy fine sand	Light brownish gray				
		40–60	Clay to heavy clay	Pale brown				
Lang silt loam (Ld)	Sacramento River South Levee 1	0–10	Sandy loam and loamy fine sand	Pale brown	Low at 0 to 40 inches, High at 40 to 60 inches	B, drained; C, undrained	None to slight	Very slow
		10–16	Silt loam	Mottled light brownish-gray to brownish-yellow				
		16–40	Fine sand to loamy fine sand	Light brownish gray				
		40–60	Clay to heavy silty clay loam	Pale brown				
Riz loam, flooded (Rn)	Yolo Bypass 5	0–10	Loam	Light brownish-gray	Moderate to High	D	None to slight	Very slow
		10–37	Heavy clay loam and clay	Mottled, light brownish-gray, brown and yellowish brown				
		37–69	Clay loam and loam	Mottled, light yellowish-brown				

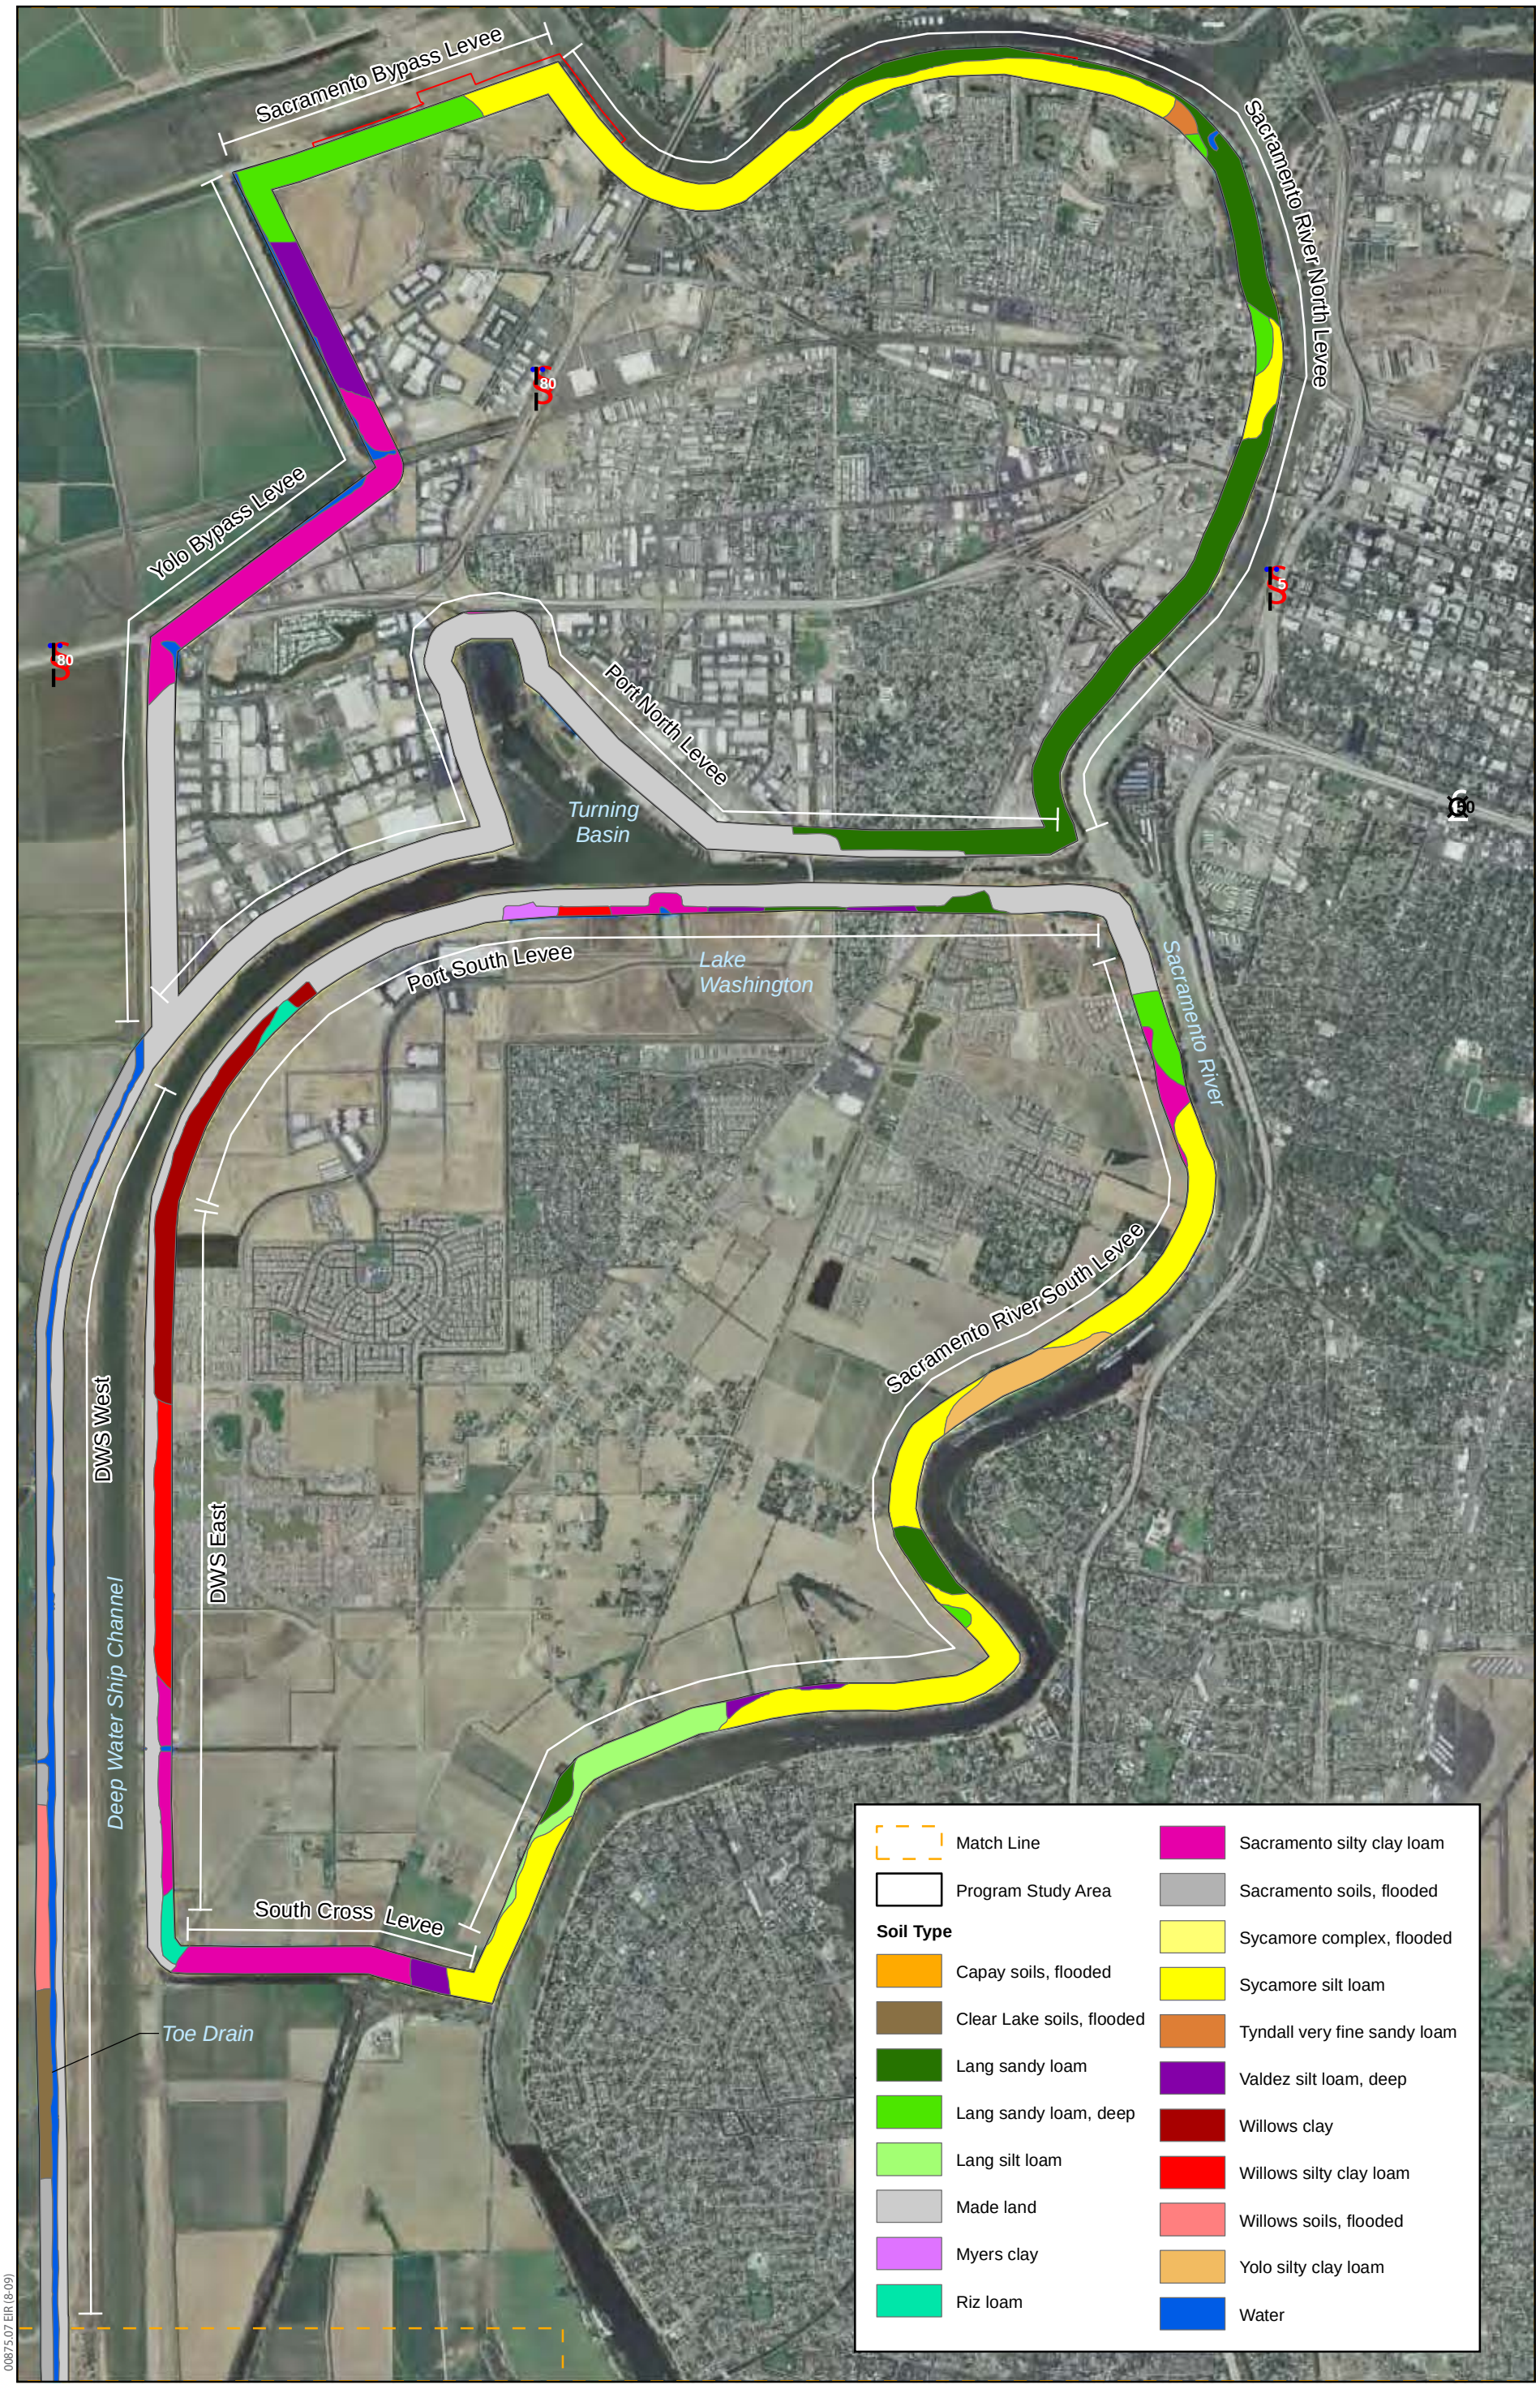

Figure 3.4-1
Soil Types within the Study Area

Figure 3.4-1
Soil Types within the Study Area

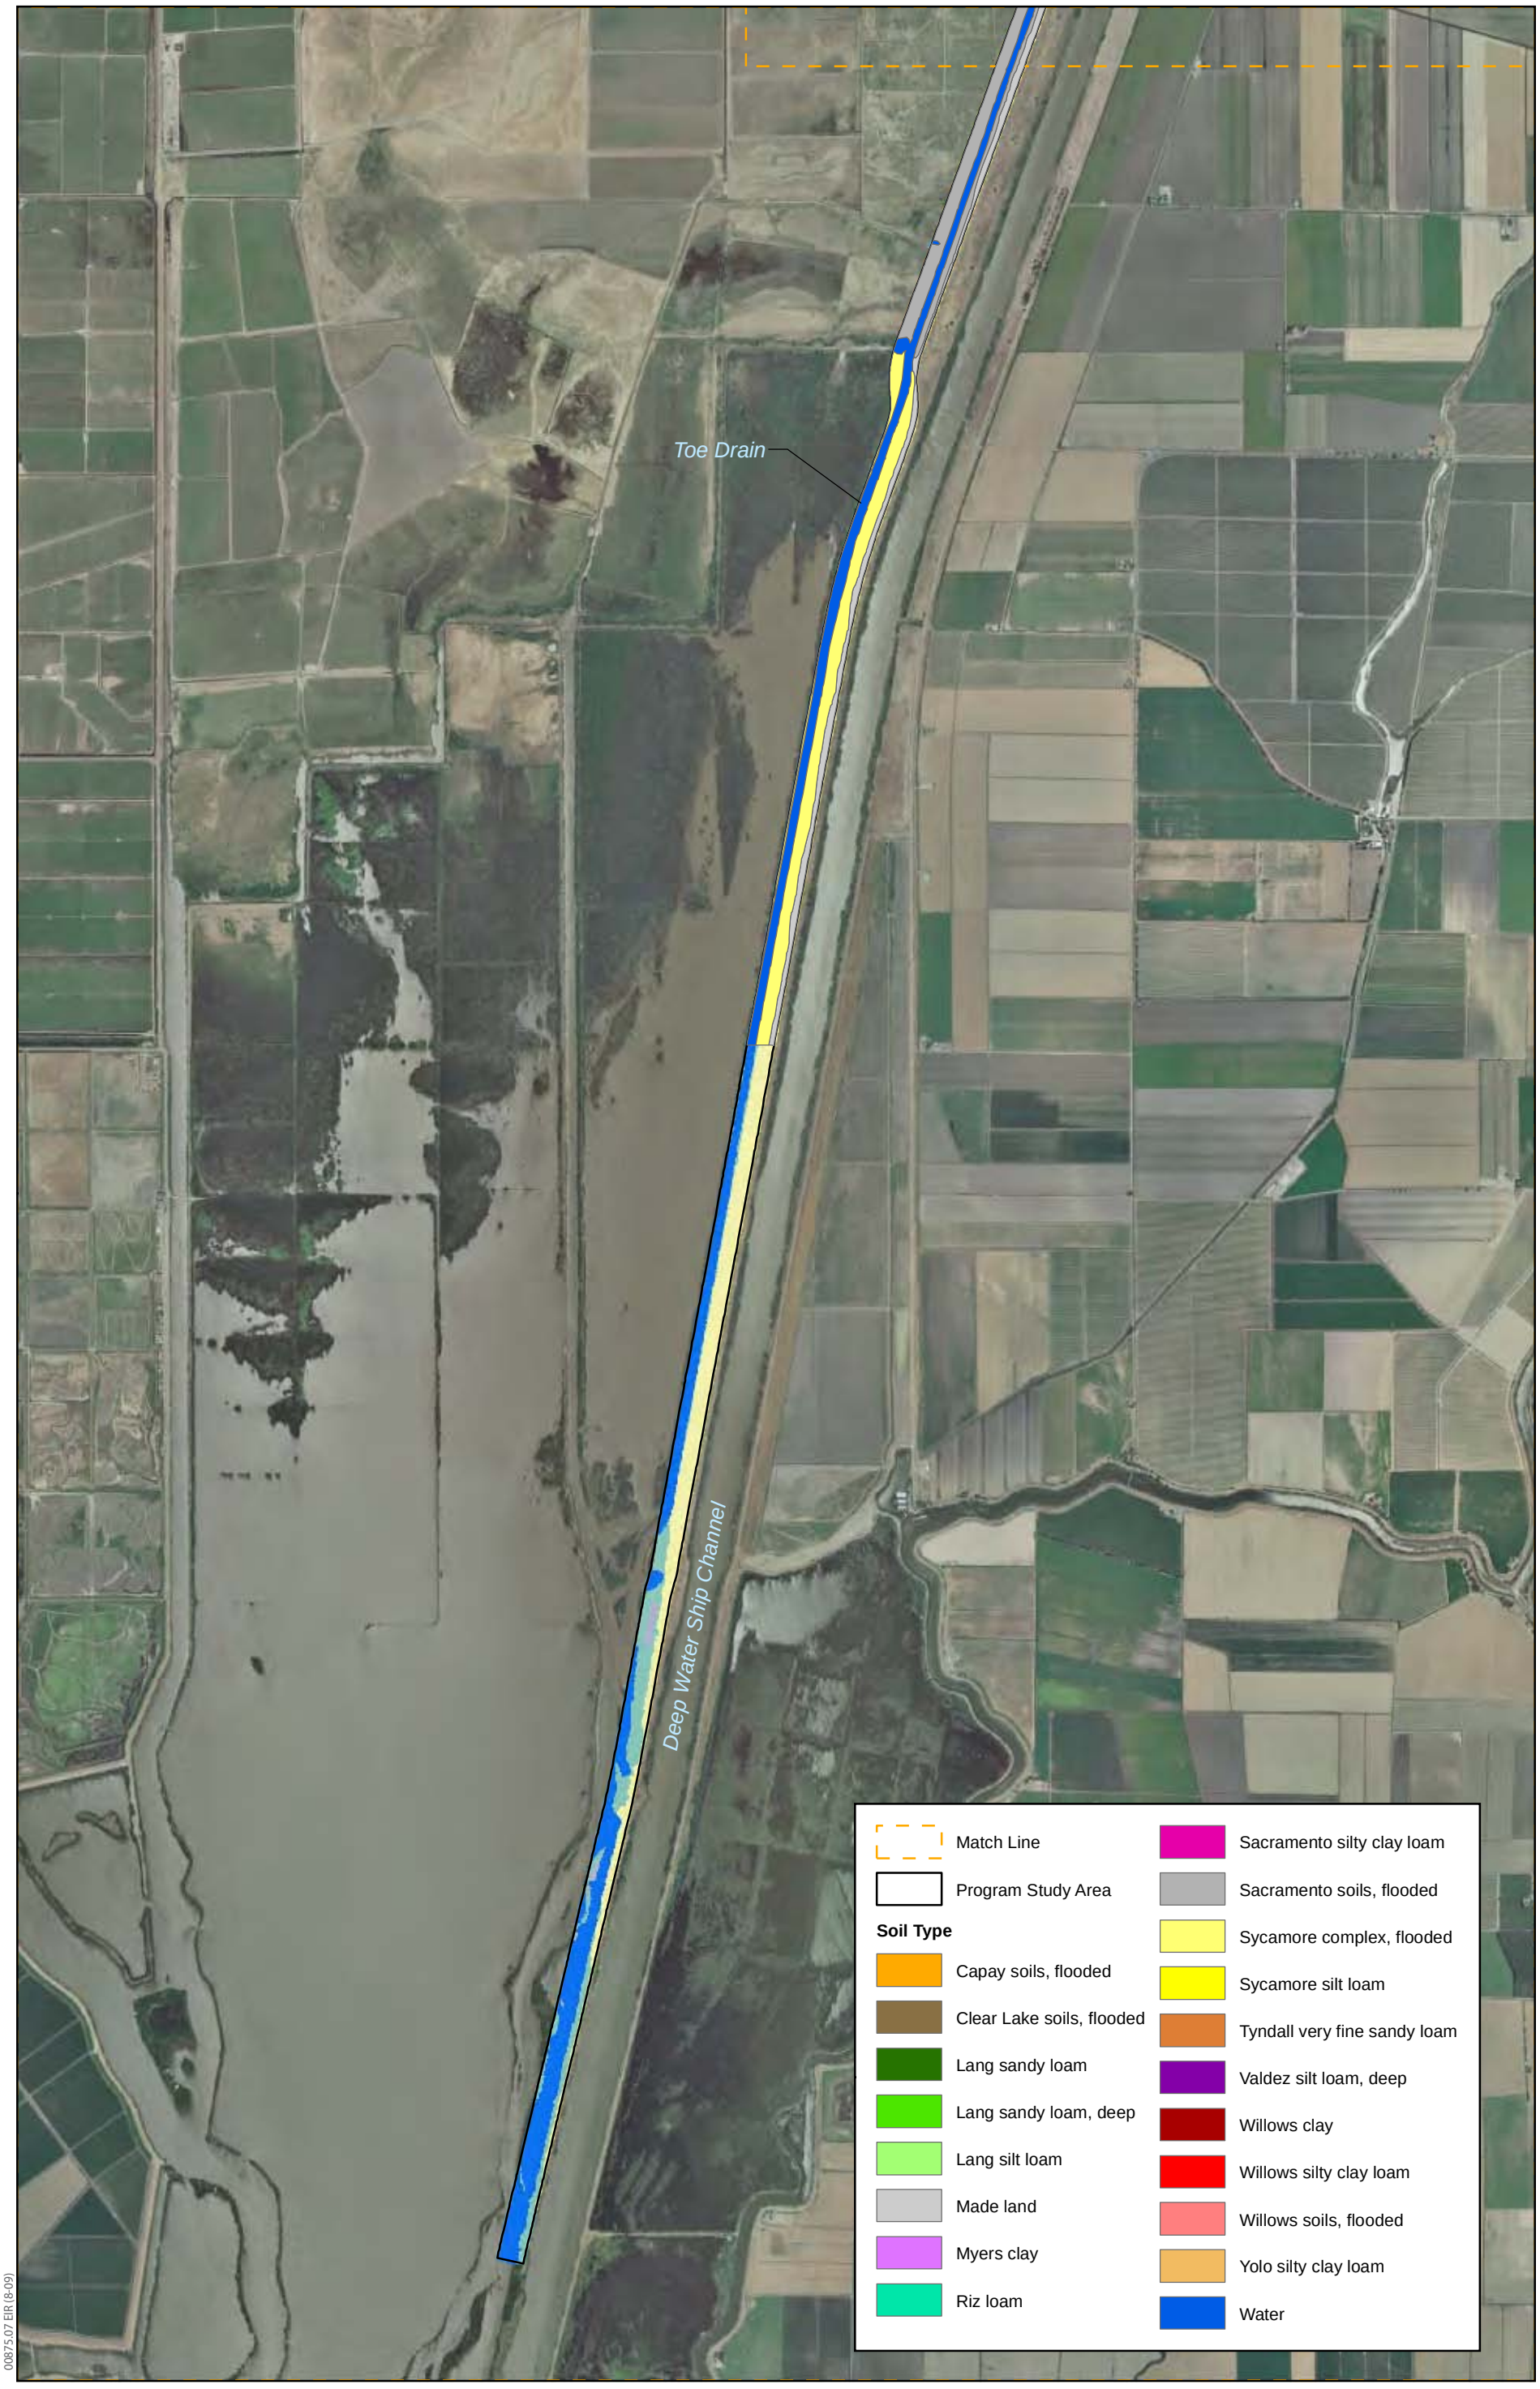

Figure 3.4-1
Soil Types within the Study Area

Soil Series Name	Reach	Depth (inches)	USDA Texture	Color	Shrink-Swell Potential	Hydrologic Group	Erosion Hazard	Runoff
Sacramento silty clay loam (Sa)	Yolo Bypass 5 Port North Levee 9A Sacramento River South Levee 1 South Cross Levee 3	0–20	Silty clay loam	Mottled gray	High	C	None to slight	Very slow
		20–60	Clay	Mottled gray				
Sacramento soils, flooded (Sg)	Yolo Bypass 5	0–8	Silty clay loam	Mottled gray	High	D	None to slight	Very slow
		8–20	Sandy loam to silty clay	Mottled gray				
		20–60	Clay	Mottled gray				
Sycamore silt loam (So)	Sacramento Bypass 6 Sacramento River South Levee 1 South Cross Levee 3	0–14	Silty clay loam or silt loam	Grayish brown	High	C	None to slight	Very slow
		14–30	Silty clay loam	Mottled light yellowish-brown				
		30–60	Loam	Pale olive				
Valdez silt loam, deep (Vb)	Yolo Bypass 5	0–14	Silt loam	Pale brown	High	C	None to slight	Very slow
		14–21	Very fine sandy loam	Light gray				
		21–65	Silt loam	Pale brown and light yellowish-brown				
Made land (Ma)	Made land is a miscellaneous land type that consists of randomly mixed material redeposited by the construction of the Sacramento-Yolo DWSC, turning basin, and navigational locks. There are also a few small areas in which deeps fills have been made in old sloughs. The profile is a stratified, heterogeneous mixture of soil that ranges in texture from sand to clay and in some places consists of uniform texture that ranges from sand to clay and has some gravelly areas. Depth ranges from 5 to 10 feet near the DWSC and up to 15 feet in the vicinity of the turning basin. The surface runoff is very slow, and the erosion hazard is none to slight.							

Sources: Andrews 1972; Bates 1977.

3.4.2.2.3 Mineral Resources

No commercial mining operations are known to have occurred in West Sacramento. Most of the area is classified as MRZ-1 by the California Division of Mines and Geology, which indicates no significant mineral deposits are present. The portion of the West Sacramento area that borders the Sacramento

River (and henceforth the study area vicinity) is classified as MRZ-3, which means aggregate deposits of undetermined significance occur there. Lands classified as MRZ-1 or MRZ-3 are not affected by state policies pertaining to the maintenance of access to regionally significant mineral deposits under the California Surface Mining and Reclamation Act of 1975. However, as indicated in the geotechnical report for the proposed program (Kleinfelder 2007), the study area contains scattered pockets of sand (sand and aggregate being the mineable mineral resources typically found in the program region), in layers and at various depths; therefore, the study area could not be effectively or economically mined and is considered not to contain regionally or locally important mineral resources.

3.4.2.2.4 Seismic Hazards

Seismic hazards refer to earthquake fault ground rupture and ground shaking (primary hazards), as well as liquefaction and earthquake-induced slope failure (secondary hazards). Localized ground shaking and liquefaction are the most significant seismic hazards in Yolo County (Yolo County 1983).

Primary Seismic Hazards—Surface Fault Rupture[1] and Groundshaking

The study area is located in a region of California characterized by low seismic activity. The UBC recognizes no active seismic sources in the program vicinity (International Conference of Building Officials 1997), and no active faults are known to cross the study area. The study area is located within UBC Seismic Hazard Zone 3. The Zone 3 designation indicates that earthquakes in the region have the potential to make standing difficult and to cause stucco and some masonry walls to fall. Structures must be designed to meet the regulations and standards associated with Zone 3 hazards.

Three pre-Quaternary faults/fault zones are located within an approximately 20-mile radius of the study area. The Willows fault zone runs northwest to southeast of the study area; the East Valley fault runs to the west of the study area; and the Midland fault zone runs to the southeast of the study area (City of West Sacramento Department of Community Development 1990; Jennings 1994). None of these faults/fault zones are within an Alquist-Priolo Special Studies Zone (Hart and Bryant 1997). The active fault nearest to the study area is the Dunnigan Hills fault, which is 30 miles to the northwest (City of West Sacramento Department of Community Development 1990; Jennings 1994). This fault is within an Alquist-Priolo Special Studies Zone (Hart and Bryant 1997). The critical earthquake for West Sacramento would originate at the nearest point of the Midland fault zone or the Dunnigan Hills fault (City of West Sacramento Department of Community Development 1990).

Based on a probabilistic seismic hazard map that depicts the peak horizontal ground acceleration values exceeded at a 10% probability in 50 years (California Geological Survey 2003; Cao et al. 2003), the probabilistic peak horizontal ground acceleration values for the study area are 0.1 to 0.2g (where g equals the acceleration speed of gravity). As a point of comparison, probabilistic peak horizontal ground acceleration values for the San Francisco Bay Area range from 0.4g to more than 0.8g. This indicates that the ground-shaking hazard in the study area is low. Farther to the west, the ground shaking hazard increases, coinciding with the increase in abundance of associated faults and fault complexes (California Geological Survey 2003; Cao et al. 2003).

[1] *Surface fault rupture* is a rupture at the ground surface along an active fault, caused by earthquake or creep activity.

Additionally, URS evaluated northern reaches of the basin for seismic vulnerability and liquefaction of the levees in the report *Phase 1 Geotechnical Evaluation Report (P1GER) West Sacramento Region,* dated September 2007.

Preliminary seismic evaluations have been completed in the form of two reports; *West Sacramento Levee System Problem Identification and Alternative*

Analysis: Volume 1—Geotechnical Problem Identification Solano and Yolo Counties, California completed by Kleinfelder (September 2007) and *Phase 1 Geotechnical Evaluation Report (P1GER) West Sacramento Region* completed by URS (November 2007) for DWR. Data collection included 323 borings drilled with SPTs and soundings made using CPTs along the levees within the basin. Approximate stationing endpoints have been determined by URS and Kleinfelder based on similar soil characteristics within the endpoints (HDR, Inc. 2008).

Liquefaction

Poorly consolidated, water-saturated fine sands located within 30 to 50 feet of the surface typically are considered the most susceptible to liquefaction. Soils and sediments that are not water-saturated and that consist of coarser or finer materials are generally less susceptible to liquefaction (California Division of Mines and Geology 1997).

URS performed a liquefaction-triggering analysis to evaluate whether any levee or underlying foundation materials potentially would liquefy during the considered earthquake events. Criteria for susceptibility to liquefaction included soil type, liquid limit, plasticity index, water content, and fines content. If the material was considered to be susceptible to liquefaction, steps were completed to further evaluate the liquefaction potential of the material considering the earthquake loading. In contrast, if the plasticity of the material was high enough to preclude liquefaction, the material was classified as non-liquefiable, irrespective of the earthquake loading. (URS 2007.)

Four of the nine levee reaches in the study area may exhibit liquefaction during a seismic event. These levee reaches are Sacramento River North, Sacramento Bypass, Yolo Bypass, and Sacramento River South. (HDR, Inc. 2008.)

3.4.3 Environmental Consequences

This section describes the geology and soils effects associated with the program. It describes the methods used to determine the effects of the program and lists the thresholds used to conclude whether an effect would be significant. Measures to mitigate (i.e., avoid, minimize, reduce, eliminate, or compensate for) significant effects accompany each effect discussion.

3.4.3.1 Assessment Methods

Evaluation of the geology, seismicity, and soils effects in this section is based on the information provided by technical maps, reports, and other documents that describe the geologic, seismic, and soil conditions of the study area. This information was then compared to the type and location of proposed flood and recreation alternatives to determine whether effects would occur.

3.4.3.2 Determination of Effects

Criteria for determining the significance of effects related to geology, soils, and mineral resources were developed based on the environmental checklist form in Appendix G of the State CEQA Guidelines (14 CCR 15000 *et seq.*). An effect related to geology, soils, and seismicity was considered significant if it would:

- expose people or structures to potential substantial adverse effects, including the risk of loss, injury, or death involving:
- rupture of a known earthquake fault, as delineated on the most recent Alquist-Priolo Earthquake Fault Zoning Map issued by the state geologist for the area or based on other substantial evidence of a known fault (refer to Division of Mines and Geology Special Publication 42);
- strong seismic ground shaking;
- seismic-related ground failure, including liquefaction; or
- landslides;
- result in substantial soil erosion or the loss of topsoil;
- be located on a geologic unit or soil that is unstable or that would become unstable as a result of the project and potentially result in an on-site or off-site landslide, lateral spreading, subsidence, liquefaction, or collapse;
- be located on expansive soil, as defined in Table 18-1-B of the UBC (International Code Council 1997), creating substantial risks to life or property;
- have soils incapable of adequately supporting the use of septic tanks or alternative wastewater disposal systems in areas where sewers are not available for the disposal of wastewater;
- result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the state; or
- result in the loss of availability of a locally important mineral resource recovery site delineated on a local general plan, specific plan, or other land use plan.

3.4.3.2.1 Effect Assumptions

The following assumptions were made regarding program effects on geology, seismicity and soils in the study area.

- Fill or borrow material will be obtained from a quarry or other authorized (i.e., permitted) location.
- WSAFCA would conform to the latest CBSC standards, city and county standards, and NPDES requirements.
- There are no active faults, potentially active faults, or Alquist-Priolo Earthquake Fault Zones located in or adjacent to the study area.

3.4.3.3 Effects and Mitigation Measures

3.4.3.3.1 No Action Alternative

To recap from Chapter 2, Alternatives, the No Action Alternative is the continuation of the existing deficiencies along the nine levee reaches and absence of levee alternatives to increase the level of protection. Current levee operations and maintenance activities would continue. No construction-related effects involving direct ground-disturbing activities or changes to flood control facilities that could result in changes in geology, seismicity, soils, or mineral resources would occur. Therefore, there would be no construction-related effects on these resources attributable to implementation of the No Action Alternative.

Without levee alternatives, there is the continued risk of levee failure and continuing underseepage and loss of levee foundation soil would be expected to continue. If a levee overtopping or breach were to occur, floodwaters would likely erode topsoil which could either be pumped back into the Sacramento River, DWSC, or the Yolo or Sacramento Bypasses, or recede back through the levee breach. A catastrophic levee failure could result in the collapse of miles of levee slopes, alteration of regional and local hydrology and a substantial increase in erosion and sedimentation. This condition would cause severe damage to local soils, areas of scour holes, and eroded and unstable landforms. Moreover, subsequent flooding could occur prior to levee repair that would resulting in additional erosion and loss of topsoil. It is assumed that these effects would be significant; however, given the uncertainty of the occurrence or magnitude of such an event, the effects cannot be quantified based on available information.

Furthermore, the beneficial effects attributable to program implementation such as improved levee stability and decrease of levee bank erosion would not be realized under the No Action Alternative.

3.4.3.3.2 Flood and Recreation Program Alternatives

Effect GEO-1: Effects on Levee Stability

The proposed program would improve the stability of the levees in all nine reaches by further reducing seepage and the potential for seepage-related failures by reducing hydrostatic exit gradients, creating more stable slopes and reducing erosion. Therefore, this effect would be beneficial.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Levee raise (in place)	▪ Sheet pile wall
	▪ Levee raise (adjacent)	▪ Slurry cutoff wall
	▪ Levee raise (full)	▪ Slope flattening
	▪ Interior drain	▪ Stability berm
	▪ Jet grouting	▪ Rock slope protection
	▪ Relief wells	▪ Setback levee
	▪ Seepage berm	▪ Vegetation removal

Affected Reaches

Although different flood program alternatives are proposed for the reaches, this effect would occur in all nine program reaches.

Effect GEO-1 Finding	With Mitigation
Beneficial	N/A

Effect GEO-2: Effects on Levee Bank Erosion

Evidence of localized, accelerated erosion caused by wave action and channel flows was identified within the study area. Installation of rock slope protection as proposed would substantially reduce bank erosion rates and improve overall levee stability. Therefore the proposed program would have a beneficial effect on levee bank erosion potential.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative
Flood	▪ Rock slope protection ▪ Vegetation removal

Affected Reaches

Erosion control measures are proposed in the Sacramento South and North Levee reaches, the Port North and Port South Levee reaches, and the DWSC East and West Levee reaches.

Effect GEO-2 Finding	With Mitigation
Beneficial	N/A

Effect GEO-3: Effects Resulting from Seismic Groundshaking and Liquefaction

Based on available knowledge of fault location and locations of earthquake epicenters, the risk of groundshaking in the study area is low. Nonetheless, a large earthquake on a nearby fault could cause groundshaking in the study area, which could result in liquefaction or associated ground failure, such as lateral spreading or differential settlement which could in turn result in structural loss, injury, and death.

There are four levee reaches in the program study area that contain soils that may be subject to liquefaction: Sacramento River North and South Levee reaches, and the Sacramento and Yolo Bypass Levee reaches. Implementation of the proposed flood and recreation program elements would not substantially alter the composition of the subject levees or foundation soils or increase their susceptibility to liquefaction. The program does propose the construction of structures to reduce seepage and increase flood control (i.e., slurry walls, sheet pile walls, flood walls) and structures

associated with recreation elements, (trails, parks, and developed water access) that might sustain damage from groundshaking or liquefaction and endanger people during a seismic event.

However, the potential for failure of these structures in the four levee reaches from groundshaking would depend on the degree of levee saturation during an earthquake. A high level of saturation would likely only occur during a major flood event. The probability that a large regional earthquake would occur during a major flood event is relatively low, but such coincidence is not impossible. Nonetheless, because of the relative small likelihood of such coincidental events, and because the expected magnitude of groundshaking from large regional earthquakes is relatively low in the study area, the potential for failure or damage of any of proposed program flood or recreation structures in any of these four reaches from groundshaking and liquefaction is considered to be less than significant. No mitigation is required.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall ▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Closure structure ▪ Interior drain ▪ Jet grouting ▪ Relief wells	▪ Seepage berm ▪ Sheet pile wall ▪ Slurry cutoff wall ▪ Slope flattening ▪ Stability berm ▪ Rock slope protection ▪ Setback levee
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

This effect would occur in the Sacramento River North and South Levee reaches and the Sacramento and Yolo Bypass Levee reaches.

Effect GEO-3Finding	With Mitigation
Less than significant	N/A

Effect GEO-4: Accelerated Erosion and Sedimentation Resulting from Construction-Related Ground Disturbance

The grading, trenching, drilling, and other earthwork that would be conducted during construction of the various levee alternatives would result in substantial ground and vegetation disturbance. These disturbances would increase the hazard of erosion and could temporarily increase erosion and sedimentation rates above existing levels. Because most of the earthwork would be conducted on and immediately adjacent to the subject levee reaches, accelerated erosion and sedimentation resulting from construction-related ground and vegetation disturbance would not result in the loss of appreciable quantities of topsoil resources. In addition, most ground-disturbing activities would

occur during the typical construction season, when conditions are generally dry, further reducing the potential for construction-related erosion.

Site-specific measures that would control erosion would be described in more detail in the SWPPP, which is included in the environmental commitments of the program, described in Section 2.9 of Chapter 2, Alternatives. The SWPPP is a requirement of the NPDES General Construction Permit.

In addition, WSAFCA or its contractor would monitor turbidity in the Sacramento River to determine whether turbidity is being affected by construction and ensure that construction does not affect turbidity levels or acceptable sedimentation loads (as discussed in Section 3.3, Water Quality and Groundwater Resources). With these project-level actions, erosion and sediment-related effects would be less than significant. No mitigation is required.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall	▪ Seepage berm
	▪ Levee raise (in place)	▪ Sheet pile wall
	▪ Levee raise (adjacent)	▪ Slurry cutoff wall
	▪ Levee raise (full)	▪ Slope flattening
	▪ Closure structure	▪ Stability berm
	▪ Interior drain	▪ Rock slope protection
	▪ Jet grouting	▪ Setback levee
	▪ Relief wells	▪ Vegetation removal
Recreation	▪ Trails	▪ Developed water access
	▪ Riverside parks	▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect would occur in all nine program reaches.

Effect GEO-4 Finding	With Mitigation
Less than significant	N/A

Effect GEO-5: Structural Damage and Injury Resulting from Development on Expansive Soils

According to the soil survey for Yolo County, moderate to high shrink-swell potential (soil expansiveness) exists in the study area within the Sacramento and Yolo Bypass Levee reaches. Additionally, expansive soil and sediments were encountered at various depths below the levees in the study area during geotechnical investigations (Kleinfelder 2007). Expansive soils have the potential to compromise the structural integrity of proposed program elements such as slurry walls, sheet pile walls, flood walls, stop logs, and new recreation trails.

As previously discussed, WSAFCA would require the preparation of a preliminary soil report based on soil borings and, if expansive or weak soils are documented on site, a soils investigation detailing corrective action. These corrective actions likely would prevent structural damage to flood or recreation program alternatives proposed to be constructed on the expansive soils. This effect would significant, but implementation of Mitigation Measure GEO-MM-1 would reduce this effect to less than significant.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Jet grouting ▪ Sheet pile wall ▪ Slurry cutoff wall	▪ Closure structure ▪ Flood wall
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect would occur in all nine program reaches.

Effect GEO-5 Finding	With Mitigation
Significant	Less than significant

Mitigation

Mitigation Measure GEO-MM-1: Implement the Corrective Actions Identified as Part of a Project-Specific Geotechnical Report

WSAFCA will implement special engineering techniques identified in a project-specific geotechnical report, which may include using reinforced steel and drainage control devices, and/or over-excavating and backfilling with non-expansive soil. WSAFCA or its contractor will select one or more of the recommended measures in consultation with a qualified engineer and the City engineer before construction activities begin.

Effect GEO-6: Decrease in Local Soil Supply Resulting from Demand for Levee Material

The WSLIP activities have the potential to require borrow material for implementing levee improvements at a volume of approximately 6.2 million cubic yards. WSAFCA proposes to obtain borrow material from a local quarry or other authorized (i.e., permitted) location. The total supply available from all existing permitted sources is not known, but borrow material is generally considered in adequate quantities. This effect is considered less than significant based on this assumption and with consideration of the environmental commitment regarding soil supply

protection measures (see 2.9.1.22). This commitment addresses the process that will be followed for use of new sites (such as SMARA compliance, outlined in 3.4.2.1.1) and conservation of topsoil.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full)	▪ Seepage berm ▪ Stability berm ▪ Setback levee
Recreation	▪ Trails	▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect would occur in all nine program reaches.

Effect GEO-6 Finding	With Mitigation
Less than significant	N/A

Section 3.5
Transportation and Navigation

3.5.1 Introduction

This section describes the affected environment for transportation and navigation, the regulatory setting associated with transportation, the effects on transportation and navigation that would result from the proposed program, and the mitigation measures that would reduce these effects.

The key sources of data and information used in the preparation of this section are listed below:

- *City of West Sacramento General Plan*, revised December 2004
- *City of West Sacramento General Plan Background Report*, revised June 2000
- *City of West Sacramento Bicycle and Pedestrian Path Master Plan 1995*

3.5.1.1 Terminology

The following are definitions of key traffic and transportation terms used in this section.

- **Level of service (LOS)**: A scale used to determine the operating quality of a roadway segment or intersection based on volume-to-capacity (V/C) ratios or average delay experienced by vehicles on the facility. The levels range from A to F, with LOS A representing free-flow traffic and LOS F representing severe traffic congestion. Agencies adopt LOS standards that define the level of operations that are acceptable within their jurisdiction.
- **V/C ratio**: The number of vehicles that travel on a transportation facility divided by the vehicular capacity of that facility (the number of vehicles the facility was designed to convey).
- **Delay**: The additional travel time experienced by a vehicle or traveler because of inability to travel at optimal speed and/or stops due to congestion or traffic control.
- **Average daily traffic (ADT)**: Average traffic volume on the roadway section during a typical 24-hour day.
- **Annual average daily traffic (AADT)**: AADT is the total traffic volume for the year divided by 365 days.
- **Peak Hour:** This is an estimate of the peak hour traffic at all points on the state highway system.
- **Back and Ahead**: Back AADT, Peak Month, and Peak Hour usually represent traffic south or west of the count location. Ahead AADT, Peak Month, and Peak Hour usually represent traffic north or east of the count location.

Table 3.5-1 summarizes the ranges of V/C values and typical driving conditions for each LOS.

Table 3.5-1. Level of Service Definitions for Urban Streets

LOS	Intersection	Roadways
A	Uncongested operations, all queues clear in a single signal cycle. V/C = 0.00–0.60	Free flow, vehicle unaffected by other vehicles in traffic stream.
B	Uncongested operations, all queues clear in a single signal cycle. V/C = 0.61–0.70	Higher speed range of stable flow. Volume 50% of capacity or less.
C	Light congestion; occasional back-ups on critical approaches. V/C = 0.71–0.80	Stable flows with volumes not exceeding 75% of capacity.
D	Significant congestion of critical approaches, but intersection functional. Cars required to wait though more than one cycle during short peaks. No long queues formed. V/C = 0.81–0.90	Upper end of stable flow conditions. Volumes do not exceed 90% of capacity.
E	Severe congestion with some long-standing queues on critical approaches. Blockage of intersection may occur if traffic signal does not provide for protected turning movements. Traffic queue may block nearby intersections upstream of critical approaches. V/C = 0.91–1.00	Unstable flow at roadway capacity. Operating speeds 25 to 30 miles per hour (mph) or less.
F	Total breakdown; stop-and-go traffic operation. V/C > 1.00	Stop-and-go with operating speeds less than 30 mph.

Source: City of West Sacramento 2000.

3.5.2 Affected Environment

3.5.2.1 Regulatory Setting

Transportation analysis in the study area is guided by policies and standards set by local jurisdictions. Because the proposed program is located in the city of West Sacramento, the program should adhere to the adopted City transportation policies.

3.5.2.1.1 Federal

River and Harbors Appropriation Act of 1899

The River and Harbors Appropriation Act of 1899 addresses activities that involve the construction of dams, bridges, dikes, and other structures that cross any navigable water; that place obstructions to navigation outside established Federal lines; and that excavate from or deposit material in such waters. Such activities require permits from USACE. Navigable waters are defined in section 329.4 as:

> Those waters that are subject to the ebb and flow of the tide and/or are presently used, or have been used in the past, or may be susceptible for use to transport interstate or foreign commerce. A determination of navigability, once made, applies laterally over the entire surface of the water body, and is not extinguished by later actions or events which impede or destroy navigable capacity.

In the USACE Sacramento District, navigable waters of the United States in the project area that are subject to the requirements of the River and Harbors Appropriation Act include Sacramento River, American River, the Deep Water Ship Channel, and all waterways in the Sacramento–San Joaquin drainage basin affected by tidal action (U.S. Army Corps of Engineers 2003). Sections of the River and Harbors Act applicable to the proposed program are summarized below.

Section 9

Section 9 (33 USC 401) prohibits the construction of any dam or dike across any navigable water of the United States in the absence of Congressional consent and approval of the plans by the Chief of Engineers and the Secretary of the Army. Where the navigable portions of the water body lie wholly within the limits of a single state, the structure may be built under authority of the legislature of that state, if the location and plans or any modification thereof are approved by the Chief of Engineers and by the Secretary of the Army.

Section 10

Section 10 (33 USC 403) prohibits the unauthorized obstruction or alteration of any navigable water of the United States. This section provides that the construction of any structure in or over any navigable water of the United States, or the accomplishment of any other work affecting the course, location, condition, or physical capacity of such waters, is unlawful unless the work has been authorized by the Chief of Engineers.

3.5.2.1.2 Local

City of West Sacramento General Plan

Cities and counties use various criteria to determine acceptable LOS on their roadway systems. The Transportation and Circulation Element of the *City of West Sacramento General Plan* contains the following policy that may apply to the proposed program.

Goal A: To create and maintain a roadway network which will ensure the safe and efficient movement of people.

Policy 2: The City shall endeavor to maintain a Level of Service "C" on all streets within the city**,** except at intersections and on roadway segments within one-quarter mile of a freeway interchange or bridge crossing of the Deep Water Ship Channel [DWSC], barge canal, or Sacramento River, where a Level of Service "D" shall be deemed acceptable (City of West Sacramento 2004).

Table 3.5-2 quantifies the acceptable ADT of urban streets for corresponding LOS and roadway width.

Table 3.5-2. LOS Criteria for Roadway Segments

Facility Type	No. of Lanes	Maximum ADT per LOS				
		A	B	C	D	E
Residential	2	600	1,200	2,000	3,000	4,500
Residential collector with access	2	1600	3,200	4,800	6,400	8,000
Residential collector without access	2	6,000	7,000	8,000	9,000	10,000
Arterial, low access control (4+ stops/mile, many driveways, 25–35 mph)	2	9,000	10,500	12,000	13,500	15,000
	4	18,000	21,000	24,000	27,000	30,000
	6	27,000	31,500	36,000	40,500	45,000
Arterial, moderate access control (2–4 stops/mile, few driveways, 35–45 mph)	2	10,800	12,600	14,400	16,200	18,000
	4	21,600	25,200	28,800	32,400	36,000
	6	32,400	37,800	43,200	48,600	54,000
Arterial, high access control (1–2 stops/mile, no driveways, 45–55 mph)	2	12,000	14,000	16,000	18,000	20,000
	4	24,000	28,000	32,000	36,000	40,000
	6	36,000	42,000	48,000	54,000	60,000
Rural, 2-lane highway	2	2,400	4,800	7,900	13,500	22,900
Rural, 2-lane road, 24–36 feet, paved, shoulder	2	2,200	4,300	7,100	12,200	20,000
Rural, 2-lane road, 24–36 feet, paved, no shoulder	2	1,800	3,600	5,900	10,100	17,000

Source: City of West Sacramento 2006.

Policy 8: On-street truck parking shall be prohibited where such parking restricts adequate sight distances or otherwise poses a potentially hazardous situation.

Policy 10: The City shall attempt to confine truck traffic to designated truck routes. The City shall consider the additional weight and turning requirements of trucks in selecting truck routes.

Goal G: To promote pedestrian and bicycle travel as alternatives to automobile use.

Policy 1: The City shall create and maintain a safe and convenient system of pedestrian and bicycle pathways which encourages walking or bicycling as an alternative to driving.

Policy 3: Bicycle routes shall emphasize paths separated from vehicle traffic to the maximum extent possible, but shall also include bicycle lanes within public streets; bikeways may, however, be combined with pedestrian and vehicle routes, where appropriate.

Policy 4: The City shall limit on-street bicycle routes to those streets where the available roadway width and traffic volumes permit safe coexistence of bicycle and motor vehicle traffic.

Policy 7: To the extent practicable, bicycle and pedestrian pathways shall be included within open space areas and adjacent to waterways.

Solano County General Plan

The *Solano County General Plan* outlines policies, goals, and guidelines for project implementation with regards to transportation and circulation within the county. Goals and policies applicable to transportation consist of the following:

Goals

TC.G-1: Maintain and improve the County's transportation systems to enhance safety, resident access to basic needs, mobility, and convenience.

TC.G-2: Promote coordinated approaches to creating, maintaining and improving transportation corridors and facilities by working with other jurisdictions and transportation agencies in funding and implementing projects.

TC.G-3: Encourage land use patterns that maximize access and mobility options for commuting and other types of trips, and minimize traffic congestion, vehicle miles traveled (VMT), and greenhouse gas emissions.

TC.G-4: Encourage the use of alternative forms of transportation such as transit, walking and bicycling to alleviate congestion and promote recreation

Policies

TC.P-1: Maintain and improve current transportation systems to remedy safety and congestion issues, and establish specific actions to address these issues when they occur.

TC.P-3: Establish land use patterns that facilitate shorter travel distances and non-auto modes of travel, and limit the extent of additional transportation improvements and maintenance that may be needed with a more dispersed land use pattern.

TC.P-4: Evaluate proposals for new development for their compatibility with and potential effects on transportation systems.

TC.P-23: Evaluate and monitor the effects of water transportation and port activity on the levee system.

3.5.2.2 Environmental Setting

3.5.2.2.1 Transportation

This section describes the transportation characteristics of the study area, including the surrounding roadway network and transit, pedestrian, and bicycle facilities in the vicinity of the project site.

Roadways

Existing freeways within the study area are described below.

- **Interstate 80 (I-80)** is a major freeway that runs northeast–southwest in the northwestern corner of the city. I-80 and US Highway 50 (US 50) merge on the westbound (WB) lanes heading to San Francisco and split on the eastbound (EB) lanes. After the EB split, I-80 runs northeast toward Reno and connects to the cities on the northern side of the Sacramento metropolitan area.
- **US 50** is a major freeway extending from I-80 in West Sacramento through the city of Sacramento and heading east. US 50 is co-designated as Business 80, also known as the Capital City Freeway, between I-80 and State Route (SR) 99 in the West Sacramento and Sacramento area. In the study area, US 50 is a six- to eight-lane freeway with interchanges at Harbor Boulevard and Jefferson Boulevard and a partial interchange at South River Road.

The following are the major arterial streets that serve the study area.

- **West Capitol Avenue (SR 275)** is an east-west arterial that runs between I-80 near the western city limits of West Sacramento and the Tower Bridge at the Sacramento River. The roadway width varies between two, four, and six lanes.
- **Reed Avenue/Sacramento Avenue/C Street (SR 84)** is an east-west arterial that runs between I-80 near the western city limits of West Sacramento and the I Street Bridge at the Sacramento River. The roadway width varies between two and four lanes.
- **Industrial Boulevard/Lake Washington Boulevard** is a four-lane arterial that serves the West Sacramento area south of US 50/Business 80. The roadway provides a continuous route from Jefferson Boulevard on the east to Enterprise Boulevard on the west, crossing over the Palamidessi Bridge.
- **Linden Road** is an east-west arterial that serves the Southport area of West Sacramento. Linden Road extends from South River Road on the east, crosses Jefferson Boulevard, and intersects Jefferson Boulevard again, approximately 1 mile south of the northern crossing.
- **Jefferson Boulevard (SR 84)** is a major arterial and truck route that extends from Sacramento Avenue to south of city limits. Jefferson Boulevard is a four-lane road from Sacramento Avenue to just south of South Linden Road. The remaining portion of the roadway within the study area is composed of two lanes.
- **Harbor Boulevard** is a north-south arterial that runs through the western portion of the city. The roadway width varies between two and four lanes.
- **Enterprise Boulevard** serves the western industrial area south of I-80 and also serves as an arterial. This roadway is two and four lanes wide and connects to the regional freeway system via an interchange at I-80.
- **Southport Parkway** is an arterial that runs along the western side of the Southport area. This roadway is four lanes wide from Lake Washington Boulevard to Promenade Street, and then narrows down to two lanes until it terminates at Jefferson Boulevard near the southern edge of the city. The road provides access to the residential areas on the western side of Southport.

Local roads that run adjacent to or along the crest of the levees in the study area include Riverbank Road (Sacramento River North Levee), River Crest Drive (Sacramento River North Levee), and South River Road (Sacramento River North Levee and Sacramento River South Levee).

Average Daily Traffic

Table 3.5-3 shows the annual average daily traffic for major segments of I- 80 and US 50 in the study area. These segments of the highway will likely be used for hauling construction supplies for program implementations.

Table 3.5-3. AADT for Highways in the Program Area

Highway	Segment	Back AADT	Ahead AADT
I-80	Junction with US 50	145,000	85,000
I-80	Junction with SR 84 (Reed Avenue)	85,000	90,000
I-80	West El Camino Avenue Interchange	90,000	87,000
US 50	Junction with I-80	–	85,000
US 50	Harbor Boulevard Interchange	85,000	116,000

Source: California Department of Transportation 2009.

Table 3.5-4 displays the ADT counts for streets incorporated into the City's truck route map (Figure 3.5-1) (City of West Sacramento 2007b). Many of these streets would potentially be involved in hauling construction supplies and equipment to the project sites since parts of the proposed program would be spread along the perimeter of the city.

Level of Service

Table 3.5-5 summarizes existing daily LOS for roadways located within or near the study area. The table shows that under existing conditions, most of roadways are operating within adopted LOS standards. Only one roadway, Jefferson Boulevard, is carrying traffic volumes that are approaching capacity. The existing ADT of Jefferson Boulevard between Arlington and SR 275/US 50 is shown to exceed LOS standards.

Table 3.5-5. Existing Roadway LOS

Roadway	LOS	V/C
West Capitol Avenue, west of Harbor Blvd	A	0.40
West Capitol Avenue, west of Merkley Ave	A	0.55
West Capitol Avenue, west of Jefferson Blvd	A	0.42

* Exceeds adopted LOS standard.

Table 3.5-6 summarizes intersection LOS values that have been calculated for typical a.m. and p.m. peak periods. The following three intersections are shown to exceed LOS standards during both the a.m. and p.m. peak hours:

- Jefferson Boulevard and US 50/Park Boulevard,
- Jefferson Boulevard and Stone Boulevard, and
- Jefferson Boulevard and F Street.

The following three additional intersections are shown to exceed standards only during the p.m. peak hour:

- Sacramento Avenue and Bryte Avenue,
- West Capitol Avenue and SR 275 Ramps, and
- Jefferson Boulevard and SR 275/US 50 WB.

All other intersections located in and near the study area are shown to be operating within the adopted City standards.

Parking

On-street parking is available on most streets within West Sacramento. The City does not have any public parking lots. Construction projects are subject to off-street parking standards as defined in the City's Zoning Ordinance (City of West Sacramento 2000).

Railroads

The Sierra Northern Railway is the local freight rail operator. The Sierra Northern Railway has a line that runs northwest to Woodland. It also provides rail service to the Port of West Sacramento and the industrial section of West Sacramento. The Sierra Northern Railway handles approximately 8,000 carloads annually, and is used for carrying various commodities. Sierra Northern Railway does have trains that carry passengers; however, these lines are not located within the study area. The Sierra Northern Railway interchanges with both the Union Pacific Railroad (UPRR) and the Burlington Northern Santa Fe Railroad (BNSF). The UPRR and BNSF provide long haul service to and

from the city of West Sacramento. AMTRAK provides passenger rail service to the area; however, although the rail runs through the city, there are no stops in the city limits and the closest stop is in the City of Sacramento (City of West Sacramento 2009b). See Figure 3.5-2 for the layout of rail lines in the city of West Sacramento.

Transit Facilities

The Yolo County Transportation District operates 26 bus routes in Yolo County. Yolobus transit service operates within the city of West Sacramento and provides access to the surrounding communities, including Davis, Winters, Woodland, downtown Sacramento, Sacramento International Airport, Brooks, Cache Creek Casino, Capay, Dunnigan, Esparto, Guinda, Madison, Knights Landing, Rumsey, and Vacaville. It also provides connections to other public transportation systems, including Unitrans, Citylink Amtrak in Davis, and Regional Transit's bus and light rail systems in Sacramento (Yolo County Transportation District 2009).

Bikeways

Bicycle facilities are currently available within the program vicinity. The City has a Bicycle and Pedestrian Path Master Plan, which identifies existing path facilities, opportunities, constraints, destination points, and design standards. As stated in the plan, major arterial roads as well as several minor arterial roads throughout the city have bike lanes or bike-accessible shoulders (City of West Sacramento 1991). The main bikeway in the City is located on West Capitol Avenue, which connects the Sacramento bikeway to the Yolo County bikeway, which then connects to Davis bikeways. Another major route is located on Sacramento Avenue.

The Clarksburg Branch Line Trail is an off-street path that runs south from the Barge Canal down to South River Road near the southern end of the city limits. The Roland Hensley Bike Park lies on the western end of the city limits, just north of I-80, and provides access to the off-street bike path that crosses the Yolo Bypass Levee. Bike accessible areas that run adjacent to or on top of levees include S. River Road south of the Barge Canal, Riverbank Road (Sacramento River South Levee), and N. Harbor Boulevard (Sacramento River North Levee) (City of West Sacramento 2009a).

Airports

Airports in the area are Sacramento International Airport, Sacramento Executive Airport, Mather Airport, and Franklin Field. Sacramento International Airport is Sacramento County–owned and is located approximately 7 miles north of the city of West Sacramento, between Sacramento and Woodland along Interstate 5 (I-5). The Executive Airport is owned by Sacramento County and is located 1.5 miles to the east of West Sacramento, in the city of Sacramento. Mather Field is a cargo airfield located approximately 11 miles east of the city in Rancho Cordova. Franklin Field is owned by Sacramento County and is located approximately 16 miles south of the city in Elk Grove.

3.5.2.2.2 Navigation

Most of the waterways in the immediate vicinity of the city of West Sacramento are public waterways. These public waterways consist primarily of the Sacramento River, the DWSC, and the Barge Canal. USACE, pursuant to the Rivers and Harbors Act, maintains jurisdiction over all navigable waterways (including non-Federal navigable streams, creeks, marshes, and diked lands) and requires a permit for any work within these waterways.

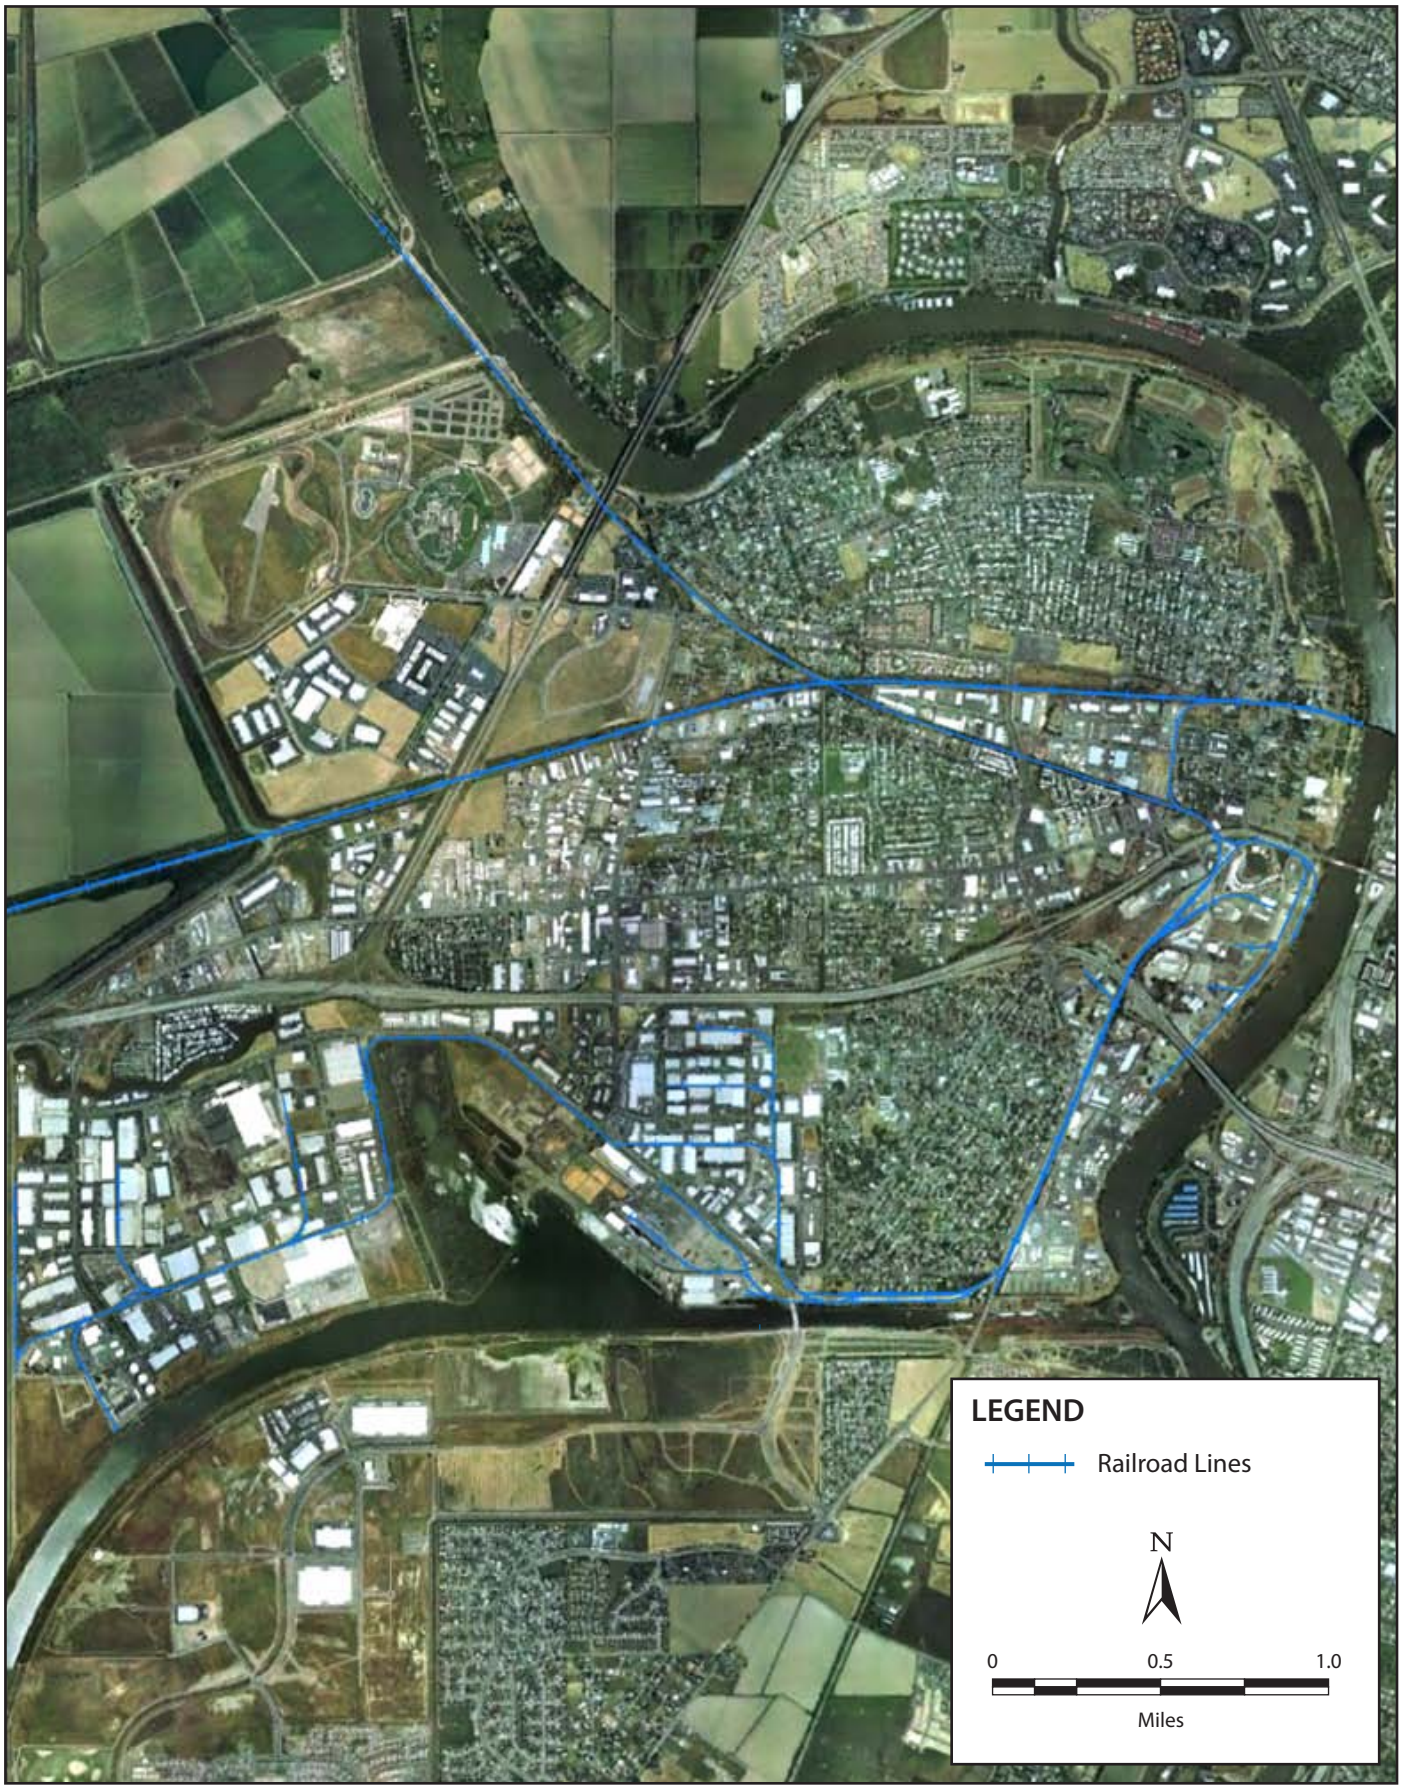
Navigation in the Sacramento River is limited to recreational watercraft (e.g., personal watercraft and small tour boats) because the river is too small and fluctuating water levels prevent the accommodation of large commercial vessels. The DWSC runs from the Delta to the Port of Sacramento, providing commercial shipping access to the Sacramento region. With a water depth of approximately 30 feet, the DWSC is approximately 450 feet across in the section running between the DWSC West and DWSC East levees (City of West Sacramento 2009c).

The Barge Canal connects the DWSC to the Sacramento River. The Barge Canal and navigational lock were originally built to allow recreational, construction, and small commercial vessels to access the Sacramento River from the Port of Sacramento. However, commercial traffic has declined on the Sacramento River and the locks are not currently operational. Silting has occurred on the mouth of the lock on the Sacramento River end of the facility (City of West Sacramento 2009b).

Minor waterways in the area include Bridgeway Lake, Lake Washington, and the Barge Canal Recreational Access. These areas are limited to small recreational watercraft. Bridgeway Lake and Lake Washington are not adjacent to the levees analyzed in this document and would not be affected by the proposed program. The Barge Canal Recreational Access is located between the Port South Levee and the Port North Levee west of the Stone Locks.

The Broderick Boat Ramp is located in the northeast corner of the city of West Sacramento and provides recreational watercraft access to the Sacramento River. This feature is located along the Sacramento River North Levee. The City, in partnership with the State Department of Boating and Waterways, constructed improvements during fall of 2008 that doubled the effective capacity of the boat ramp.

3.5.3 Environmental Consequences



This section describes the analysis of effects relating to transportation and navigation for the proposed program. It describes the methods used to determine the effects of the proposed program and lists the thresholds used to conclude whether an effect would be significant. Measures to mitigate (i.e., avoid, minimize, rectify, reduce, eliminate, or compensate for) significant effects accompany the discussion of each effect. How effects differ among reaches is discussed as applicable.

3.5.3.1 Assessment Methods

The proposed program comprises the construction of levee alternatives along multiple separate reaches throughout the city of West Sacramento. Because of the earthwork involved and the need for materials deliveries, construction would intermittently generate substantial volumes of traffic. Once the construction is completed, maintenance needs would be very limited. Analysis of traffic effects therefore concentrated on the construction of levee alternatives.

For the purposes of analysis, the effects of these project activities were divided into two impact mechanism categories: (1) truck and worker trip effects on roadway operation and circulation, and (2) temporary partial obstructions in navigable waterways from barge trips and waterside levee construction activities.

Because the construction site would vary on any given period and the construction phase of any specific site is expected to be short-term, no quantitative LOS analysis was performed. Quantitative information (truck trips, treatment location, and number of workers) would be developed at a project level as projects are proposed.

00875.07 EIR (8-09)

Figure 3.5-2
City of West Sacramento Railroads Lines

3.5.3.2 Determination of Effects

For this analysis, a transportation effect was considered significant if it would result in any of the following outcomes, which are based on professional practice, State CEQA Guidelines Appendix G, *City of West Sacramento General Plan Policy Document*, and the City's LOS policies:

- cause an increase in traffic that is substantial in relation to the existing traffic load and capacity of the street system (i.e., result in a substantial increase in the number of vehicle trips, the V/C ratio on roads, or congestion at intersections);
- cause, either individually or cumulatively, exceedance of a LOS standard established by the City and/or the California Department of Transportation (Caltrans) for designated roads or highways;
- substantially alter present patterns of circulation or movement;
- substantially increase hazards because of a design feature (e.g., sharp curves or dangerous intersections) or incompatible uses (e.g., slow-moving vehicles);
- result in inadequate emergency access;
- result in inadequate parking capacity; or
- conflict with adopted policies, plans, or programs supporting alternative transportation (e.g., bus turnouts, bicycle racks); or substantially impede navigation of watercraft as a result of the installation of cofferdams or the staging of barges within navigable sections of the surrounding waterways.

3.5.3.2.1 Effect Assumptions

It has not yet been determined whether any of the treatment alternatives would require temporary or long-term railway realignments.

3.5.3.3 Effects and Mitigation Measures

3.5.3.3.1 No Action Alternative

Under the No Action Alternative, there would be no change in the characteristics of the regional transportation system, local roadways, or navigation in and around the city of West Sacramento. It is likely that the levee roads and other roads in the study area would continue to be maintained by Yolo County and the city of West Sacramento. No road modifications, including the raising and building of new roads, would occur, and navigation would not change under the No Action Alternative. No construction related closures or delays would occur.

However, without levee improvements, there is a continued risk of levee failure or collapse, which would trigger widespread flooding and damage to the city's utilities, roadways, major interstate transportation corridors, and other infrastructure systems. The severity and magnitude would depend on the location of the levee breach, severity of the storm, and river flows at the time of a potential levee failure. A catastrophic flood event in West Sacramento would disrupt state and interstate highway, rail, and shipping traffic, causing long-term effects on the region's and state's economy and ability to move people and goods in normal circulation patterns. As stated in Section 2.4.2, No Action Alternative, West Sacramento has one of the most comprehensive transportation

networks on the west coast. Its central geographic location and extensive north-south, east-west highway access has made it a major distribution center. High volumes of truck and passenger traffic pass through the city on I- 80 and US-50/Business 80 every day, with truck traffic transporting approximately $63 billion worth of cargo annually through West Sacramento. Major transcontinental rail lines also pass through the city (transporting $5 billion in goods annually) and the Port of West Sacramento runs domestic and international shipping services. The normal circulation patterns of all of these transportation modes would be significantly affected if widespread flooding were to occur. In addition, flooding could result in substantial disruption to critical facilities and the city's emergency response capacity and critical lifelines of West Sacramento.

3.5.3.3.2 Flood and Recreation Program Alternatives

Effect TN-1: Temporary Increase in Traffic Volumes from Construction-Generated Traffic

Implementation of the program would require hauling of construction equipment and materials along major highways and through surface streets in the city of West Sacramento. The construction schedule, exact treatment location, number of required workers, and number of trucks have not been determined at this time. The roadways used by construction traffic would vary, depending on the specific construction site. Nonetheless, the trucks and workers required for the treatment would temporarily increase the daily and peak hour traffic along specified routes and could potentially worsen the traffic operation along these roadways, particularly if numerous trips occur during the morning or afternoon peak traffic periods. Traffic would return to normal levels once construction is completed. However, during construction, this effect could cause a substantial increase in the AADT along major highways and/or cause an exceedance of LOS standards for any of the haul route roadways. Implementation of the Traffic Control and Road Maintenance Plan environmental commitment, described in Section 2.9 of Chapter 2, Alternatives, could reduce the intensity of this effect but may not reduce it to a less than significant level. There is no feasible mitigation. Because the number of required truck trips has not been determined at this time, it is assumed that this effect would be significant and unavoidable.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall ▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Closure structure ▪ Interior drain ▪ Jet grouting ▪ Relief wells	▪ Seepage berm ▪ Sheet pile wall ▪ Slurry cutoff wall ▪ Slope flattening ▪ Stability berm ▪ Rock slope protection ▪ Setback levee ▪ Vegetation removal
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect would occur in all nine program reaches.

Effect TN-1 Finding	With Mitigation
Significant – Significant and unavoidable	No feasible mitigation

Effect TN-2: Temporary Road Closures or Restricted Access to Parking on the Levee Crown or Roads That Run Adjacent to the Levee

Implementation or operation of the program may require the removal of roads, or road sections, that run along the top of, or adjacent to, the levee crown. Additionally, equipment involved in construction (or operations; e.g., the placement of stop logs via crane) may require adjacent roads to be temporarily or permanently realigned, or temporarily closed. The removal of roads or road sections, as well as the road closings, would render the street inoperable and detour normal traffic to adjacent streets. In some cases such as The Rivers EIP on the Sacramento River North Levee where construction activities would occur on the only access road to residential homes, access for homeowners during construction may be impossible. The detouring of traffic would increase daily traffic quantities on roads in the surrounding areas. The environmental commitment to develop and implement a traffic control and road maintenance plan, and for temporary relocation assistance, described in Section 2.9, in Chapter 2, Alternatives, in addition to potential road realignments, would reduce this effect, but not always to a less-than-significant level . Roads removed during treatment construction would be rebuilt following the construction of the levee treatment, restoring traffic levels to pre-program conditions.

Road closure on the Port North Levee could potentially block vehicle access to the Port of West Sacramento, a hub for shipping commerce in the Sacramento Valley. In order to ensure that vehicular access to the Port is not lost during construction, the program proponent has committed to coordinating construction schedules with the Port of Sacramento (described under Section 2.9 in Chapter 2, Alternatives). With implementation of this environmental commitment, access to the Port would be maintained and this effect would be less than significant. No mitigation is required.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall ▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Closure structure ▪ Interior drain ▪ Jet grouting ▪ Relief wells	▪ Seepage berm ▪ Sheet pile wall ▪ Slurry cutoff wall ▪ Slope flattening ▪ Stability berm ▪ Rock slope protection ▪ Setback levee
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect would occur in all nine program reaches. However, the extent of the effect at the Port North Levee reach could be greater as road closure on the Port North Levee could potentially block vehicle access to the Port of West Sacramento, as discussed above.

Effect TN-2 Finding	With Mitigation
Less than significant – Significant and unavoidable	N/A

Effect TN-3: Increase in Safety Hazards Attributable to Construction-Generated Traffic

The maneuvering of construction-related vehicles and equipment among the general-purpose traffic on local roads could cause safety hazards. However, execution of the environmental commitment to develop and implement a traffic control and road maintenance plan, described in Section2.9 of Chapter 2, Alternatives, would minimize construction-related traffic hazards, and would reduce the intensity of this effect. This effect would be less than significant. No mitigation is required.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall	▪ Seepage berm
	▪ Levee raise (in place)	▪ Sheet pile wall
	▪ Levee raise (adjacent)	▪ Slurry cutoff wall
	▪ Levee raise (full)	▪ Slope flattening
	▪ Closure structure	▪ Stability berm
	▪ Interior drain	▪ Rock slope protection
	▪ Jet grouting	▪ Setback levee
	▪ Relief wells	▪ Vegetation removal
Recreation	▪ Trails	▪ Developed water access
	▪ Riverside parks	▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect would occur in all nine program reaches.

Effect TN-3 Finding	With Mitigation
Less than significant	N/A

Effect TN-4: Increase in Emergency Response Times

Emergency access to the program vicinity could be affected by construction of the proposed program, and construction-related traffic could delay or obstruct the movement of emergency vehicles. However, execution of the environmental commitment to develop and implement a traffic control and road maintenance plan, described in Section2.9 of Chapter 2, Alternatives, would minimize construction-related effects on emergency response times. This effect would be less than significant. No mitigation is required.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall	▪ Seepage berm
	▪ Levee raise (in place)	▪ Sheet pile wall
	▪ Levee raise (adjacent)	▪ Slurry cutoff wall
	▪ Levee raise (full)	▪ Slope flattening
	▪ Closure structure	▪ Stability berm
	▪ Interior drain	▪ Rock slope protection
	▪ Jet grouting	▪ Setback levee
	▪ Relief wells	▪ Vegetation removal
Recreation	▪ Trails	▪ Developed water access
	▪ Riverside parks	▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect would occur in all nine program reaches.

Effect TN-4 Finding	With Mitigation
Less than significant	N/A

Effect TN-5: Inadequate Parking Supply to Meet Parking Demand for Construction Equipment and Construction Workers

A parking area for construction workers and trucks would be provided at staging areas adjacent to a work site or areas within the levee right-of-way; therefore, this effect would be less than significant No mitigation is required.

Effect TN-5 Finding	With Mitigation
Less than significant	N/A

Effect TN-6: Disruption of Alternative Transportation Modes as a Result of Temporary Road Closures

Although most of the construction of the proposed program would take place within the project right-of-way, temporary road closures would be needed in some areas, which could interfere with transit services or bicycle travel along these roads. Implementation of the Traffic Control and Road Maintenance Plan environmental commitment, described in Section2.9 of Chapter 2, Alternatives, would minimize construction-related traffic conflicts with alternative modes of transportation. Therefore, this effect would be less than significant. No mitigation is required.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Jet grouting ▪ Relief wells ▪ Sheet pile wall ▪ Slurry cutoff wall	▪ Sheet pile wall ▪ Slurry cutoff wall ▪ Slope flattening ▪ Stability berm ▪ Rock slope protection ▪ Setback levee
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

This effect would potentially occur in all except the following reaches: South Cross Levee, Port North and Port South Levees, DWSC West and DWSC East Levees, Yolo Bypass Levee, and Sacramento Bypass Levee.

Effect TN-6 Finding	With Mitigation
Less than significant	N/A

Effect TN-7: Temporary Changes to Navigation as a Result of Construction

Implementation of flood and recreation program elements could require in-water work that could cause a temporary reduction in navigability in the Sacramento River and the DWSC. For example, in-water work may be required for flood control activities such as the placement of rock slope protection, full levee raises, or waterside slope flattening or recreation element work such as the placement of over or in-water structures, all of which may decrease the available space for navigation of watercraft. Given the width of the DWSC, this could potentially reduce available navigable widths to the point of being inaccessible to commercial ships bound to and from the Port of West Sacramento. Navigation would return to normal following completion of the rock slope protection alternative.

WSAFCA will implement the environmental commitment described in Section 2.9 of Chapter 2, Alternatives, to reduce construction-related effects on navigation. This environmental commitment includes measures to ensure that:

- construction will not occur during major summer holiday periods; and
- warning signs and buoys will be posted at, upstream of, and downstream of all construction equipment, sites, and activities.

The section of the Sacramento River within the study area is wide enough that watercraft would still be able to pass during in-water construction work. Thus, in-channel construction activity would not substantially impede navigation in the Sacramento River, and construction-related effects would be less than significant. No mitigation is required.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall ▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Closure structure ▪ Interior drain ▪ Jet grouting ▪ Relief wells	▪ Seepage berm ▪ Sheet pile wall ▪ Slurry cutoff wall ▪ Slope flattening ▪ Stability berm ▪ Rock slope protection ▪ Setback levee
Recreation	▪ Developed water access	▪ Riverside parks

Affected Reaches

This effect would occur primarily in the Sacramento River North and South Levee Reaches, the Port North and South Levee Reaches, and the DWSC West and East Levee reaches. The South Cross Levee, Yolo, and Sacramento Bypass Levee reaches do not have water bodies that support navigation.

Effect TN-7 Finding	With Mitigation
Less than significant	N/A

Effect TN-8: Increased Circulation Opportunities for Cyclists and Pedestrians

Construction of recreational biking and walking trails, as well as waterfront features, would provide increased circulation for bikers and pedestrians once construction is completed. Implementation of these aspects of the program would potentially reduce the number of cyclists and pedestrians on major roadways by providing alternative routes, thereby making roads safer in the study area. Construction of trails would occur concurrently with levee treatment implementation and would not further degrade LOS on roadways affected by the program. This effect would be beneficial.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

This effect would occur in the reaches for which recreation program alternatives are proposed. Although different recreation program alternatives are proposed, this effect would occur in the Sacramento River North and South Levees, Port North and South Levees, South Cross Levee, DWSC East Levee, Yolo Bypass and Sacramento Bypass Levees.

Effect TN-8 Finding	With Mitigation
Beneficial	N/A

Effect TN-9: Effect on Boating Amenities along the Sacramento River

Construction of developed water access elements such as public docks and a marina that are proposed as part of the program would increase navigational access to the Sacramento River. These features would not substantially impede navigation on the Sacramento River as the marina would be located in an inlet, away from normal boat traffic, and the docks would be of a consistent profile with existing area docks. This effect would be beneficial.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Recreation	▪ Developed water access	▪ Special projects

Affected Reaches

This effect would occur in the Sacramento River North Levee, and Port North and South Levees.

Effect TN-9 Finding	With Mitigation
Beneficial	N/A

Effect TN-10: Temporary Loss of Service to Railroads

Implementation of program alternatives could potentially disrupt railroad service along rail lines that intersect or that are adjacent to program levees, including the Sierra Northern, UPRR, BNSF, and AMTRAK rail lines. Construction activities could require either the temporary closure of rail lines to

accommodate construction vehicles or result in temporary removal of tracks due to treatment implementation, resulting in a temporary loss of service to the lines listed above. The program proponent would minimize any disruption to service by using the most recent and available construction methods to expedite construction activities and return service to affected railroads. Following construction, closed rail lines would be reopened and removed tracks would be replaced, restoring service to pre-program conditions. Implementation of the railroads environmental commitment, described in Section 2.9 of Chapter 2, Alternatives, would reduce the duration of the loss of service, but may not always reduce this effect to a level that would be considered less than significant. Therefore, the temporary loss of service to railroads would be less than significant to significant and unavoidable.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall ▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Jet grouting	▪ Seepage berm ▪ Sheet pile wall ▪ Slurry cutoff wall ▪ Slope flattening ▪ Stability berm ▪ Rock slope protection

Affected Reaches

This effect would potentially occur in the following reaches: Sacramento River North Levee, Port North Levee, Yolo Bypass Levee, and the Sacramento Bypass Levee. These reaches all have a railroad line that either runs adjacent to it, on top of it, or that intersects the reach.

Effect TN-10 Finding	With Mitigation
Less than significant – Significant and unavoidable	N/A

Section 3.6

Air Quality and Climate Change

3.6.1 Introduction

This section describes the affected environment and environmental consequences for air quality and climate change, respectively, in individual section for ease of review. It describes the existing air quality and climate conditions in the study area and evaluates the potential air quality and climate change effects associated with the program implementation.

Although construction activities would result in temporary effects on air quality in the study area, the program would comply with all Federal, state, and local air quality regulations. Where a potentially significant air quality or climate change effect is identified, mitigation measures are recommended to reduce the level of expected effects.

The key sources of data and information used in the preparation of this section are listed below. Additional information is available in Appendix E.

- *Handbook for Assessing and Mitigating Air Quality Impacts* (Yolo-Solano Air Quality Management District 2007)
- *Guide to Air Quality Assessment in Sacramento County* (Sacramento Metropolitan Air Quality Management District 2004)
- *CEQA and Climate Change*, *Evaluating and Addressing Greenhouse Gas Emissions from Projects Subject to the California Environmental Quality Act* (California Air Pollution Control Officers Association 2008)

3.6.2 Affected Environment

This section describes the regulatory settings and environmental settings for air quality and climate change, respectively. Air quality and climate change are addressed in individual sections for ease of review.

3.6.2.1 Air Quality Regulatory Setting

The study area and surrounding areas are subject to air quality regulations developed and implemented at the Federal, state, and local levels. At the Federal level, EPA is responsible for implementation of the Clean Air Act (CAA). Some portions of the CAA (e.g., certain mobile-source and other requirements) are implemented directly by EPA. Other portions of the CAA (e.g., stationary-source requirements) are implemented by state and local agencies.

Responsibility for attaining and maintaining air quality in California is divided between the California Air Resources Board (CARB) and regional air quality districts. Areas of control for the regional districts are set by CARB, which divides the state into air basins. These air basins are defined by topography that limits air flow access, or by county boundaries. Plans, policies, and regulations relevant to the program are discussed below.

3.6.2.1.1 Federal

Clean Air Act

The CAA establishes Federal air quality standards, known as National Ambient Air Quality Standards (NAAQS), and specifies future dates for achieving compliance. The standards are divided into primary and secondary standards; the former are set to protect human health within an adequate margin of safety, and the latter to protect environmental values, such as plant and animal life.

The 1990 amendments to the CAA identify specific emission-reduction goals for areas not meeting the NAAQS. These amendments require both a demonstration of reasonable further progress toward attainment and an incorporation of additional sanctions for failure to attain or meet interim milestones. The sections of the CAA that are most applicable to the proposed program are Title I (Non-attainment Provisions) and Title II (Mobile Source Provisions). Title I of the CAA identifies attainment, non-attainment, and unclassifiable areas with regard to criteria pollutants and sets deadlines for all areas to reach attainment for the following criteria pollutants: ozone, carbon monoxide (CO), respirable particulates (PM10, particulate matter less than 10 microns in diameter), nitrogen dioxide (NO_2), sulfur dioxide (SO_2), and lead. The NAAQS were amended in July 1997 to include the 8-hour ozone standard and a NAAQS for fine particulates (PM2.5, particulate matter less than 2.5 microns in aerodynamic diameter). Applicable NAAQS for these criteria pollutants are presented in Table 3.6-1.

Table 3.6-1. National and California Ambient Air Quality Standards

		Federal (1)		
Pollutant	**Averaging Time**	**Primary**	**Secondary**	**California (2)**
Ozone	8 hour (3)	0.075 ppm	0.075 ppm	0.07 ppm
	1 hour	No standard	No standard	0.09 ppm
Carbon monoxide—CO	8 hour	9 ppm	No standard	9 ppm
	1 hour	35 ppm	No standard	20 ppm
Respirable particulate matter—PM10	24 hour (4)	150 µg/m^3	150 µg/m^3	50 µg/m^3
	Annual	No standard	No standard	20 µg/m^3
Fine particulate matter—PM2.5	24 hour (5)	35 µg/m^3	35 µg/m^3	35 µg/m^3
	Annual	15 µg/m^3	15 µg/m^3	12 µg/m^3
Nitrogen dioxide—NO_2	Annual	0.053 ppm	0.053 ppm	0.03 ppm
	1 hour	No standard	No standard	0.18 ppm
Sulfur dioxide—SO_2	Annual	0.03 ppm	No standard	No standard
	24 hour	0.14 ppm	No standard	0.04 ppm
	3 hour	No standard	0.50 ppm	No standard
	1 hour	No standard	No standard	0.25 ppm
Lead	30 day	No standard	No standard	1.5 µg/m^3
	Calendar quarter	1.5 µg/m^3	1.5 µg/m^3	No standard
	Rolling 3 month	0.15 µg/m^3	0.15 µg/m^3	No standard

Pollutant	Averaging Time	Federal (1) Primary	Federal (1) Secondary	California (2)

Source: California Air Resources Board 2009a.

ppm = parts per million; µg/m^3 = micrograms per cubic meter.

[1] National standards are not to be exceeded more than once a year.

[2] California standards for ozone, CO, PM10, PM2.5, NO_2, and SO_2 (1 and 24 hour) are values that are not to be exceeded. All others are not to be equaled or exceeded.

[3] To attain the Federal ozone standard, the 3-year average of the fourth-highest daily maximum 8-hour average ozone concentrations measured at each monitor within an area over each year must not exceed 0.075 ppm.

[4] To attain the Federal PM10 standard, the expected number of days per calendar year with a 24-hour average concentration above 150 µg/m^3 must be equal to or less than 1.

[5] To attain the Federal PM2.5 standard, 98% of the daily concentrations, averaged over 3 years, must be equal to or less than 35 µg/m^3.

The CAA requires states to submit a SIP for areas in non-attainment for Federal standards. The SIP, which is reviewed and approved by the EPA, must demonstrate how the Federal standards would be achieved. Failing to submit a plan or secure approval could lead to denial of Federal funding and permits. In cases where the SIP is submitted by the state but fails to demonstrate achievement of the standards, EPA is directed to prepare a Federal implementation plan.

Title II of the CAA contains a number of provisions regarding mobile sources, including requirements for reformulated gasoline, new tailpipe emission standards for cars and trucks, oxides of nitrogen (NO_X) standards for heavy-duty vehicles, and a program for cleaner fleet vehicles.

General Conformity Regulation

EPA enacted the Federal General Conformity regulation (40 CFR Parts 5, 51, and 93) in 1993. The General Conformity rule applies to Federal actions located in non-attainment areas that do not include stationary industrial sources requiring preconstruction air quality permits from local air pollution control agencies. The purpose is to ensure that Federal actions do not generate emissions that interfere with state and local agencies' SIPs and emission-reduction strategies.

The General Conformity rule applies in air quality non-attainment or maintenance areas, and only to direct and indirect emissions associated with the portions of any Federal action for which a Federal permitting agency has the authority to impose emission reductions. Since the program is within USACE's jurisdiction and would require a permit from USACE, all direct and indirect emissions generated by the program construction are subject to General Conformity.

The program would generate air pollutant emissions from construction sites in Yolo County and would generate indirect on-road emissions in both Yolo County and Sacramento County, both of which are designated a serious non-attainment area for ozone NAAQS. Yolo County is designated a non-attainment area for PM2.5 NAAQS and Sacramento County is a moderate non-attainment area for PM10 NAAQS. Based on those designations, the General Conformity thresholds are:

- 50 tons/year of NO_X,
- 50 tons/year of reactive organic gasses (ROG),
- 100 tons/year of PM2.5 for emissions occurring in Yolo County, and
- 100 tons/year of PM10 for emissions occurring in Sacramento County.

All emission sources include in-water equipment, on-land non-road equipment, on-road haul trucks, and on-road commute vehicles that operate on program components are required to comply with the General Conformity thresholds. If the annual emissions exceed the applicability thresholds, then the applicant must consult with the air quality district to confirm that the county-wide emission budget prepared for the SIP included the general types of activity proposed by the applicant.

Federal Tailpipe Emission Standards

To reduce emissions from off-road diesel equipment, on-road diesel trucks, and harbor craft, EPA established a series of increasingly strict emission standards for new engines. New construction equipment used for the program, including heavy-duty trucks, off-road construction equipment, tugboats, and barges, will be required to comply with the emission standards.

3.6.2.1.2 State

California Clean Air Act

In 1988, the state legislature adopted the California Clean Air Act (CCAA), which established a statewide air pollution control program. The CCAA requires all areas of the state to achieve and maintain the California Ambient Air Quality Standards (CAAQS) by the earliest practical date. The CAAQS incorporate additional standards for most criteria pollutants and set standards for other pollutants recognized by the state. In general, the CAAQS are more stringent than the corresponding NAAQS.

CARB and local air districts bear responsibility for achieving California's air quality standards, which are to be achieved through district-level air quality management plans that would be incorporated into the SIP. In California, EPA has delegated authority to prepare SIPs to CARB, which, in turn, has delegated that authority to individual air districts. CARB traditionally has established state air quality standards, maintaining oversight authority in air quality planning, developing programs for reducing emissions from motor vehicles, developing air emission inventories, collecting air quality and meteorological data, and approving SIPs.

Responsibilities of air districts include overseeing stationary source emissions, approving permits, maintaining emissions inventories, maintaining air quality stations, overseeing agricultural burning permits, and reviewing air quality–related sections of environmental documents required by CEQA.

The CCAA of 1988 substantially added to the authority and responsibilities of air districts. The CCAA designates air districts as lead air quality planning agencies, requires air districts to prepare air quality plans, and grants air districts authority to implement transportation control measures. The CCAA focuses on attainment of the CAAQS, which, for certain pollutants and averaging periods are more stringent than the comparable Federal standards.

The CCAA requires designation of attainment and non-attainment areas with respect to CAAQS. The CCAA also requires that local and regional air districts expeditiously adopt and prepare an Air Quality Attainment Plan if the district violates state air quality standards for ozone, CO, NO_2, or SO_2. These plans are specifically designed to attain these standards and must be designed to achieve an annual 5% reduction in district-wide emissions of each non-attainment pollutant or its precursors. No locally prepared attainment plans are required for areas that violate the state PM10 standards.

The CCAA requires that the state air quality standards be met as expeditiously as practicable but, unlike the Federal CAA, does not set precise attainment deadlines. Instead, the act established increasingly stringent requirements for areas that would require more time to achieve the standards.

Idling Limit Regulation

CARB has adopted a regulation for in-use off-road diesel vehicles that became effective under California law on June 15, 2008. This regulation is designed to reduce toxic air contaminants (TACs) from diesel-powered construction and mining vehicles operating in California. Fleet owners are subject to retrofit or accelerated replacement/repower requirements for which CARB must obtain authorization from EPA prior to enforcement under the CAA. However, this regulation also imposes idling limitations on owners, operators, and renters or lessees of off-road diesel vehicles, which CARB is authorized to enforce.

The idling limits are effective and enforceable as of June 15, 2008. The regulation requires an operator of applicable off-road vehicles (self-propelled diesel-fueled vehicles of 25 horsepower and greater that were not designed for on-road driving) to limit idling to no more than 5 minutes. These requirements are specified in 13 CCR 2449(d)(3).

Control of Airborne Asbestos

The CARB has adopted an asbestos Airborne Toxic Control Measure (ATCM) for construction, grading, quarrying, and surface mining operations. The measure requires use of best available dust control measures to prevent off-site migration of asbestos-containing dust from road construction and maintenance activities, construction and grading operations, and quarrying and surface mining operations in areas of asbestos, serpentine, or ultramafic rock.

State Tailpipe Emission Standards

To reduce emissions from off-road diesel equipment, on-road diesel trucks, and harbor craft, CARB established a series of increasingly strict emission standards for new engines. New construction equipment used for the program, including heavy duty trucks, off-road construction equipment, tugboats, and barges, will be required to comply with the standards.

State NO_X Reduction Program

The Carl Moyer Memorial Air Quality Standards Attainment Program (Carl Moyer Program) is a voluntary program that offers grants to owners of heavy-duty vehicles and equipment. The program is a partnership between the CARB and the local air districts throughout the state. Locally, the air districts administer the Carl Moyer program. The purpose of the program is to reduce air pollution emissions from heavy-duty engines. Grants are available for projects that:

- install particulate traps,
- replace older heavy-duty engines with newer and cleaner engines and add a particulate trap,
- purchase new vehicles or equipment that is cleaner than the law requires,
- replace heavy-duty equipment with electric equipment, and
- install electric idling-reduction equipment.

3.6.2.1.3 Local

At the local level, responsibilities of air quality districts include overseeing stationary-source emissions, approving permits, maintaining emissions inventories, maintaining air quality stations, overseeing agricultural burning permits, and reviewing air quality-related sections of environmental documents required by CEQA. The air quality districts are also responsible for establishing and enforcing local air quality rules and regulations that address the requirements of Federal and state air quality laws and for ensuring that NAAQS and CAAQS are met.

Yolo-Solano Air Quality Management District

The program construction sites are located in Yolo County; where the Yolo-Solano Air Quality Management District (YSAQMD) has local air quality jurisdiction over the program components. YSAQMD has adopted CEQA emission thresholds in the *Handbook for Assessing and Mitigating Air Quality Impacts* (Yolo-Solano Air Quality Management District 2007) to determine the level of significance of project-related emissions. Table 3.6-2 summarizes applicable thresholds that are used in the analysis of project-related construction and operational emissions. Emissions that exceed the designated threshold levels are considered potentially significant and should be mitigated.

Table 3.6-2. YSAQMD Significance Thresholds for Construction and Operational Emissions

Pollutant	Construction and Operation Significance Threshold
ROG	10 tons/year
NO_X	10 tons/year
PM10	80 lbs/day
CO	Violation of a CAAQA for CO

Source: Yolo-Solano Air Quality Management District 2007.
ROG = reactive organic gas.
NO_X = oxides of nitrogen.
PM10 = particulate matter 10 microns or less in diameter.
CO = carbon monoxide.

All projects located in Yolo County are subject to the YSAQMD regulations in effect at the time of construction. Specific regulations applicable to the proposed program components may involve diesel construction equipment emissions, fugitive dust, on-road haul truck emissions, and general permit requirements. List below are description of YSAQMD rules that would be applicable to the program.

- Dust emissions must be prevented from creating a nuisance to surrounding properties as regulated under Rule 2.5, Nuisance.
- Portable equipment greater than 50 horsepower, other than vehicles, must be registered with either the CARB Portable Equipment Registration Program (PERP) or with the YSAQMD.
- Architectural coating and solvents used at the program shall be compliant with Rule 2.14, Architectural Coatings.

- Cutback and emulsified asphalt application shall be conducted in accordance with Rule 2.28, Cutback and Emulsified Asphalt Paving Materials.

Sacramento Metropolitan Air Quality Management District

The program would generate direct air pollutant emissions from on-site construction equipment in Yolo County; however, the indirect on-road emissions would be generated from delivery trucks and commute vehicles in both Yolo County and Sacramento County. For the indirect on-road emissions that would occur in Sacramento County, the Sacramento Metropolitan Air Quality Management District (SMAQMD) has local air quality jurisdiction over the air pollutant emissions.

SMAQMD has adopted CEQA emission thresholds in the *Guide to Air Quality Assessment* (Sacramento Metropolitan Air Quality Management District 2004) to determine the level of significance of project-related emissions. Table 3.6-3 summarizes applicable thresholds that are used in the analysis for project-related on-road vehicle emissions. Emissions that exceed the designated threshold levels are considered potentially significant and should be mitigated.

Table 3.6-3. SMAQMD Significance Thresholds for Construction and Operational Emissions

Pollutant	Construction Significance Threshold	Operation Significance Threshold
ROG	No threshold	65 lbs/day
NO_X	85 lbs/day	65 lbs/day
PM10	Violation of a CAAQA for PM10	
CO	Violation of a CAAQA for CO	

Source: Sacramento Metropolitan Air Quality Management District 2004.

All construction projects, regardless of size, are required to implement standardized BMPs for fugitive dust control and reduction of tailpipe emissions. If the construction emission exceeds the NO_X threshold, the contractor will be required to provide a plan, for approval by SMAQMD, demonstrating that the heavy-duty off-road equipment to be used in the project sites will achieve a project-wide fleet-average 20% NO_X reduction and 45% diesel particulate reduction compared to the most recent CARB fleet average at time of construction. Because the program would not generate construction emissions from non-road equipment within the SMAQMD, this reduction measure is not applicable. For this program, if the on-road NO_X emissions generated within the SMAQMD exceed the CEQA threshold, the project proponent will be required to pay an offsite mitigation fee of $16,000 per ton of mitigated on-road construction emissions exceeding the NO_X threshold.

3.6.2.2 Climate Change Regulatory Setting

3.6.2.2.1 Federal

Mandatory Greenhouse Gas Reporting Rule

On September 22, 2009, EPA released its final Greenhouse Gas Reporting Rule (Reporting Rule). The Reporting Rule is a response to the fiscal year (FY) 2008 Consolidated Appropriations Act (H.R.

2764; Public Law 110-161), that required EPA to develop "… mandatory reporting of greenhouse gasses above appropriate thresholds in all sectors of the economy…." The Reporting Rule would apply to most entities that emit 25,000 metric tons of carbon dioxide equivalents (CO_2e) or more per year. Starting in 2010, facility owners are required to submit an annual greenhouse gas (GHG) emissions report with detailed calculations of facility GHG emissions. The Reporting Rule would also mandate recordkeeping and administrative requirements in order for EPA to verify annual GHG emissions reports.

Environmental Protection Agency Endangerment and Cause and Contribute Findings

On December 7, 2009, EPA signed the Endangerment and Cause or Contribute Findings for Greenhouse Gases under Section 202(a) of the CAA. Under the Endangerment Finding, EPA finds that the current and projected concentrations of the six key well-mixed GHGs, carbon dioxide (CO2), methane (CH_4), nitrous oxide (N_2O), hydrofluorocarbons, perfluorocarbons, and sulfur hexafluoride in the atmosphere threaten the public health and welfare of current and future generations. Under the Cause or Contribute Finding, EPA finds that the combined emissions of these well-mixed GHGs from new motor vehicles and new motor vehicle engines contribute to the GHG pollution that threatens public health and welfare.

These findings do not themselves impose any requirements on industry or other entities. However, this action is a prerequisite to finalizing the EPA's proposed new Corporate Average Fuel Economy standards for light-duty vehicles, which EPA proposed in a joint proposal including the Department of Transportation's proposed Corporate Average Fuel Economy standards on September 15, 2009.

On February 19, 2010, the CEQ issued draft NEPA guidance on the consideration of the effects of climate change and GHG emissions. This guidance advises Federal agencies that they should consider opportunities to reduce GHG emissions caused by Federal actions, adapt their actions to climate change impacts throughout the NEPA process; and address these issues in their agency NEPA procedures. Where applicable, the scope of the NEPA analysis should cover the GHG emissions effects of a proposed action and alternatives action and the relationship of climate change effects to a proposed action or alternatives.

3.6.2.2.2 State

State Regulations on Greenhouse Gases and Climate Change

Executive Order S-3-05

Signed by Governor Arnold Schwarzenegger on June 1, 2005, Executive Order S-3-05 asserts that California is vulnerable to the effects of climate change. The executive order puts forth that increased temperatures could reduce the Sierra Nevada snowpack, further exacerbate California's air quality problems, and potentially cause a rise in sea levels. To combat those concerns, the executive order established total GHG emissions targets. Executive Order S-3-05 established the following GHG emissions reduction targets for California.

- By 2010, reduce GHG emissions to 2000 levels.
- By 2020, reduce GHG emissions to 1990 levels.
- By 2050, reduce GHG emissions to 80% below 1990 levels.

The executive order directed the secretary of the California Environmental Protection Agency (CalEPA) to initiate a multi-agency effort to reduce GHG emissions to target levels. To comply with the executive order, the secretary of CalEPA created a Climate Act Team (CAT) composed of members of various state agencies and commissions. CAT released its first report in March 2006 (California Environmental Protection Agency 2006). The report proposes achieving GHG targets through the voluntary actions of California businesses, local government and community actions, and state incentive and regulatory programs.

Assembly Bill 32, California Climate Solutions Act of 2006

In September 2006, the California State Legislature adopted Assembly Bill 32, the California Global Warming Solutions Act of 2006 (AB 32). AB 32 establishes a cap on statewide GHG emissions and sets forth the regulatory framework to achieve the corresponding reduction in statewide emission levels. Under AB 32, GHGs are defined as CO_2, methane, NO_X, hydrofluorocarbons, perfluorocarbons, and sulfur hexafluoride. AB 32 requires that CARB takes the following actions.

- Adopt early action measures to reduce GHG.
- Establish a statewide GHG emissions cap for 2020 based on 1990 emissions.
- Adopt mandatory report rules for significant GHG sources.
- Adopt a scoping plan indicating how emission reductions would be achieved through regulations, market mechanisms, and other actions.
- Adopt regulations needed to achieve the maximum technologically feasible and cost-effective reductions in GHGs.

In December 2007, CARB approved the 2020 emission limit (1990 level) of 427 million metric tons of CO_2e. The 2020 target requires the reduction of 169 million metric tons of CO_2e, or approximately 30% below the state's projected "business-as-usual" 2020 emissions of 596 million metric tons of CO_2e.

Also in December 2007, CARB adopted mandatory reporting and verification regulations pursuant to AB 32. The regulations became effective January 1, 2009, with the first reports covering 2008 emissions. The mandatory reporting regulations require reporting for major facilities, those that generate more than 25,000 metric tons/year of CO_2e. To date, CARB has met all of the statutorily mandated deadlines for promulgation and adoption of regulations.

Climate Change Scoping Plan

On December 11, 2008, pursuant to AB 32, CARB adopted the Climate Change Scoping Plan. This plan outlines how emissions reductions from significant sources of GHGs will be achieved via regulations, market mechanisms, and other actions. Six key elements, outlined in the scoping plan, are identified to achieve emissions reduction targets:

- Expanding and strengthening existing energy efficiency programs as well as building and appliance standards.
- Achieving a statewide renewable energy mix of 33%.
- Developing a California cap-and-trade program that links with other Western Climate Initiative partner programs to create a regional market system.

- Establishing targets for transportation-related GHG emissions for regions throughout California, and pursuing policies and incentives to achieve those targets.
- Adopting and implementing measures pursuant to existing state laws and policies, including California's clean car standards, goods movement measures, and the Low Carbon Fuel Standard.
- Creating targeted fees, including a public goods charge on water use, fees on high global warming potential gasses, and a fee to fund the administrative costs of the state's long-term commitment to AB 32 implementation.

The Climate Change Scoping Plan also described recommended measures that were developed to reduce GHG emissions from key sources and activities while improving public health, promoting a cleaner environment, preserving our natural resources, and ensuring that the impacts of the reductions are equitable and do not disproportionately affect low-income and minority communities. These measures put the state on a path to meet the long-term 2050 goal of reducing California's GHG emissions to 80% below 1990 levels. The measures in the approved Climate Change Scoping Plan will be developed over the next 2 years and be in place by 2012.

Senate Bill 97

Senate Bill 97, signed in August 2007, acknowledges that climate change is an important environmental issue that requires analysis under CEQA. The bill directs the California Office of Planning and Research (OPR) to prepare, develop, and transmit to CARB the guidelines for the feasible mitigation of GHG emissions or the effects of GHG emissions, by July 1, 2009. SB 97 directs the State Resources Agency (now Natural Resources Agency), the agency charged with adopting the CEQA Guidelines, to certify and adopt such Guidelines by January 2010.

In June 2008, OPR issued a Technical Advisory on CEQA and Climate Change (California Office of Planning and Research 2008). For projects subject to CEQA, this document recommends that emissions be calculated and mitigation measures be identified to reduce those emissions. The OPR report does not identify emission thresholds for GHGs but instead recommends that each lead agency develop their own thresholds. On December 30, 2009 the Natural Resources Agency adopted amendments to the CEQA Guidelines for Greenhouse gas emission. Those amendments became effective on March 18, 2010. The amendments provide guidance on the analysis and mitigation of the effects of greenhouse gas (GHG) emissions, including determining significance and significance thresholds.

Actions Taken by California Attorney General's Office

The California Attorney General (AG) has filed comment letters under CEQA about a number of proposed projects. The AG also has filed several complaints and obtained settlement agreements for CEQA documents covering general plans and individual programs that the AG found either failed to analyze GHG emissions or failed to provide adequate GHG mitigation. The AG's office prepared a report listing the measures that local agencies should consider under CEQA to offset or reduce global warming effects. The AG's office also has prepared a chart of modeling tools to estimate GHG emissions effects of projects and plans. Information on the AG's actions can be found on the California Department of Justice, Office of Attorney General web site (California Department of Justice 2008).

California Air Pollution Control Officers Association Guidance

The California Air Pollution Control Officers Association (CAPCOA) released a report in January 2008 that describes methods to estimate and mitigate GHG emissions from projects subject to CEQA. The CAPCOA report evaluates several GHG thresholds that could be used to evaluate the significance of a project's GHG emissions. The CAPCOA report, however, does not recommend any one threshold. The report is designed as a resource for public agencies as they establish agency procedures for reviewing GHG emissions from projects subject to CEQA. (California Air Pollution Control Officers Association 2008.)

Executive Order S-13-08

Executive Order S-13-08, issued November 14, 2008, directs the California Natural Resources Agency, Department of Water Resources, Office of Planning and Research, Energy Commission, State Water Resources Control Board, State Parks Department, and California's coastal management agencies to participate in a number of planning and research activities to advance California's ability to adapt to the impacts of climate change. The order specifically directs agencies to work with the National Academy of Sciences to initiate the first California Sea Level Rise Assessment and to review and update the assessment every 2 years after completion; to immediately assess the vulnerability of the California transportation system to sea level rise; and to develop a California Climate Change Adaptation Strategy.

3.6.2.3 Air Quality Environmental Setting

3.6.2.3.1 Regional Climate and Meteorology

The study area is in Yolo County, which is located in the Sacramento Valley Air Basin (SVAB). The SVAB includes Sacramento, Shasta, Tehama, Butte, Glenn, Colusa, Sutter, Yuba, Yolo, and parts of Solano and Placer Counties. The SVAB is bounded on the north by the Cascade Range, on the south by the San Joaquin Valley Air Basin, on the east by the Sierra Nevada, and on the west by the Coast Range.

The SVAB has a Mediterranean climate characterized by hot, dry summers and cool, rainy winters. During winter, the North Pacific storm track intermittently dominates Sacramento Valley weather, and fair weather alternates with periods of extensive clouds and precipitation. Periods of dense and persistent low-level fog, which is most prevalent between storms, are also characteristic of winter weather in the valley. The frequency and persistence of heavy fog in the valley diminishes with the approach of spring. The average yearly temperature range for the Sacramento Valley is 20°F to 115°F, with summer high temperatures often exceeding 90°F and winter low temperatures occasionally dropping below freezing.

In general, the prevailing winds are moderate in strength and vary from moist clean breezes from the south to dry land flows from the north. The mountains surrounding the SVAB create a barrier to airflow, which can trap air pollutants under certain meteorological conditions. The highest frequency of air stagnation occurs in the autumn and early winter when large high-pressure cells collect over the Sacramento Valley. The lack of surface wind during these periods and the reduced vertical flow caused by less surface heating reduces the influx of outside air and allows air pollutants to become concentrated in a stable volume of air. The surface concentrations of pollutants are highest when these conditions are combined with temperature inversions that trap pollutants near the ground.

The ozone season (May through October) in the Sacramento Valley is characterized by stagnant morning air or light winds with the delta sea breeze arriving in the afternoon out of the southwest. Usually the evening breeze transports the airborne pollutants to the north out of the Sacramento Valley. During about half of the days from July to September, however, a phenomenon called the "Schultz Eddy" prevents this from occurring. Instead of allowing for the prevailing wind patterns to move north carrying the pollutants out, the Schultz Eddy causes the wind pattern to circle back to the south. Essentially, this phenomenon causes the air pollutants to be blown south toward the Sacramento Valley and Yolo County. This phenomenon has the effect of exacerbating the pollution levels in the area and increases the likelihood of violating Federal or state standards. The eddy normally dissipates around noon when the delta sea breeze arrives. (Yolo-Solano Air Quality Management District 2007.)

3.6.2.3.2 Background Information on Air Pollutants

Air quality studies generally focus on five pollutants most commonly measured and regulated, and referred to as criteria air pollutants: ozone, CO, inhalable PM (PM10 and PM2.5), NO_2, and SO_2. Because ozone, a photochemical oxidant, is not emitted into the air directly from sources, emissions of ozone precursors, including NO_X and ROG, are regulated with the aim of reducing ozone formation in the lowermost region of the troposphere.

Ozone and NO_2 are considered regional pollutants because they (or their precursors) affect air quality on a regional scale: NO_2 reacts photochemically with ROG to form ozone, and this reaction occurs at some distance downwind of the source of pollutants. Pollutants such as CO, PM10, and PM2.5 are considered to be local pollutants because they tend to disperse rapidly with distance from the source.

The principal characteristics surrounding these pollutants are discussed below. TACs and GHGs are also discussed below, although no air quality standards exist for these pollutants.

Ozone

Ozone is an oxidant that attacks synthetic rubber, textiles, and other materials and causes extensive damage to plants by leaf discoloration and cell damage. It is also a severe eye, nose, and throat irritant and increases susceptibility to respiratory infections. Ozone is not emitted directly into the air: it forms from a photochemical reaction in the atmosphere. Ozone precursors, including ROG and NO_X, are emitted by mobile sources and stationary combustion equipment and react in the presence of sunlight to form ozone. Because reaction rates depend on the intensity of ultraviolet light and air temperature, ozone is primarily a summertime problem.

Carbon Monoxide

CO is essentially inert to most materials and to plants but can significantly affect human health because it combines readily with hemoglobin and thus reduces the amount of oxygen transported in the bloodstream. Effects on humans range from slight headaches to nausea to death. Motor vehicles are the dominant source of CO emissions in most areas. High CO levels develop primarily during winter, when periods of light wind combine with the formation of ground-level temperature inversions—typically from evening through early morning. These conditions result in reduced dispersion of vehicle emissions. Motor vehicles also exhibit increased CO emission rates at low air temperatures.

Particulate Matter

PM suspended in the atmosphere can reduce visibility, retard plant growth, corrode materials, and affect human health. Health concerns focus on particles small enough to reach the lungs when inhaled (inhalable PM). NAAQS and CAAQS for PM apply to two classes of inhalable particulates: PM10 and PM2.5.

Nitrogen Dioxide

NO_2 is a brownish gas that contributes to the formation of ground-level ozone pollution. NO_2 increases respiratory disease and irritation and may reduce resistance to certain infections. The majority of ambient NO_2 is not directly emitted but is formed rather quickly from the reaction of nitric oxide (NO) and oxygen in the atmosphere. NO and NO_2 are the primary pollutants that make up the group of pollutants referred to as NO_X. In the presence of sunlight, complex reactions of NO_X with ozone and other air pollutants produce the majority of NO_2 in the atmosphere. NO_2 is one of the NO_X emitted from high-temperature combustion processes, such as those occurring in trucks, cars, and power plants. Indoors, home heaters and gas stoves also produce substantial amounts of NO_2.

Sulfur Dioxide

SO_2 is a colorless, irritating gas with a "rotten egg" smell formed primarily by the combustion of sulfur-containing fossil fuels. SO_2 is formed when sulfur-containing fuel is burned by mobile sources, such as locomotives and off-road diesel equipment. SO_2 also is emitted from several industrial processes, such as petroleum refining and metal processing.

Toxic Air Contaminants

TACs are a category of air pollutants that have been shown to affect human health but are not classified as criteria pollutants. TACs are generated by various kinds of sources, including stationary sources such as dry cleaners and gas stations; combustion sources; mobile sources such as diesel trucks, ships, and trains; and area sources such as farms, landfills, and construction sites. Significant health effects of TACs can be carcinogenic (cancer-causing), short-term (acute) non-carcinogenic, and long-term (chronic) non-carcinogenic. To date, CARB has identified 21 TACs and adopted EPA's list of hazardous air pollutants (HAPs) as TACs. In August 1998, diesel particulate matter (DPM) was added to the CARB list of TACs (California Air Resources Board 1998).

Diesel Particulate Matter

DPM is the most complex of diesel emissions. Diesel particulates, as defined by most emission standards, result from diluted and cooled exhaust gasses. DPM in California is a significant part of the total TAC level in the state. In September 2000, CARB approved a Diesel Risk Reduction Plan (California Air Resources Board 2000) to reduce PM emissions from diesel-fueled engines and vehicles. The plan outlines a comprehensive and ambitious program to reduce emissions from new and existing on-road vehicles (e.g., heavy-duty trucks and buses); off-road equipment (e.g., graders, tractors, forklifts, sweepers, and boats); portable equipment (e.g., pumps); and stationary engines (e.g., stand-by power generators). According to the plan, CARB will work with the heavy-duty equipment manufacturing companies and operators to develop an emissions reduction program for construction equipment.

3.6.2.3.3 Existing Air Quality Conditions

Air quality monitoring data for the last 3 years (2006–2008) are presented in Table 3.6-3. Although the program is located in Yolo County, the nearest monitoring stations in both Yolo County and Sacramento County are selected to present air quality of program vicinity. Air quality concentrations typically are expressed in terms of ppm or micrograms per cubic meter ($\mu g/m^3$). The nearest monitoring stations to the study area are the West Sacramento 15th Street station, which monitors PM10, the Sacramento T Street station, which monitors ozone and PM2.5; and the Sacramento Del Paso Manor station, which monitors CO.

As indicated in Table 3.6-4, the 15th Street monitoring station has experienced 19 violations of the state 24-hour PM10 standard during the last 3 years. The T Street monitoring station has experienced 15 violations of the state 1-hour ozone standard and 39 violations of the state 8-hour ozone standard. There were 37 violations of the Federal 24-hour PM2.5 standard at the T Street monitoring station. There were no violations of the CO standards during this period.

Table 3.6-4. Ambient Air Quality Monitoring Data from the West Sacramento and Sacramento Stations (2006–2008)

Pollutant Standard	2006	2007	2008
Ozone—Sacramento T Street Station			
National maximum 1-hour concentration (ppm)	0.106	0.109	0.107
National maximum 8-hour concentration (ppm)	0.090	0.089	0.092
Number of days standard exceeded [a]			
CAAQS 1-hour (>0.09 ppm)	6	2	7
NAAQS 8-hour (>0.075 ppm)	6	2	9
CAAQS 8-hour (>0.07 ppm)	14	7	18
CO—Sacramento Del Paso Manor Station			
National maximum 8-hour concentration (ppm)	3.5	2.9	2.5
National maximum 1-hour concentration (ppm)	4.4	3.5	2.9
Number of days standard exceeded [a]			
NAAQS 8-hour (≥9.0 ppm)	0	0	0
CAAQS 8-hour (≥9.0 ppm)	0	0	0
NAAQS 1-hour (≥35 ppm)	0	0	0
PM10[b]—West Sacramento 15th Street Station			
National maximum 24-hour concentration (μg/m^3) [c]	77	61	61
State maximum 24-hour concentration (μg/m^3) [d]	78.0	66.0	61.6
National annual average concentration (μg/m^3)	28	21	29
State annual average concentration (μg/m^3) [e]	28.8	21.7	–
Number of days standard exceeded [a]			
NAAQS 24-hour (>150 μg/m^3) [f]	0	0	0
CAAQS 24-hour (>50 μg/m^3) [f]	9	5	5
PM2.5[b]— Sacramento T Street Station			
National maximum 24-hour concentration (μg/m^3) [c]	54.0	58.0	66.1
State maximum 24-hour concentration (μg/m^3) [d]	54.0	58.0	78.9
National annual average concentration (μg/m^3)	12.4	11.9	9.8
State annual average concentration (μg/m^3) [e]	12.9	–	–
Number of days standard exceeded [a]			
NAAQS 24-hour (>35 μg/m^3) [f]	14	19	4

Sources: California Air Resources Board 2009b, U.S. Environmental Protection Agency 2009a.

– = insufficient data available to determine the value.

[a] An exceedance is not necessarily a violation.

[b] Measurements usually are collected every 6 days.

[c] National statistics are based on standard conditions data. In addition, national statistics are based on samplers using Federal reference or equivalent methods.

[d] State statistics are based on local conditions data, except in the South Coast Air Basin, for which statistics are based on standard conditions data. In addition, state statistics are based on California-approved samplers.

[e] State criteria for ensuring that data are sufficiently complete for calculating valid annual averages are more stringent than the national criteria.

[f] Mathematical estimate of how many days concentrations would have been measured as higher than the level of the standard had each day been monitored.

3.6.2.3.4 Air Quality Attainment Status

The air quality attainment status for criteria pollutants in Yolo County and Sacramento County are summarized in Table 3.6-5. Areas are classified as in attainment or in non-attainment with respect to CAAQS and NAAQS. These classifications are made by comparing actual monitored air pollutant concentrations to state and Federal standards. If a pollutant concentration is lower than the state or Federal standard, the area is considered to be in attainment of the standard for that pollutant. If pollutant levels exceed a standard, the area is considered a non-attainment area. If data are insufficient to determine whether a pollutant is violating the standard, the area is designated as unclassified. This typically occurs in non-urbanized areas, where pollutant levels may be less closely monitored.

On December 22, 2008, EPA classified Yolo County as a partial non-attainment area for the PM2.5 standard. With the new designation, an attainment plan will be submitted to EPA by 2012.

Table 3.6-5. Yolo County and Sacramento County Air Quality Attainment Status

Pollutant	Averaging Time	State Standards	National Standards
Yolo County			
Ozone	1-Hour	Serious Non-attainment	No Designation
	8-Hour	Non-attainment	Serious Non-attainment
CO		Attainment	Attainment
PM10	24-Hour	Non-attainment	Unclassified
PM2.5	24-Hour	Unclassified	Partial Non-attainment
Sacramento County			
Ozone	1-Hour	Serious Non-attainment	No Designation
	8-Hour	Non-attainment	Serious Non-attainment
CO		Attainment	Attainment
PM10	24-Hour	Non-attainment	Moderate Non-attainment
PM2.5	24-Hour	Non-attainment	Unclassified/Attainment

Source: California Air Resources Board 2009c.

3.6.2.3.5 Sensitive Receptors

The NAAQS and CAAQS apply at publicly accessible areas, regardless of whether those areas are populated. For the purposes of air quality analysis, sensitive land uses are defined as locations where human populations, especially children, seniors, and sick persons, are located and where there is reasonable expectation of continuous human exposure according to the averaging period for the air quality standards (e.g., 24-hour, 8-hour, and 1-hour). Typical sensitive receptors are residences, hospitals, and schools.

Sensitive land uses adjacent to the construction area are primarily residential subdivisions and isolated single-family residences. Other sensitive land uses include schools (e.g., Bryte Elementary), hospitals (e.g., Sutter General), and areas of recreation (e.g., the Jedediah Smith Recreational Trail).

Sensitive receptors that could be affected by the direct and indirect emissions associated with the project construction include receptors in the City of Sacramento across the river from program

construction sites and receptors adjacent to the construction zones and haul routes in both Yolo County and Sacramento County.

3.6.2.4 Climate Change Environmental Setting

3.6.2.4.1 Background Information on Climate Change

Global warming refers to the increase in the average temperature of the Earth's near-surface air and oceans since the mid-20th century and its projected continuation. Warming of the climate system is now considered to by unequivocal (Intergovernmental Panel on Climate Change 2007) with global surface temperature increasing approximately 1.33°F over the last 100 years. Continued warming is projected to increase the average global temperature between 2°F and 11°F over the next 100 years. The causes of this warming have been identified as both natural processes and as the result of human actions. The Intergovernmental Panel on Climate Change (IPCC) concludes that variations in natural phenomena such as solar radiation and volcanoes produced most of the warming from pre-industrial times to 1950 and had a small cooling effect afterward. However, after 1950, increasing GHG concentrations resulting from human activity such as fossil fuel burning and deforestation have been responsible for most of the observed temperature increase.

Increases in GHG concentrations in the Earth's atmosphere are thought to be the main cause of human-induced climate change. GHGs naturally trap heat by impeding the exit of solar radiation that has hit the Earth and is reflected back into space. Some GHGs occur naturally and are necessary for keeping the Earth's surface inhabitable. However, increases in the concentrations of these gasses in the atmosphere during the last 100 years have decreased the amount of solar radiation that is reflected back into space, intensifying the natural greenhouse effect and resulting in the increase of global average temperature.

The principal GHGs are carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), sulfur hexafluoride (SF_6), perfluorocarbons, hydrofluorocarbons, and water vapor. Each of the principal greenhouse gasses has a long atmospheric lifetime (1 year to several thousand years). In addition, the potential heat trapping ability of each of these gasses varies significantly. Methane is 23 times as potent as CO_2, while SF_6 is 22,200 times more potent than CO_2. The most common GHG is CO_2, which constitutes approximately 84% of all emissions of GHGs in California. GHGs are global pollutants, unlike criteria air pollutants (such as ozone precursors) and TACs, which are pollutants of regional and local concern.

Conventionally, GHGs have been reported as CO_{2e}, an equivalency measure that takes into account the relative potency of non-CO_2 GHGs and converts their quantities to an equivalent amount of CO_2 so that all emissions can be reported as a single quantity. The primary human-made processes that release these gasses include burning of fossil fuels for transportation, heating and electricity generation; agricultural practices that release methane such as livestock grazing and crop residue decomposition; and industrial processes that release smaller amounts of high global warming potential gasses such as SF_6, perfluorocarbons, and hydrofluorocarbons. Deforestation and land cover conversion have also been identified as contributing to global warming by reducing the Earth's capacity to remove CO_2 from the air and altering the Earth's albedo or surface reflectance, allowing more solar radiation to be absorbed.

3.6.2.4.2 Global Climate Trends and Associated Impacts

The rate of increase in global average surface temperature over the last 100 years has not been consistent; the last three decades have warmed at a much faster rate – on average 0.32°F per decade. Eleven of the twelve years from 1995 to 2006 rank among the twelve warmest years in the instrumental record of global average surface temperature (going back to 1850) (Intergovernmental Panel on Climate Change 2007).

During the same period over which this increased global warming has occurred, many other changes have occurred in other natural systems. Sea levels have risen on average1.8 millimeters per year; precipitation patterns throughout the world have shifted, with some areas becoming wetter and others drier; tropical cyclone activity in the North Atlantic has increased; peak runoff timing of many glacial and snow-fed rivers has shifted earlier; as well as numerous other observed conditions. Although it is difficult to prove a definitive cause and effect relationship between global warming and other observed changes to natural systems, there is high confidence in the scientific community that these changes are a direct result of increased global temperatures (Intergovernmental Panel on Climate Change2007).

3.6.2.4.3 California Climate Trends

Maximum (daytime) and minimum (nighttime) temperatures are increasing almost everywhere in California but at different rates. The annual *minimum* temperature averaged over all of California increased 0.33°F per decade from 1920 to 2003, while the average annual *maximum* temperature increased 0.1°F per decade (Moser et al. 2009).

With respect to California's water resources, the most significant impacts of global warming have been changes to the water cycle and sea level rise. Over the past century, the precipitation mix between snow and rain has shifted in favor of more rainfall and less snow (Mote et al. 2005, Knowles 2006) and snow pack in the Sierra Nevada is melting earlier in the spring (Kapnick and Hall 2009). The average early spring snowpack in the Sierra Nevada has decreased by about 10% during the last century, a loss of 1.5 million acre-feet of snowpack storage (California Department of Water Resources 2008). These changes have significant implications for water supply, flooding, aquatic ecosystems, energy generation, and recreation throughout the state. During the same period, sea levels along California's coast rose 7 inches (California Department of Water Resources 2008). Sea level rise associated with global warming will continue to threaten coastal lands and infrastructure, increase flooding at the mouths of rivers, place additional stress on levees in the Sacramento-San Joaquin Delta, and will intensify the difficulty of managing the Sacramento-San Joaquin Delta as the heart of the state's water supply system.

3.6.2.4.4 Local Climate

See Section 3.6.2.3.1, Regional Climate and Meteorology, above.

3.6.3 Environmental Consequences

This section describes the air quality and climate change effects associated with the program. It describes the methods used to determine the effects of the program and lists the thresholds used to conclude whether an effect would be significant. Measures to mitigate (i.e., avoid, minimize, reduce,

eliminate, or compensate for) significant effects accompany each effect discussion. Air quality and climate change environmental consequences have been divided into individual sections for ease of review.

3.6.3.1 Air Quality Assessment Methods

Almost all increased air pollutant emissions associated with the proposed program would be generated by construction-related activities. Therefore, the focus of the air quality analysis is to evaluate whether the construction-related emissions would exceed emission thresholds as established by YSAQMD, SMAQMD, and General Conformity thresholds. Construction emissions from the program implementation would result in localized, short-term effects on ambient air quality in the area. These short-term emissions, especially PM10, ROG, and NO_X, have the potential to represent a significant air quality effect. Fugitive dust emissions are associated primarily with site preparation, excavation, and levee reconstruction earthwork, and vary as a function of factors such as soil silt content, soil moisture, wind speed, acreage of disturbance area, and vehicle miles traveled on site and off site. For the construction of the program, ROG and NO_X emissions are associated primarily with diesel equipment exhaust and asphalt paving.

After the proposed alternatives are constructed, maintenance of the program facilities generally would be performed as needed. Maintenance work is less extensive than the construction activities and takes place over a few days per year. In addition, maintenance and operational activities are part of the existing environmental baseline and thus would not create a substantial source of new emissions.

There are nine levee reaches within the study area. Depending on the deficiencies, a number of alternatives or combination of alternatives can be constructed to address the deficiencies along each reach. For the purposes of the air quality analysis, levee alternatives that would be constructed in the same time under the same project should be evaluated together, which could include alternatives that occur at multiple locations or along multiple reaches, depending on the scale of a project. At this time, the actual project locations, construction schedule, proposed alternatives, and the magnitude of the construction have not been determined for the program. Therefore, the air quality effect of the program implementation is evaluated qualitatively. Program-level mitigation measures are recommended, and a more in-depth analysis of potential air quality effects would be performed in a separate project-level document when a project is identified.

To assist in the determination of effects, various quantitative models are available to predict emissions and particulate matter generation. Two such models are URBEMIS and SacRCEM. While SacRCEM has typically been used for other recent levee improvement projects in the Sacramento Valley, both models have been applied to simulate the project-level air quality effects of the WSLIP. Given the similarity in the architecture of the two models, for ROG, NO_X, and CO_2, the outputs from the two models are very similar and any variance is considered not statistically significant. For PM, the URBEMIS outputs are considered more conservative (meaning the production values are higher) based on the model's internal methods and assumptions for treatment of earthwork. As the project proponent, WSAFCA has selected this more conservative approach to not under-predict potential project effects. URBEMIS further allows application of mitigation measures to fine-tune and predict quantitative effectiveness of available measures and assist in determining post-mitigation findings. For these reasons, WSAFCA has selected to use the results of URBEMIS for quantitative determination of effects, effect findings, and mitigation efficacy. The results of both models for the WSLIP EIPs are in Appendix E.

3.6.3.2 Air Quality Determination of Effects

For this analysis, an effect pertaining to air quality was analyzed based on professional practice, and State CEQA Guidelines Appendix G (14 CCR 15000 *et seq*.). An effect was considered significant if it would:

- conflict with, or obstruct implementation of, the applicable air quality plan;
- violate any air quality standard or substantial contribution to existing or projected air quality violation;
- result in a cumulatively considerable net increase of any criteria pollutant for which the project region is a non-attainment area under NAAQS and CAAQS;
- expose sensitive receptors to substantial pollutant concentrations;
- create objectionable odors affecting a substantial number of people;

The appropriate district-recommended emission thresholds as published in their respective CEQA guidance documents also apply to individual projects under their jurisdiction. For portions of the construction and operational activities that would occur in Yolo County, an air quality effect is considered to be significant if the air pollutant emissions would exceed YSAQMD's thresholds of significance as shown in Table 3.6-2. For portions of the construction activities that would occur within USACE's jurisdiction, an air quality effect is considered to be significant if the air pollutant emissions exceed the General Conformity thresholds.

3.6.3.3 Air Quality Effects and Mitigation Measures

3.6.3.3.1 No Action Alternative

To recap from Chapter 2, Alternatives, the No Action Alternative is the continuation of the existing deficiencies along the nine levee reaches and absence of levee alternatives to increase the level of protection. Current levee operations and maintenance activities would continue, but there would be no construction-related emissions from program implementation or maintenance.

Without improvements to the levee system, the risk of levee failure would remain high. Under these conditions, any of the levee deficiencies could cause portions of the levees to fail, triggering widespread flooding and extensive damage. If a catastrophic flood were to occur, emergency flood fighting and clean-up actions would require the use of a considerable amount of heavy construction equipment. Timing and duration of use would directly correlate with flood fighting needs, but it is likely that pollutants emitted would violate air quality standards for pollutants (including those for which the area is already considered non-attainment), increase GHG emissions, and expose sensitive receptors to toxic air emissions. Depending on the magnitude of the flood, flood fighting could last for weeks or even months. Furthermore, because of the unpredictable nature of an emergency response, no BMPs to manage emissions would be in place. All of these effects could be considered significant. However, the timing, duration, and magnitude of a flood event are speculative and unpredictable, and therefore a precise determination of significance is not possible. A discussion of the potential exposure to ruptured gas lines and utilities is provided in Section 3.17, Public Health and Hazards.

3.6.3.3.2 Flood and Recreation Program Alternatives

Effect AQ-1: Conflict with or Obstruct an Applicable Air Quality Plan

A program or project is deemed inconsistent with an air quality plan if it would result in population or employment growth that exceeds the growth estimates in the applicable air quality plan—thus generating emissions not accounted for in the applicable air quality plan emissions budget. Consequently, proposed programs need to be evaluated to determine whether they would generate population and employment growth and, if so, whether that growth would exceed the growth rate included in the relevant air quality plan.

As described in Chapter 6, Growth-Inducing and Cumulative Effects, the implementation of the program might remove an obstacle for undeveloped lands in West Sacramento and make development easier or more attractive for these lands, which might result in population growth in these areas in the long term. The City is currently in the process of updating its 1994 General Plan. It is expected that the new General Plan will include the land use changes in these areas. Additionally, the 2035 Metropolitan Transportation Plan (Sacramento Area Council of Government 2008) has included the population projection of 278,786 people for Yolo County and 87,402 people for West Sacramento, which has accounted for the land development and population growth of these areas through 2035. The air quality conformity analysis as part of the 2035 Metropolitan Transportation Plan meets the emission conformity test for the Sacramento ozone non-attainment area. Therefore, the program would not conflict with or obstruct the implementation of air quality plans. This effect would be less than significant. No mitigation is required.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall	▪ Seepage berm
	▪ Levee raise (in place)	▪ Sheet pile wall
	▪ Levee raise (adjacent)	▪ Slurry cutoff wall
	▪ Levee raise (full)	▪ Slope flattening
	▪ Closure structure	▪ Stability berm
	▪ Interior drain	▪ Rock slope protection
	▪ Jet grouting	▪ Setback levee
	▪ Relief wells	▪ Vegetation removal
Recreation	▪ Trails	▪ Developed water access
	▪ Riverside parks	▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect would occur in all nine program reaches.

Effect AQ-1 Finding	With Mitigation
Less than significant	N/A

Effect AQ-2: Increase in Construction Emissions to Exceed Applicable Thresholds

Construction activities associated with proposed alternatives of the program would result in the temporary generation of ROG, NO_X, CO, PM2.5 and PM10 emissions from excavation, vegetation clearing, grading, cut-fill, motor vehicle exhaust associated with construction equipment, construction employee commute trips, material transport (especially on unpaved surfaces), and other construction activities.

Construction emissions generated from the construction sites and on-road vehicles traveling within Yolo County are subject to YSAQMD CEQA thresholds (as shown in Table 3.6-2); and construction emissions generated from on-road vehicles traveling within Sacramento County are subject to SMAQMD CEQA thresholds (as shown in Table 3.6-3). All construction emissions generated by the program components are subject to the General Conformity thresholds because USACE has jurisdiction over the entire program.

Depending on the actual project locations, construction schedule, proposed alternatives, and the magnitude of the construction, unmitigated construction emissions could potentially exceed the YSAQMD CEQA thresholds (as shown in Table 3.6-2). Unmitigated NO_X emissions, in particular, often exceed district thresholds when multiple pieces of construction equipment are operated simultaneously, and fugitive dust emissions (PM10 and PM2.5) can be high when large quantities of soil are excavated, transported, and placed. A more in-depth analysis of potential air quality effects should be performed to calculate construction emissions when a project is identified. If the unmitigated construction emissions exceed the YSAQMD CEQA thresholds (e.g., NO_X, ROG, and PM10) or General Conformity thresholds (e.g., NO_X, ROG, PM10, and PM2.5), Mitigation Measures AQ-MM-1 to AQ-MM-3 should be implemented.

Construction emissions generated from on-road vehicles traveling within Sacramento County are unlikely to exceed the SMAQMD NO_X threshold, if only a single levee project is conducted on any given day. However, it is theoretically possible to exceed the threshold if several program components are constructed on the same day. If the on-road construction emissions generated by multiple, simultaneous projects exceed the NO_X threshold, Mitigation Measure AQ-MM-4 should be implemented.

The unmitigated construction emissions (NO_X, ROG, PM10, and PM2.5) are less likely to exceed the General Conformity applicability thresholds. As analyzed in Chapters 4 and 5 for the two currently proposed EIPs, the mitigated construction emissions would be well below the thresholds. However, if the mitigated construction emissions from multiple, simultaneous project elements exceed these applicability thresholds then WSAFCA must conduct the consultation with the YSAQMD as required by the General Conformity Regulation. Any offset resulting from the implementation of Mitigation Measure AQ-MM-4 would not be considered for the General Conformity analysis.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall ▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Closure structure ▪ Interior drain ▪ Jet grouting ▪ Relief wells	▪ Seepage berm ▪ Sheet pile wall ▪ Slurry cutoff wall ▪ Slope flattening ▪ Stability berm ▪ Rock slope protection ▪ Setback levee ▪ Vegetation removal
Recreation	▪ Trails ▪ Riverside parks ▪ Developed water access ▪ Special projects	

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect would occur in all nine program reaches.

Effect AQ-2 Finding	With Mitigation
Significant	Potentially significant and unavoidable

Mitigation Measures

Mitigation Measure AQ-MM-1: Implement Measures to Reduce Exhaust Emissions of NO_X and ROG if Unmitigated Emissions Exceed NO_X and ROG Thresholds

Unmitigated NO_X and ROG emissions from construction equipment tailpipes could potentially exceed the YSAQMD CEQA thresholds. Therefore, WSAFCA will require the construction contractor to implement feasible and reasonable measures to reduce public nuisance and tailpipe emissions from diesel-powered construction equipment. This requirement will be incorporated into the construction contracts.

Depending on the exceedance amounts of NO_X and ROG emissions, the WSAFCA will require the construction contractor to implement either or both of the following mitigation options.

Mitigation Measure AQ-MM-1a

According to the YSAQMD guideline (Yolo-Solano Air Quality Management District 2007), the project lead agency is encouraged to explore and incorporate mitigation measures as technology advances and less emissive products become available at lower costs.

The measures recommended by the YSAQMD are listed below.

- Reduce use, trips, and unnecessary idling of heavy equipment. Shut down idling equipment that is not used for more than 5 consecutive minutes as required by California law.
- Maintain all construction equipment in proper tune according to manufacturer's specifications.
- Use a modern equipment fleet meeting CARB's 1996 or newer certification standard for off-road heavy-duty diesel engines.
- Install emission control devices on older equipment to reduce CO, ROG, and NO_X emissions to levels equivalent to CARB's 1996 or newer certification standard.
- Locate stationary diesel-powered equipment and haul truck staging areas as far as practicable from sensitive receptors.
- Use existing power sources (e.g., power lines) or clean fuel generators rather than conventional diesel generators, when feasible
- Substitute gasoline-powered for diesel-powered equipment when feasible.
- Use reformulated and emulsified diesel fuels where feasible.
- Use alternatively fueled construction equipment on site where feasible, such as compressed natural gas (CNG), liquefied natural gas (LNG), propane, or biodiesel.
- Use aqueous diesel fuel where feasible.
- Use CARB and/or EPA-verified particulate traps and other appropriate controls (i.e. diesel oxidation catalyst or diesel particular filters) where feasible to reduce emissions of NO_X, diesel particulate, and other pollutants at the construction site.

Mitigation Measure AQ-MM-1b

In addition to above measures, the construction contractor could provide a plan, for approval by WSAFCA and YSAQMD, demonstrating that the heavy-duty off-road equipment to be used at the project sites, including owned, leased, and subcontractor equipment, will achieve a project-wide fleet-average reduction of 20% for NO_X and 45% for diesel particulate, compared to the most recent CARB fleet average at time of construction. A construction mitigation calculator may be downloaded from the SMAQMD web site to perform the fleet average evaluation (Sacramento Metropolitan Air Quality Management District 2009).

However, with the implementation of above mitigations, NO_X and ROG emissions from the construction of a project still might exceed YSAQMD thresholds, depending on the size of a proposed project and specific measures chosen to reduce the construction emissions.

Mitigation Measure AQ-MM-2: Implement Fugitive Dust Control Plan if Unmitigated Emissions Exceed PM10 or PM2.5 Thresholds

Uncontrolled fugitive dust emissions for the construction of the program could exceed the General Conformity threshold of 100 tons/year for PM 10 and PM2.5 and the YSAQMD's 80 pounds/day threshold for PM 10 and could cause ambient concentrations of PM 10 and PM2.5 to approach CAAQS and NAAQS limits. Therefore, fugitive dust emissions are considered a significant effect. The construction contractor will implement all applicable and feasible fugitive dust control measures

required by YSAQMD including those listed below. This requirement will be incorporated into the construction contract.

- Post a publicly visible sign with the telephone number and person to contact regarding dust complaints. This person would respond and take corrective action within 48 hours. The phone number of YSAQMD also will be visible to ensure compliance with the YSAQMD Rule 2.5, Nuisance.
- Water active unpaved areas at all construction sites at least twice daily in dry conditions, with the frequency of watering based on the type of operation, soil, and wind exposure.
- Prohibit all grading activities and water all areas of disturbed soil under windy conditions (more than 20 miles per hour).
- Limit on-site vehicles to a speed that prevents visible dust emissions to extend beyond unpaved roads.
- Cover all trucks hauling dirt, sand, or loose materials.
- Cover active and inactive storage piles where appropriate.
- Cover or hydroseed unpaved areas that will remain inactive for extended periods.
- Apply soil stabilizers to active and inactive areas where appropriate.
- Install wheel washers at the entrance to construction sites for all exiting trucks.
- Sweep streets if visible soil material is carried out from the construction site.
- Install wind fencing and phase-grading operations where appropriate.

Fugitive dust emissions from the construction of a project would be reduced to a less-than-significant level with the implementation of above mitigation.

As described in the General Conformity regulation, the mitigated fugitive dust emissions (PM 10 and PM2.5) are required to meet the General Conformity applicability thresholds, which would also be reduce to a less-than-significant level with the implementation of above mitigation.

Mitigation Measure AQ-MM-3: Provide Advance Notification of Construction Schedule and 24-Hour Hotline to Residents

The program proponent will provide advance written notification of the proposed construction activities to all residences and other air quality-sensitive uses within 500 feet of the construction site. Notification will include a brief overview of the proposed project and its purpose, as well as the proposed construction activities and schedule. It will also include the name and contact information of the program proponent's project manager or a representative for ensuring that reasonable measures are implemented to address the problem.

Mitigation Measure AQ-MM-4: Pay Required Fees to the SMAQMD to Offset NO_X Emissions

It is possible that on-road construction emissions, for vehicles traveling within the Sacramento County, could exceed the SMAQMD NO_X threshold. If on-road construction emissions exceed SMAQMD threshold levels, the project proponent will be required to pay an offsite mitigation fee. Prior to the approval of project plans or the issuance of grading permits, the project proponent will submit proof that the offsite air quality mitigation fee of $16,000 per ton of NO_X has been paid to SMAQMD and that the construction air quality mitigation plan has been approved by SMAQMD and

the lead agency. SMAQMD already has enacted a well-defined program to use NO_X offset fees received from applicants to fund regional NO_X emission reduction projects. Therefore, with the implementation of this mitigation, the air quality impact to SMAQMD would be reduced to a less-than-significant level.

Effect AQ-3: Long-Term Operation and Maintenance Emissions of ROG, NO_X, and PM10

After the proposed alternatives are constructed, the program facilities will be generally maintained as needed. Maintenance work would be less extensive and would take place over a few days per year. In addition, maintenance and operational activities are part of the existing environmental baseline and thus would not create a substantial source of new emissions. This effect would be less than significant. No mitigation is required.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall	▪ Seepage berm
	▪ Levee raise (in place)	▪ Sheet pile wall
	▪ Levee raise (adjacent)	▪ Slurry cutoff wall
	▪ Levee raise (full)	▪ Slope flattening
	▪ Closure structure	▪ Stability berm
	▪ Interior drain	▪ Rock slope protection
	▪ Jet grouting	▪ Setback levee
	▪ Relief wells	▪ Vegetation removal
Recreation	▪ Trails	▪ Developed water access
	▪ Riverside parks	▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect would occur in all nine program reaches.

Effect AQ-3 Finding	With Mitigation
Less than significant	N/A

Effect AQ-4: Exposure of Sensitive Receptors to Toxic Air Emissions

Construction of the proposed alternatives would result in short-term diesel exhaust emissions from on-site heavy duty equipment. Diesel particulate matter (DPM) emissions from diesel-fueled engines (DPM) were identified as a TAC by CARB in 1998. Construction of alternatives would result in the generation of DPM emissions from the use of off-road diesel equipment required for site grading and excavation, paving, and other construction activities.

The assessment of health risks associated with exposure to diesel exhaust typically is associated with chronic exposure, in which a 70-year exposure period is often assumed. However, while cancer can result from exposure periods of less than 70 years, acute exposure periods (i.e., exposure periods of 2 to 3 years) to diesel exhaust are not anticipated to result in an increased health risk, as health risks associated with exposure to diesel exhaust are typically seen in exposures periods that are chronic. Construction of the program is not expected to take place at the same construction site for more than 1 to 2 years and would be expected to use a limited number of pieces of heavy equipment at the same construction site. Although DPM emissions are not anticipated to result in an increased health risk, these emissions may still have an adverse effect on those people living near the construction site that have asthma and chronic bronchitis.

However, as required by CARB regulation, no in-use off-road diesel vehicles may idle for more than 5 consecutive minutes. In addition, implementation of Mitigation Measure AQ-MM-1 would further reduce exhaust emissions during construction and implementation of Mitigation Measure AQ-MM-3 would ensure the implementation of reasonable measures to address residents' health concerns related to construction emissions. With implementation of mitigation measures and best management practices, the effect would be reduced to less than significant and no further mitigation is required.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall	▪ Seepage berm
	▪ Levee raise (in place)	▪ Sheet pile wall
	▪ Levee raise (adjacent)	▪ Slurry cutoff wall
	▪ Levee raise (full)	▪ Slope flattening
	▪ Closure structure	▪ Stability berm
	▪ Interior drain	▪ Rock slope protection
	▪ Jet grouting	▪ Setback levee
	▪ Relief wells	▪ Vegetation removal
Recreation	▪ Trails	▪ Developed water access
	▪ Riverside parks	▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect could occur in all nine program reaches, depending on the location of sensitive receptors.

Effect AQ-4 Finding	With Mitigation
Less than significant	N/A

Effect AQ-5: Exposure to Objectionable Odors from Diesel Exhaust

The program implementation would not result in any major sources of odor, and the program would not involve operation of any of the common types of facilities that are known to produce odors (e.g.,

landfill, wastewater treatment facility). In addition, odors associated with diesel exhaust from the use of on-site construction equipment would be intermittent and temporary and would dissipate rapidly from the source with an increase in distance.

Furthermore, as required by CARB regulation, no in-use off-road diesel vehicles may idle for more than 5 consecutive minutes. Implementation of Mitigation Measures AQ-MM-1 and AQ-MM-3 would further reduce exhaust emissions during construction. This effect would be less than significant. No mitigation is required.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall ▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Closure structure ▪ Interior drain ▪ Jet grouting ▪ Relief wells	▪ Seepage berm ▪ Sheet pile wall ▪ Slurry cutoff wall ▪ Slope flattening ▪ Stability berm ▪ Rock slope protection ▪ Setback levee ▪ Vegetation removal
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect would occur in all nine program reaches.

Effect AQ-5 Finding	With Mitigation
Less than significant	N/A

3.6.3.4 Climate Change Assessment Methods

Almost all increased GHG emissions associated with the proposed program would be generated by construction-related activities. Therefore, the focus of the GHG analysis is to evaluate construction-related emissions. The principal source of GHG emissions associated with program implementation would be temporary tailpipe emissions from construction equipment and haul trucks; the principal GHG produced would be CO_2. No air district in California, including YSAQMD, has formally adopted a significant threshold for analyzing GHG or CO_2 emissions generated by a proposed project, or a methodology for analyzing air quality effects related to global warming. However, CARB and the major air quality agencies in the state (Bay Area Air Quality Management District [BAAQMD], South Coast Air Quality Management District [SCAQMD] and San Joaquin Valley Air Pollution Control District [SJVAPCD]) have published draft thresholds for defining the significance of GHG emissions from construction projects and operational projects. Those draft thresholds and mitigation measures were used in the analysis of effects related to climate change.

There are nine levee reaches in the study area. Depending on the deficiencies, a number of alternatives or combination of alternatives can be constructed to address the deficiencies along each reach. For the purposes of the climate change analysis, levee alternatives that would be constructed in the same time under the same project should be evaluated together, which could include alternatives that occur at multiple locations or along multiple reaches, depending on the scale of a project. At this time, the actual project locations, construction schedule, proposed alternatives, and the magnitude of the construction have not been determined for the program. Therefore, to assess the significance of the forecast program-wide GHG emissions, the emission estimates for two currently-proposed EIPs were considered, and then extrapolated to estimate the program-wide GHG emissions.

To assist in the determination of effects, various quantitative models are available to predict emissions; URBEMIS and SacREM. As described in Section 3.6.3.1, Air Quality Assessment Methods, those two models were used for quantitative determination of effects, effect findings, and mitigation efficacy.

3.6.3.5 Climate Change Determination of Effects

For this analysis, an effect pertaining to air quality was analyzed based on professional practice, draft NEPA Guidance published by CEQ, and State CEQA Guidelines Appendix G (14 CCR 15000 *et seq*.). An effect was considered significant if it would:

- generate GHG emissions that may have a significant impact on the environment;
- conflict with an applicable plan adopted for the purpose of reducing GHG emissions.

3.6.3.6 Climate Change Effects and Mitigation Measures

3.6.3.6.1 No Action Alternative

To recap from Chapter 2, Alternatives, the No Action Alternative is the continuation of the existing deficiencies along the nine levee reaches and absence of levee alternatives to increase the level of protection. Current levee operations and maintenance activities would continue, but there would be no construction-related emissions from program implementation or maintenance.

Without improvements to the levee system, the risk of levee failure would remain high. Under these conditions, any of the levee deficiencies could cause portions of the levees to fail, triggering widespread flooding and extensive damage. If a catastrophic flood were to occur, emergency flood fighting and clean-up actions would require the use of a considerable amount of heavy construction equipment. Timing and duration of use would directly correlate with flood fighting needs, but it is likely that pollutants emitted would violate air quality standards for pollutants (including those for which the area is already considered non-attainment), increase GHG emissions, and expose sensitive receptors to toxic air emissions. Depending on the magnitude of the flood, flood fighting could last for weeks or even months. Furthermore, because of the unpredictable nature of an emergency response, no BMPs to manage emissions would be in place. All of these effects could be considered significant. However, the timing, duration, and magnitude of a flood event are speculative and unpredictable, and therefore a precise determination of significance is not possible.

3.6.3.6.2 Flood and Recreation Program Alternatives

Effect CC-1: Increase in Greenhouse Gas Emissions during Construction

The principal source of GHG associated with program implementation would be temporary tailpipe emissions from construction equipment and haul trucks. Because the principal source of emissions would be internal combustion, the principal GHG produced would be CO_2. No air district in California, including YSAQMD, has formally adopted a significance threshold for analyzing GHG or CO_2 emissions generated by a proposed project or a methodology for analyzing air quality effects related to global warming. However, CARB and the major air quality agencies in the state (BAAQMD, SCAQMD] and SJVAPCD) have published draft thresholds for defining the significance of GHG emissions from construction projects and operational projects. Table 3.6-6 summarizes the currently proposed thresholds as published by those air quality agencies.

Table 3.6-6. Currently Proposed GHG Significance Thresholds

	GHG Threshold for Long-Term Operational Phase (metric tons/year of CO_2-equivalnet		
Air Quality District	Industrial Projects	Commercial and Residential Projects	GHG Threshold for Temporary Construction Projects
BAAQMD 2009	10,000	1,100	Best management practices for biofuel use and waste recycling
SCAQMD 2008	10,000	3,000	30-year amortization of total construction emissions, with the amortized value compared to the appropriate Industrial or Commercial/Residential threshold.
SJVAPCD 2009	7,000	Not yet proposed	Not yet proposed
CARB 2008	7,000	Not yet proposed	Not yet proposed

It is possible that proposed projects may be subject to the future GHG regulations at the time of project-level permitting and construction.

Because GHG emitted from an individual project will persist in the atmosphere for over 100 years and contribute to long-term climate change, the assessment of GHG impacts should be evaluated based on the combined projects comprising the overall levee improvement program, rather than the individual projects. The program is designed to improve roughly 50 miles of levee, with a design life of roughly 50 years. Thus, for purposes of comparing to the GHG significance thresholds in Table 3.6-6, the combined emissions from the 50-mile program should be considered, and amortized over the 50-year design life of the project. Assuming the levee improvement program is an industrial project, the most restrictive GHG emission threshold listed in Table 3.6-6 is 7,000 metric tons per year, amortized over the 50-year design life.

To assess the significance of the forecast program-wide GHG emissions, the emission estimates for the two currently-proposed EIPs were considered, and then extrapolated to estimate the program-wide emissions. The estimated emissions are as follows:

- CHP Academy EIP. This 4,500-foot project is forecast to emit 1,290 tons (1,170 metric tons) of GHG from direct and indirect sources (see Section 4.83.2 in the Air Quality and Climate Change section).

- The Rivers EIP. This 6,500-foot project is forecast to emit 1,786 tons (1,620 metric tons) of GHG (see Section 5.83.2 in the Air Quality and Climate Change section).

Based on the average of those two individual projects, future levee improvements are expected to emit 1,340 metric tons of GHG per mile of levee improvement. By extrapolating that value over the 50-mile levee reach, the overall improvement program is expected to generate a total of 67,000 metric tons of GHG. Amortized over the 50-year design life for the levee program, the equivalent annual GHG emission rate would be 1,340 metric tons per of CO_2–equivalent.

The amortized 50-year average GHG emission rate of 1,340 metric tons per year is considerably lower than the presumptive significance threshold of 7,000 metric tons per year. Therefore, based on this preliminary emission calculation the GHG impacts caused by emissions from the overall program are considered to be less than significant. If future refined emission forecasts indicate the program-wide emissions could exceed the presumptive emission threshold, then mitigation measure AQ-MM-5 would be implemented. After implementation of the mitigation measure the effects would be less than significant.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall ▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Closure structure ▪ Interior drain ▪ Jet grouting ▪ Relief wells	▪ Seepage berm ▪ Sheet pile wall ▪ Slurry cutoff wall ▪ Slope flattening ▪ Stability berm ▪ Rock slope protection ▪ Setback levee ▪ Vegetation removal
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect would occur in all nine program reaches.

Effect CC-1 Finding	With Mitigation
Potentially significant	Less than significant

Mitigation

Mitigation Measure CC-MM-1: Implement Measures to Minimize Greenhouse Gas Emissions during Construction

The following measures could be considered to lower GHG emissions during the construction. These mitigation measures combine the most stringent aspects of the currently proposed mitigation measures published by BAAQMD (2009) and SCAQMD (2008).

- Comply with all applicable future GHG regulations at the time of project-level permitting and construction.
- Use biodiesel fuel to fuel a substantial portion of the diesel-powered equipment and vehicles (e.g., 15% of the vehicles, as proposed by the BAAQMD). However, it is important to note that according to a recent EPA report (U.S. Environmental Protection Agency 2009b), some renewable fuels (e.g., ethanol and recycled vegetable oil biodiesel) could result in less GHG emissions than petroleum fuels, while some renewable fuels (e.g., soy-based biodiesel) might increase GHG emissions. Therefore, the construction contractors should be cautious with the use of appropriate biodiesel fuels, and should avoid using soy-based biodiesel as an attempt to reduce GHG emissions.
- Encourage construction workers to carpool.
- Recycle at least 50% of construction waste and demolition debris.
- Purchase at least 10% of the building materials and imported soil from sources within 100 miles of the project site.
- Purchase GHG offset for program-wide GHG emissions (direct emissions plus indirect emissions from on-road haul trucks plus commute vehicles) exceeding future state or Federal significance thresholds applicable at the time of construction. If no GHG significance thresholds have been formally adopted at the time of permitting, then a presumptive GHG threshold of 7,000 metric tons CO_2-equivalent (amortized over the 50-year life of the levee program) should be used to define the offset requirement. The 7,000 metric ton presumptive threshold matches the lowest industrial project threshold that has been proposed by any air quality agency in California as of the date of this study (Table 3.6-6). All purchased offsets must be verifiable under protocols set by the California Climate Action Registry, the Chicago Climate Exchange, or comparable auditing programs.

Implementation of these mitigation measures would reduce the impacts to a less-than-significant level.

Effect CC-2: Conflict with an Applicable Plan, Policy or Regulation Adopted for the Purpose of Reducing the Emissions of Greenhouse Gases

The WSLIP does not pose any apparent conflict with the goals of AB 32, the key elements and GHG reduction measures in the Climate Change Scoping Plan, or any other plans for reduction or mitigation of GHGs. To date, no federal, state, or local agency with jurisdiction over the WSLIP has adopted plans or regulations that set specific goals for emission limits or emission reductions applicable to construction projects similar to the levee improvements projects that would be proposed under the WSLIP. As described in Effect AQ-6, the average forecast emissions from the implementation of the WSLIP were compared to conservatively low presumptive significance thresholds that were derived from the draft GHG guidelines published by several local air quality

agencies. The forecast emission rates are well below the presumptive significant threshold. Therefore, the overall WSLIP would not conflict with or obstruct the implementation of greenhouse gas emission reduction plans. This effect is less than significant.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall	▪ Seepage berm
	▪ Levee raise (in place)	▪ Sheet pile wall
	▪ Levee raise (adjacent)	▪ Slurry cutoff wall
	▪ Levee raise (full)	▪ Slope flattening
	▪ Closure structure	▪ Stability berm
	▪ Interior drain	▪ Rock slope protection
	▪ Jet grouting	▪ Setback levee
	▪ Relief wells	▪ Vegetation removal
Recreation	▪ Trails	▪ Developed water access
	▪ Riverside parks	▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect would occur in all nine program reaches.

Effect CC-2 Finding	With Mitigation
Less than significant	N/A

Effect CC-3: Changes in Flood Frequency and Floodwater Elevation Caused by Global Climate Change

Global climate change could affect the hydrology of the Sacramento River, including the frequency of future flood events and the intensity of future flood events. As described in Section 3.2, Flood Control and Geomorphology, Projections of Future Mean Sea Level Change (p.3.2-51), the WSLIP program area is relatively insensitive to the projected changes in sea level rise. In the program area, the Port of Sacramento and the DWSC see the largest increases resulting from sea-level rise. The DWSC is primarily backwater controlled and is hydraulically connected to the rest of the flood system fairly close to the sea (i.e., North Delta). The WSLIP design for the DWSC indicates there is adequate freeboard available to accommodate a water surface increase of the magnitudes reported herein due to sea-level rise and still maintain the minimum project design freeboard of three feet. This effect is less than significant.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall ▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Closure structure ▪ Interior drain ▪ Jet grouting ▪ Relief wells	▪ Seepage berm ▪ Sheet pile wall ▪ Slurry cutoff wall ▪ Slope flattening ▪ Stability berm ▪ Rock slope protection ▪ Setback levee ▪ Vegetation removal
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect would occur in all nine program reaches.

Effect CC-3 Finding	With Mitigation
Less than significant	N/A

Section 3.7

Noise

3.7.1 Introduction

This section describes the regulatory and environmental setting for noise, effects on noise that would result from the proposed program, and mitigation measures that would reduce these effects.

The key sources of data and information used in the preparation of this section are listed and briefly described below.

- *City of Sacramento General Plan* Noise Element (City of Sacramento 1988).
- City of Sacramento noise ordinance (City of Sacramento 1977).
- *City of West Sacramento General Plan* Noise Element (City of West Sacramento 2004).
- City of West Sacramento noise ordinance (City of West Sacramento 1994).
- *Yolo County General Plan* Noise Element (County of Yolo 1983).
- *Solano County General Plan* Noise Element (County of Solano 2008).
- Roadway Construction Noise Model User's Guide (Federal Highway Administration 2006).
- Noise control for buildings, manufacturing plants, equipment, and products (Hoover & Keith 2008).

3.7.2 Affected Environment

3.7.2.1 Fundamentals of Noise and Vibration

3.7.2.1.1 Noise

Sound is mechanical energy transmitted by pressure waves in a compressible medium such as air. Noise can be defined as unwanted sound. Sound is characterized by various parameters that include the rate of oscillation of sound waves (frequency), the speed of propagation, and the pressure level or energy content (amplitude). In particular, the sound pressure level is the most common descriptor used to characterize the loudness of an ambient sound level. The decibel (dB) scale is used to quantify sound intensity. Because sound pressure can vary enormously within the range of human hearing, the logarithmic decibel scale is used to keep sound intensity numbers at a convenient and manageable level.

The human ear is not equally sensitive to all frequencies in the entire spectrum, so noise measurements are weighted more heavily for frequencies to which humans are sensitive in a process called "A-weighting." Since humans are less sensitive to low frequency sound than to high frequency sound, A-weighted decibel (dBA) levels de-emphasize low frequency sound energy to better represent how humans hear. Table 3.7-1 summarizes typical A-weighted sound levels.

Table 3.7-1. Typical A-weighted Sound Levels

Common Outdoor Activities	Noise Level (dBA)	Common Indoor Activities
	110	Rock band
Jet flyover at 1,000 feet		
	100	
Gas lawnmower at 3 feet		
	90	
Diesel truck at 50 feet at 50 mph		Food blender at 3 feet
	80	Garbage disposal at 3 feet
Noisy urban area, daytime		
Gas lawnmower, 100 feet	70	Vacuum cleaner at 10 feet
Commercial area		Normal speech at 3 feet
Heavy traffic at 300 feet	60	
		Large business office
Quiet urban daytime	50	Dishwasher in next room
Quiet urban nighttime	40	Theater, large conference room (background)
Quiet suburban nighttime		
	30	Library
Quiet rural nighttime		Bedroom at night, concert hall (background)
	20	
		Broadcast/recording studio

Different types of measurements are used to characterize the time-varying nature of sound. These measurements include the equivalent sound level (L_{eq}), the minimum and maximum sound levels (L_{min} and L_{max}), percentile-exceeded sound levels (L_{xx}), the day-night sound level (L_{dn}), and the community noise equivalent level (CNEL). Below are brief definitions of these measurements and other terminology used in this section:

- **Sound.** A vibratory disturbance created by a vibrating object, which, when transmitted by pressure waves through a medium such as air, is capable of being detected by a receiving mechanism, such as the human ear or a microphone.
- **Noise.** Sound that is loud, unpleasant, unexpected, or otherwise undesirable.
- **Ambient noise.** The composite of noise from all sources near and far in a given environment exclusive of particular noise sources to be measured.
- **Decibel (dB).** A unitless measure of sound on a logarithmic scale, which indicates the squared ratio of sound pressure amplitude to a reference sound pressure amplitude. The reference pressure is 20 micro-pascals.

- **A-weighted decibel (dBA).** An overall frequency-weighted sound level in decibels that approximates the frequency response of the human ear.
- **Equivalent sound level (L_{eq}).** The average of sound energy occurring over a specified period. In effect, L_{eq} is the steady-state sound level that in a stated period would contain the same acoustical energy as the time-varying sound that actually occurs during the same period.
- **Exceedance sound level (L_{xx}).** The sound level exceeded XX percent of the time during a sound level measurement period. For example, L_{90} is the sound level exceeded 90 percent of the time, and L_{10} is the sound level exceeded 10 percent of the time. L_{90} is typically considered to represent the ambient noise level.
- **Maximum and minimum sound levels (L_{max} and L_{min}).** The maximum or minimum sound level measured during a measurement period.
- **Day-night level (L_{dn}).** The energy average of the A-weighted sound levels occurring during a 24-hour period, with 10 dB added to the A-weighted sound levels occurring during the period from 10:00 p.m. to 7:00 a.m.
- **Community noise equivalent level (CNEL).** The energy average of the A-weighted sound levels occurring during a 24-hour period with 5 dB added to the A-weighted sound levels occurring during the period from 7:00 p.m. to 10:00 p.m. and 10 dB added to the A-weighted sound levels occurring during the period from 10:00 p.m. to 7:00 a.m.

L_{dn} and CNEL values rarely differ by more than 1 dB. As a matter of practice, L_{dn} and CNEL values are considered to be equivalent and are treated as such in this assessment. In general, human sound perception is such that a change in sound level of 3 dB is just noticeable, a change of 5 dB is clearly noticeable, and a change of 10 dB is perceived as doubling or halving sound level.

For a point source such as a stationary compressor, sound attenuates based on geometry at rate of 6 dB per doubling of distance. For a line source such as free- flowing traffic on a freeway, sound attenuates at a rate of 3 dB per doubling of distance. Atmospheric conditions including wind, temperature gradients, and humidity can change how sound propagates over distance and can affect the level of sound received at a given location. The degree to which the ground surface absorbs acoustical energy also affects sound propagation. Sound that travels over an acoustically absorptive surface such as grass attenuates at a greater rate than sound that travel over a hard surface such as pavement. The increased attenuation is typically in the range of 1 to 2 dB per doubling of distance. Barriers such as buildings and topography that block the line of site between a source and receiver also increase the attenuation of sound over distance.

Auditory and non-auditory effects can result from excessive or chronic exposure to elevated noise levels. Auditory effects of noise on people can include temporary or permanent hearing loss. Non-auditory effects of exposure to elevated noise levels include sleep disturbance, speech interference, and psychological effects, such as annoyance. Land use compatibility standards for noise are typically based on research related to these non-auditory effects.

3.7.2.1.2 Vibration

Operation of heavy construction equipment, particularly pile driving and other impulsive devices such as pavement breakers, create seismic waves that radiate along the surface of the earth and downward into the earth. These surface waves can be felt as ground vibration. Vibration from operation of this equipment can result in effects ranging from annoyance of people to damage of

structures. Varying geology and distance will result in different vibration levels containing different frequencies and displacements. In all cases, vibration amplitudes will decrease with increasing distance.

As seismic waves travel outward from a vibration source, they excite the particles of rock and soil through which they pass and cause them to oscillate. The actual distance that these particles move is usually only a few ten-thousandths to a few thousandths of an inch. The rate or velocity (in inches per second [in/sec]) at which these particles move is the commonly accepted descriptor of the vibration amplitude, referred to as the peak particle velocity (ppv). Table 3.7-2 summarizes typical vibration levels generated by construction equipment (Federal Transit Administration 2006).

Table 3.7-2. Vibration Source Levels for Construction Equipment

Equipment	PPV at 25 feet
Pile driver (impact)	0.644 to 1.518
Pile drive (sonic)	0.170 to 0.734
Vibratory roller	0.210
Hoe ram	0.089
Large bulldozer	0.089
Caisson drilling	0.089
Loaded trucks	0.076
Jackhammer	0.035
Small bulldozer	0.003

Source: Federal Transit Administration 2006.

Vibration amplitude attenuates over distance and is a complex function of how energy is imparted into the ground and the soil conditions through which the vibration is traveling. The following equation can be used to estimate the vibration level at a given distance for typical soil conditions. PPV_{ref} is the reference ppv at 25 feet from Table 3.7-2:

$$PPV = PPV_{ref}\left(\frac{25}{distance}\right)^{1.5}$$

Table 3.7-3 summarizes typical human response to steady state vibration such as that produced by typical non-impact construction activity.

Table 3.7-3. Human Response to Steady State Vibration

PPV	Human Response
3.6 (at 2 Hz) – 0.4 (at 20 Hz)	Very disturbing
0.7 (at 2 Hz) – 0.17 (at 20 Hz)	Disturbing
0.10	Strongly perceptible
0.035	Distinctly perceptible
0.012	Slightly perceptible

Source: California Department of Transportation 2004.

Table 3.7-4 summarizes typical human response to transient vibration that is usually associated with transitory impact construction sources such as pile driving activity.

Table 3.7-4. Human Response to Transient Vibration

PPV	Human Response
2.0	Severe
0.9	Strongly perceptible
0.24	Distinctly perceptible
0.035	Barely perceptible

Source: California Department of Transportation 2004.

3.7.2.2 Regulatory Setting

3.7.2.2.1 Federal

There are no Federal noise regulations applicable to the proposed program.

3.7.2.2.2 State

There are no state noise standards that would apply directly to the program. The *General Plan Guidelines* published by the Governor's Office of Planning and Research (2003) include recommendations for maximum noise exposure based on type of land use. These recommendations are available for counties and cities to adopt as part of their state-mandated requirement in establishing policies and standards in their general plans regarding incompatibility issues between land uses as it relates to noise exposure.

There are no applicable Federal, state, or local quantitatively-defined regulations relating to vibration resulting from construction activities. Thresholds for annoyance and structural damage reported by Caltrans (2004) are used in this analysis. Tables 3.7-3 and 3.7-4 summarize human response/annoyance thresholds. Table 3.7-5 summarizes vibration damage thresholds.

Table 3.7-5. Maximum Vibration Levels for Preventing Damage to Structures

Type of Situation	Limiting Velocity (in/sec)
Historic sites or other critical locations	0.1
Residential buildings, plastered walls	0.2 to 0.3
Residential buildings in good repair with gypsum board walls	0.4 to 0.5
Engineered structures, without plaster	1.0 to 1.5

Source: California Department of Transportation 2004.

3.7.2.2.3 Local

The program area spans several local municipalities including the City of West Sacramento, as well as Yolo and Solano counties. Program noise also has the potential to affect land uses and noise-

sensitive receptors in the City of Sacramento. Each of these local governments has established goals and policies relating to community noise exposure. They are summarized below.

City of West Sacramento Noise Ordinance

Most of the levee alternatives for the proposed program would be done within the City of West Sacramento. The City noise ordinance is the primary enforcement tool for the operation of locally regulated noise sources, such as construction activity or outdoor recreation facilities, and is set forth in Chapter 17.32 of the City Code. The City noise ordinance sets noise level performance standards for non-transportation noise sources, which are summarized in Table 3.7-6. Examples of non-transportation noise sources include construction equipment, industrial operations, outdoor recreation facilities, HVAC units, and loading docks. The City of West Sacramento's noise ordinance does not specify an exemption for temporary daytime construction activity, so all construction associated with the proposed program must comply with the daytime and nighttime noise limits listed in Table 3.7-6.

Table 3.7-6. City of West Sacramento Non-Transportation Noise Level Standards

		Exterior Noise Levels		Interior Noise Levels	
Land Use	Noise Level Descriptor	Daytime (7:00 a.m. to 10:00 p.m.)	Nighttime (10:00 p.m. to 7:00 a.m.)	Daytime (7:00 a.m. to 10:00 p.m.)	Nighttime (10:00 p.m. to 7:00 a.m.)
Residential	Hourly L_{eq}, dBA	50	45	45	35
	Max. Level, dBA	70	65	–	–
Transient Lodging	Hourly L_{eq}, dBA	–	–	45	35
Hospital, nursing homes	Hourly L_{eq}, dBA	–	–	45	35
Theatres, auditoriums, music halls	Hourly L_{eq}, dBA	–	–	35	35
Churches, meeting halls	Hourly L_{eq}, dBA	–	–	40	40
Office buildings	Hourly L_{eq}, dBA	–	–	45	45
Schools, libraries, museum	Hourly L_{eq}, dBA	–	–	45	45

Source: City of West Sacramento 1994.

Note: Each of the noise levels specified above will be lowered by five dB for simple tone noises, noises consisting primarily of speech or music, or for recurring impulsive noises. These noise level standards do not apply to residential units established in conjunction with industrial or commercials uses (e.g., caretaker dwellings)

In addition, the City Code stipulates that no operation shall be installed which by its construction or nature habitually or consistently produces noticeable vibration beyond the property line. As is discussed above, vibration from non-impact construction equipment (which typically produces steady state vibration) is not anticipated to result in a significant effect. As indicated in Table 3.7-4, human response to transient vibration sources (such as impact pile driving) typically becomes "distinctly perceptible" at or above 0.24 in/sec ppv (California Department of Transportation 2004).

West Sacramento General Plan

The primary purpose of the Noise Element of the *West Sacramento General Plan* is to protect city residents from the harmful effects of excessive noise (City of West Sacramento 1990). To this end,

the Noise Element serves to set acceptable limits for the land use compatibility of new developments or land uses as it relates to noise exposure. The Noise Element sets the following policies for new development and planning purposes that may relate to the proposed program.

Policies

Policy 2: Where proposed non-residential land uses are likely to produce noise levels exceeding the performance standards if Table II-4 [Table 3.7-7] at existing or planned uses shown in Table II-4 [Table 3.7-7], an acoustical analysis shall be required as part of the environmental review process so that noise mitigation may be included in the project design. Noise created by new proposed non-transportation noise sources shall be mitigated so as not to exceed the noise level standards of Table II-4 [Table 3.7-7] as measured immediately within the property line of land uses designated in Table II-4 [Table 3.7-6].

Policy 4: New development of land uses contained in Table II-6 [Table 3.7-7] will not be permitted in areas exposes to existing or projected levels of noise from transportation noise sources which exceed the levels specified in Table II-6 [Table 3.7-8]. Where the land uses contained in Table II-6 [Table 3.7-8] are proposed in areas exposed to existing or projected exterior noise levels exceeding the levels specified in Table II-6 [Table 3.7-8], an acoustical analysis shall be required and appropriate mitigation shall be included in the project design.

Policy 7: Where noise mitigation measures are required to achieve the standards of Tables II-4 [Table 3.7-6] and II-6 [Table 3.7-7], the emphasis of such measures shall be placed upon site planning and project design. The use of noise barriers shall be considered a means of achieving the noise standards only after all other practical design-related noise mitigation measures have been integrated into the project.

In addition to the policies set forth in the *West Sacramento General Plan*, the *City of West Sacramento General Plan Background Document* states that "Sporting events such as softball games are conducted at city parks, with some games played at night. Public reaction to the noise produced by such activities may range from supportive to antagonistic, depending upon individual perceptions. In any case, late-night games with their attendant crowd noise and traffic can be annoying to nearby residents. To guard against adverse public reaction to nighttime sporting events at city parks, activities and use of public address systems should be limited to 10:00 p.m. or 11:00 p.m., depending upon neighborhood reactions. New facilities for sporting events should be designed to control crowd and public address system impacts."

Table 3.7-7. City of West Sacramento Maximum Allowable Noise Exposure—Transportation Noise Sources

Land Use	Outdoor Activity Areas[1] L_{dn}/CNEL, dB	Interior Spaces	
		L_{dn}/CNEL, dB	L_{eq}, dB[2]
Residential	60[3]	45	–
Transient Lodging	60[3]	45	–
Hospitals, nursing homes	60[3]	45	–
Theatres, auditoriums, music halls	–	–	35
Churches, meeting halls	60[3]	–	40
Office buildings	–	–	45
Schools, libraries, museum	–	–	45
Playgrounds, neighborhood parks	70	–	–

Note:
[1] Where the location of outdoor activity is unknown, the exterior noise level standard shall be applied to the property line of the receiving land use.
[2] As determined for a typical worst-case hour during period of use.
[3] Where it is not possible to reduce noise in outdoor activity areas to 60 dB Ldn/CNEL or less using a practical application of the best-available noise reduction measures, an exterior noise level of up to 65 dB Ldn/CNEL may be allowed, provided that practical exterior noise level reduction measures have been implemented and that interior noise levels are in compliance with this table. An exterior noise level of 70 dB Ldn/CNEL shall be allowed in the triangle specific plan area and the Washington specific plan area.

Solano County

Minor amounts of levee improvement would be done in unincorporated Solano County under the proposed program. Solano County has not established a noise ordinance that sets numerical or qualitative limits on the construction noise that would be generated by the proposed program. The primary purpose of the noise section of the Public Health and Safety Chapter of the *Solano County General Plan* is to develop strategies for reducing excessive noise exposure through cost-effective measures and appropriate zoning that avoids placing incompatible land uses in proximity of each other. The General Plan has established interior and exterior noise level standards for new land use and development proposals in terms of acceptable noise exposure. These standards would not apply directly to the program.

Yolo County

Minor amounts of levee improvement would be done in unincorporated Yolo County under the proposed program. To date, Yolo County has not adopted a noise ordinance that sets numerical or qualitative limits on the construction noise that would be generated by the proposed program. The *Yolo County General Plan* sets forth policies relating to noise, including a policy that Yolo County will adopt a comprehensive noise ordinance. Yolo County is currently in the process of a general plan update.

City of Sacramento Noise Ordinance

The proposed program does not include any levee alternatives within the City of Sacramento, but some construction would be done directly across the river from homes in Sacramento. The City of Sacramento's noise ordinance limits described below have been used in this EIR as a noise impact criterion for homes inside the city.

The City of Sacramento noise ordinance is the primary enforcement tool for the operation of locally regulated noise sources, such as construction activity, and is set forth in Chapter 8.68 of the City Code. The noise ordinance sets exterior noise level standards for noise sources that affect residential or agricultural property. These exterior noise level performance standards are summarized in Table 3.7-8. Noise associated with the erection (including excavation), demolition, alteration, or repair of any structure occurring between 7:00 a.m. and 6:00 p.m., Monday through Saturday, and between 9:00 a.m. and 6:00 p.m. on Sunday is exempted from the provisions of the City noise ordinance.

Table 3.7-8. City of Sacramento Exterior Noise Level Standards

Cumulative Duration of the Intrusive Sound in Any One Hour	Daytime[1] (7:00 a.m. to 10:00 p.m.)	Nighttime[1] (10:00 p.m. to 7:00 a.m.)
30 Minutes	55	50
15 Minutes	60	55
5 Minutes	65	60
1 Minute	70	65
Level not to be exceeded	75	70
Resultant 1-hour L_{eq}	59	54

Source: City of Sacramento 1977.

Notes:

Each of the noise limits specified shall be reduced by five dBA for impulsive or simple tone noise, or for noises consisting of speech or music;

If the ambient noise level exceeds that permitted by any of the first four noise level categories, the allowable noise limit shall be increased in five dB increments in each category to encompass the ambient noise level. If the ambient noise level exceeds the fifth noise level category, the maximum ambient noise level shall be the noise limit for that category.

City of Sacramento General Plan

The Noise Element of the *City of Sacramento General Plan* establishes interior and exterior noise level standards for planning purposes to ensure land use compatibility for new zoned developments as it relates to noise exposure. The City of Sacramento is currently in the process of a general plan update. The Noise Element sets noise level standards for new development and planning purposes, which do not pertain directly to the proposed program.

3.7.2.3 Environmental Setting

Noise-sensitive land uses are those locations where noise can interfere with primary activities. These used include places where people sleep, such as residences and hospitals. Other noise-sensitive uses include schools, libraries, places of worship, and areas of recreation during hours of

normal human use. Vibration-sensitive uses are similar to noise-sensitive uses, but are in large part limited to residential, historical structures, and vibration-sensitive technical facilities (i.e., biomedical research).

Noise-sensitive land uses within the program vicinity are primarily residential. Other noise-sensitive land uses include schools (i.e., Riverbank Elementary), hospitals (i.e., Sutter Health), hotels and motels (i.e., Embassy Suites Riverfront Promenade), and areas of recreation (i.e., Bryte Park and the Jedediah Smith Recreational Trail).

Primary noise sources in the program vicinity include vehicular traffic on highways (i.e., I-80, I-5, SR 84, SR 275—Tower Bridge Gateway, and US 50) and local roadways, and industrial and agricultural operations. Secondary noise sources include airplane flyovers (i.e., to and from the CHP Academy and Sacramento Executive), boating traffic on the Sacramento River, Raley Field, and miscellaneous community noise sources such as dogs or property maintenance.

Population density and ambient noise levels tend to be closely correlated. Areas that are not urbanized are relatively quiet, while areas that are more urbanized are subjected to higher noise levels due to roadway traffic, industrial activities, and other human activities. Table 3.7-9 summarizes typical ambient noise levels based on population density.

Table 3.7-9. Population Density and Associated Ambient Noise Levels

	dBA, L_{dn}
Rural	40–50
Small town or quiet suburban residential	50
Normal suburban residential	55
Urban residential	60
Noisy urban residential	65
Very noise urban residential	70
Downtown, major metropolis	75–80
Adjoining freeway or near a major airport	80–90

Sources: Hoover and Keith 2008.

As land use classifications and densities vary widely throughout the program area, so does the existing noise environment. Existing noise levels are relatively low in rural areas (40 to 50 L_{dn}) and can be in the range 80 to 90 L_{dn} in locations nearest major highways with larger traffic volumes, such as I-80.

3.7.3 Environmental Consequences

This section describes the potential effects on noise from implementation of the proposed program. It describes the methods used to determine the effects of the program and lists the thresholds used to conclude whether an effect would be significant. Measures to mitigate (i.e., avoid, minimize, rectify, reduce, eliminate, or compensate for) significant effects accompany each effect discussion.

3.7.3.1 Assessment Methods

This analysis focuses on the potential construction-related and operational noise effects associated with the program and its alternatives. Methods recommended by the Federal Transit Administration have been used to assess construction noise. Potential noise effects associated with construction activities have been evaluated by assuming the simultaneous operation of multiple pieces of heavy equipment as a reasonable upper bound for noise effects. For the program level environmental consequences, specific site plan drawings and project-level information are not yet available. Therefore, it is assumed that construction activities may occur at any point along a given levee reach.

Temporary groundborne vibration from construction activity has also been assessed using methods *recommended by the Federal Transit Administration (2006).

3.7.3.2 Determination of Effects

The environmental checklist in the State CEQA Guidelines Appendix G (14 CCR 15000 et seq.) provides guidance to be used in determining the significance of noise effects. A noise effect is normally considered significant if it would:

- expose persons to or generate noise levels in excess of applicable standards;
- result in a substantial permanent increase in ambient noise levels in the project vicinity above levels existing without the project;
- result in a substantial temporary or periodic increase in ambient noise levels in the project vicinity above levels existing without the project;
- expose persons to vibration or generation of excessive groundborne noise levels;
- expose people residing or working in the area to excessive noise levels, for a project located within an airport land use plan or, where such a plan has not been adopted, within 2 miles of a public airport or public use airport; or
- expose people residing or working in the project area to excessive noise levels, for a project within the vicinity of a private airstrip.

For the purposes of this analysis, a noise or vibration effect is considered to be significant if:

- construction noise levels exceed allowable numerical limits specified by the City of West Sacramento or the City of Sacramento, for receivers in those jurisdictions.
- construction noise levels at receivers located where there are no numerical noise limits (i.e., other than the cities of West Sacramento or Sacramento) exceed 70 dBA L_{eq} during the day, or 60 dBA L_{eq} at night. Those noise criteria were established for this analysis based on recommended values by the Federal Transit Administration 2006, adjusted downward by 10 dBA to account for the relatively quiet baseline conditions throughout the study area.
- construction vibration ppv would exceed 0.2 in/sec (potential damage at plaster-walled structures) or 0.24 in/sec (human response threshold for “distinctly perceptible” due to transient vibration sources) at any structure or occupied building. 0.2 in/sec will be the governing threshold for assessing the significance of vibration.

3.7.3.2.1 Effect Assumptions

The following assumptions regarding program effects on noise in the study area have been made for this analysis:

- The program does not propose to introduce any new noise-sensitive uses where people would live or work into the program area. There are no significant sources of groundborne vibration associated with operation of the program. Therefore, operation of the program would have no effect related to the exposure of persons to, or generation of excessive groundborne vibration or groundborne noise levels.
- Groundborne noise occurs when groundborne vibration causes the ground surface and structures to radiate audible acoustical energy. It is primarily an issue for underground rail systems and is not a concern for groundborne noise generated by construction or maintenance equipment because airborne noise from construction and maintenance equipment typically overshadows the groundborne noise generated by the equipment. Accordingly, groundborne noise is not considered further in this analysis.
- The maintenance of certain levee alternatives would involve intermittent vehicular trips to inspect the proper functioning of the alternative and/or light mechanical equipment operation to conduct vegetative weeding, irrigation, repair or cleaning activities as needed. These intermittent vehicular trips and light maintenance activities, by their very nature and frequency, are considered less than significant.
- There are no significant sources of groundborne vibration associated with operation of the proposed project. Therefore, operation of the proposed project would have no effect related to the exposure of persons to, or generation of excessive groundborne vibration or groundborne noise levels and evaluation of this effect is not applicable, and is not discussed further.

3.7.3.3 Effects and Mitigation Measures

3.7.3.3.1 No Action Alternative

To recap from Chapter 2, Alternatives, the No Action Alternative is the continuation of the existing deficiencies along the nine levee reaches and absence of flood program alternatives to increase the level of protection. Current levee operations and maintenance activities would continue, but there would be no noise or vibration associated with new construction or operational activities.

Without improvements to the levee system, the risk of levee failure would remain high. Under these conditions, any of the levee deficiencies could cause portions of the levees to fail, triggering widespread flooding and extensive damage. If a catastrophic flood were to occur, emergency flood fighting and clean-up actions would require the use of a considerable amount of heavy construction equipment. Timing and duration of use would directly correlate with flood fighting needs, but could last for days, weeks, even months. Depending on the magnitude of the flood, people may or may not be present during flood fighting activities. If flooding occurred only in West Sacramento, nearby Sacramento residents could still be residing and working near a clean-up area, exposing them to excessive noise and vibration levels for extended periods of time. Furthermore, because of the unpredictable nature of an emergency response, compliance with local noise ordinances and implementation of BMPs to manage noise levels would not be possible. All of these effects could be

considered significant. However, the timing, duration and magnitude of a flood event are speculative and unpredictable, and therefore a precise determination of significance is not possible.

3.7.3.3.2 Proposed Construction Activities

All flood program alternatives (as well as the construction of certain recreation program elements such as trails, parks, kiosks, amphitheaters, boat launches, docks and piers) would require the use of heavy construction equipment. Additionally, the operation of heavy equipment may generate groundborne vibration that could be perceptible at residences or other sensitive land uses close to construction activity. Vibration levels due to standard construction activity, aside from pile driving, are generally in the range of 0.035 to 0.21 in/sec ppv at a distance of 25 feet (Federal Transit Administration 2006). Vibration levels caused by pile driving are typically higher and will depend on many factors, including the type of pile driving method (impact, vibratory, or sonic), the type and length of piles, the distance to the nearest sensitive receptor, and the soil strata conditions. In general, vibration levels due to pile driving are approximately 0.644 to 1.518 inches per second ppv for impact pile driving and 0.170 to 0.734 in/sec ppv for sonic (vibratory) pile driving (Federal Transit Administration 2006).

Table 3.7-10 summarizes typical construction noise emission levels for various types of equipment likely to be used throughout the course of the program.

Table 3.7-10. Typical Construction Equipment Noise Emission Levels

Equipment	Typical Noise Level (L_{max})[1]	Equipment	Typical Noise Level (L_{max})[1]
Air compressor	78	Grader	85
Auger drill rig	84	Haul truck[2]	76

The following discussion provides a brief description of the various treatments proposed and the corresponding noise level projections based on a construction site situation assuming the simultaneous operation in one location of the three loudest pieces of construction equipment.

Adjacent, Full and In Place Levee Raises, Setback Levee, Flood Wall, Seepage Berm, Interior Drain, Stability Berm Treatments

Construction of the three levee raise options (full, adjacent, and in place), the setback levee, the flood wall, the seepage berm, the interior drain, and the stability berm treatment options would all require the use of bulldozers, motor graders, sheepsfoot compactors, and haul trucks. Certain treatment options listed above may also involve the use of water trucks. The flood wall treatment option would require the use of a crane. The three loudest pieces for all of the above-mentioned treatment options would likely be the grader, compactor, and dozer. Table 3.7-11 summarizes projected noise levels for these pieces of equipment at various distances. These noise levels are also generally representative of noise levels that could occur at staging areas.

Slope Flattening

Construction equipment proposed for use under the slope flattening treatment option includes motor graders, sheepsfoot rollers, haul trucks, and water trucks. Table 3.7-12 summarizes noise levels projected from the simultaneous use of a grader, roller, and large truck (haul or water truck).

Table 3.7-12. Slope Flattening: Projected Construction Noise Levels due to a Grader, Roller, and Large Truck in the Program Vicinity

Rock Slope Protection

This treatment option would involve protection of portions of a given levee through the method of stone placement. Construction equipment proposed for use under the rock slope protection treatment includes one excavator and one loader. Table 3.7-13 summarizes noise levels projected from these pieces of equipment at various distances.

Table 3.7-13. Rock Slope Protection: Projected Construction Noise Levels due to an Excavator and a Loader

Note: This calculation does not include the effects, if any, of local shielding from walls, topography or other barriers which may reduce sound levels further.

Sheet Pile Wall

Under this treatment option, sheet piles would be driven into the levee crown by a hydraulic or pneumatically-operated pile driving head attached to a crane. If the levee material is particularly solid, pre-drilling may be necessary. The pre-drilling of pile holes would reduce the number of impacts needed during pile driving activities and would reduce the overall duration of noise and vibration exposure to surrounding sensitive receptors, thus lessening the overall program effect. Additionally, a haul truck would be required to deliver materials. Table 3.7-14 summarizes noise levels projected from the simultaneous use of a crane, haul truck, and impact pile driver at various distances.

Slurry Cutoff Wall

There are two methods for constructing a slurry cutoff wall: 1) conventional slot trench and 2) deep soil mixing. Either of these methods could be utilized to construct slurry cutoff walls in the program area.

Conventional Slot Trench

Construction equipment proposed for use under the slurry cutoff wall—conventional slot trench method include a long-reach trackhoe, three to four dump trucks, loaders, a rough terrain forklift, compactors, maintainers, a water truck, and two additional loaders at a to-be-determined staging/mixing area located adjacent to the landside of the levee. Dump trucks would haul material between the mixing area and the trench site. The three loudest pieces of equipment under this treatment option would be the compactor, dozer, and excavator. Table 3.7-15 summarizes noise levels projected from the simultaneous use of these pieces of equipment at various distances.

Table 3.7-15. Slurry Trench: Projected Construction Noise Levels due to a Compactor, Dozer, and Excavator in the Program Vicinity

Calculations based on Federal Transit Administration 2006.

Note: This calculation does not include the effects, if any, of local shielding from walls, topography or other barriers which may reduce sound levels further.

Deep Soil Mixing

Construction equipment proposed for use under the slurry cutoff wall—deep soil mixing method would include two to four mixing augers supported by a crane, a batch plant, a scraper, and an excavator. A scraper and loader would also be used at a to-be-determined stockpile/staging area. Additionally, a haul truck would be required to haul spoils off site. The three loudest pieces of equipment under this treatment option would be the auger, scraper, and batch plant. Table 3.7-16 summarizes noise levels projected from the simultaneous use of four augers, a scraper, and an excavator at various distances.

Note: This calculation does not include the effects, if any, of local shielding from walls, topography or other barriers which may reduce sound levels further.

Relief Wells

Construction equipment proposed for use under the relief walls treatment option would include a drill rig, an equipment support vehicle, an excavator or a backhoe, and a water supply truck. The three loudest pieces of equipment under this treatment option would be the excavator, drill rig, and water supply truck. Table 3.7-17 summarizes noise levels projected from the simultaneous use of these pieces of equipment at various distances.

In addition, the relief wells treatment option would involve the installation of a pump station. Inspection of the relief wells would be required at least on an annual basis, and observation of flow from the wells would be required during high river stages. The wells would be test-pumped every 2 years, and the discharge water from those tests would be trucked off site. Vehicular noise generated by the intermittent inspection and/or observation of the wells would be on a relatively limited basis.

Noise due to a pump station depends on several factors, including the number and type of pumps, the depth of the pumps, and the distance to the nearest noise-sensitive receptor. Pumps typically generate noise levels in the range of 68–80 dBA at a distance of 50 feet (Hoover & Keith 2008).

Closure Structure

Construction equipment proposed for use under the closure structure options includes scrapers, trench excavators, track hoes, cranes, sheepsfoot rollers, water trucks and small compactors. The three loudest pieces of equipment under this treatment option would likely be a scraper, excavator and compactor. Table 3.7-18 summarizes projected noise levels from these pieces of equipment at various distances.

Note: This calculation does not include the effects, if any, of local shielding from walls, topography or other barriers which may reduce sound levels further.

Jet Grouting

At the time of preparation of this document, an anticipated construction equipment list for jet grouting was not available. A reasonable assumption is that the noise levels from jet grouting would be comparable to the noise produced by the simultaneous operation of an air compressor and sand blasting equipment. Table 3.7-19 summarizes projected noise levels from these pieces of equipment at various distances.

Table 3.7-19. Jet Grouting: Projected Construction Noise Levels due to Jet Grouting in the Program Vicinity

3000	-36	-11	50	43

Calculations based on Federal Transit Administration 2006.

Note: This calculation does not include the effects, if any, of local shielding from walls, topography or other barriers which may reduce sound levels further.

Vegetation Removal

As is mentioned in Chapter 2, Alternatives, the vegetation removal alternative may involve hand-clearing activities using chainsaws (or trimmers) or mass clearing by bulldozers. Reference noise levels provided in Hoover & Keith (2008) indicate that a sound level of 66 dBA at 50 feet is a reasonable estimate for gasoline powered chainsaws. Table 3.7-10 indicates that bulldozers typically produce a noise level of 82 dBA at a distance of 50 feet. Where bulldozers and chainsaws are operated in the same vicinity, noise from the bulldozers would likely govern. Table 3.7-13 sound levels at various distances for a source level of 83 dBA at 50 feet. This is reasonably representative of noise from vegetation removal operations.

3.7.3.3.3 Flood and Recreation Program Alternatives

Effect NZ-1: Exposure of Sensitive Receptors to Temporary Construction-Related Noise

As is mentioned above, all flood program alternatives and certain recreation program elements (such as trails, parks, kiosks, amphitheaters, boat launches, docks and piers construction) would require the use of heavy noise-generating construction equipment.

An analysis based on the noise levels summarized in Tables 3.7-11 to 3.7-19 of all reaches by potential flood program alternatives and recreation program elements indicates that temporary periods of construction activity along all nine of the proposed levee reaches have (under some limited circumstances) the potential to result in an excess of the established determinations of effects. In general, the construction activity would be far enough from sensitive receivers so the noise levels would not exceed significance thresholds.

However, in some cases the uncontrolled noise sources have the potential to exceed the West Sacramento daytime and nighttime noise ordinance limits, which are binding regulatory requirements. In those cases WSAFCA or its contractor will develop a noise control plan as outlined in the environmental commitment to employ noise-reducing construction practices to comply with applicable noise ordinances, as described in Section 2.9, Chapter 2, Alternatives. This environmental commitment may in some cases reduce this effect to less than significant but may not always reduce effect to this level. Therefore, this effect would be less than significant to potentially significant and unavoidable. The noise control plan will identify feasible measures that will be employed to reduce construction noise where necessary, and to temporarily re-locate residents if necessary. These measures may include but are not limited to those listed below:

- scheduling the loudest and most intrusive construction activities (such as impact pile driving) during daytime hours (7:00 a.m. to 7:00 p.m.) where feasible;
- requiring that construction equipment be equipped with factory-installed muffling devices or better, and that all equipment be operated and maintained in good working order to minimize noise generation;
- locating stationary noise-generating equipment as far as practical from noise-sensitive uses;
- limiting unnecessary engine idling (i.e., more than 5 minutes);
- employing equipment that is specifically designed for low noise emission levels;
- employing equipment that is powered by electric or natural gas engines as opposed to those powered by gasoline fuel or diesel;
- placing temporary barriers between noise sources and noise-sensitive receptors or taking advantage of existing barrier features (terrain, structures, edge of trench) to block noise transmission;
- prohibiting use of backup alarms and providing an alternate warning system, such as a flagman or radar-based alarm, that is compliant with state regulations;
- displaying signs with contractor contact telephone number in a conspicuous manner such as on construction site fences;
- locating construction staging areas as far as practical from noise-sensitive receptors; and

- designing truck haul routes along roads with as few noise-sensitive receptors as possible and along roads furthest from noise-sensitive receptors.
- If noise reduction measures adequate to achieve the numerical noise ordinance limits applicable at any given location are not feasible, then WSAFCA will obtain a temporary construction noise variance from the affected jurisdiction. WSAFCA will comply with all conditions (including public notification, supplemental noise control, compensation for temporary re-location of affected residents, and other specified measures) imposed by the variance process.

The proposed improvements also have the potential to cause noise impacts at homes adjacent to the haul routes used by heavy trucks to haul fill to the levee sites. It might be necessary to do construction activity at night, which would require haul trucks to travel for 24 hours per day. If nighttime hauling is required, then noise generated by the haul trucks might be significant and unavoidable at the nearest homes.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall ▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Closure structure ▪ Interior drain ▪ Jet grouting ▪ Relief wells	▪ Seepage berm ▪ Sheet pile wall ▪ Slurry cutoff wall ▪ Slope flattening ▪ Stability berm ▪ Rock slope protection ▪ Setback levee ▪ Vegetation removal
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect would occur in all nine program reaches.

Effect NZ-1 Finding	With Mitigation
Less than significant –Significant and unavoidable	N/A

Effect NZ-2: Exposure of Sensitive Receptors to Temporary Vibration Caused by Pile Driving

The sheet pile alternative option is being considered for the Sacramento River North Levee, DWSC West Levee, DWSC East Levee and Yolo Bypass Levee reaches. Calculations based on guidance in Federal Transit Administration 2006 indicate pile driving could result in ppv vibration that exceeds 0.2 in/sec within about 100 feet of pile driving. Because of the potential for structures to be located within this distance for both the Sacramento River North Levee and DWSC East Levee reaches, this

effect is considered significant. Implementation of Mitigation Measure NZ-MM-1 would reduce this effect to less than significant.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative
Flood	▪ Sheet pile wall

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect would occur in the Sacramento River North Levee, DWSC West Levee, DWSC East Levee, and Yolo Bypass Levee reaches.

Effect NZ-2 Finding	With Mitigation
Significant	Less than significant

Mitigation

Mitigation Measure NZ-MM-1: Limit Pile-Driving Vibration and Implement a Pile-Driving Vibration Control Plan

WSAFCA will employ vibration-reducing construction practices such that pile driving vibration does not exceed 0.2 inch per second at any adjacent structure. The program applicant will prepare a vibration control plan that will identify feasible measures that will be employed to reduce construction vibration where necessary. These measures may include but are not limited to:

- maximizing the distance between pile driving and structures;
- employing resilient pile caps to reduce vibration amplitude; and
- employing alternative driving methods such as vibratory driving to reduce vibration.
- If the above reduction measures are not feasible at any given location, then WSAFCA will inspect the structure before pile driving begins, conduct vibration monitoring during pile driving, and inspect the structure again after completion of pile driving. WSAFCA will promptly take corrective measures to repair identified damages caused by the pile driving.

Effect NZ-3: Exposure of Sensitive Receptors to Intermittent Noise as a Result of Ongoing Maintenance Activities and Permanent Facility Operations

As is mentioned above, intermittent vehicular trips and light maintenance activities (such as under the flood wall, interior drain, sheet pile wall, slurry cutoff wall, and rock slope alternatives) by their very nature and frequency, are considered less than significant.

Intermittent maintenance activities under the stop log alternative would involve the use of a crane to install closures when necessary (such as a high-water event), as well as infrequent vehicular trips for inspection. Infrequent vehicular trips, due to their very nature, are not considered significant.

Based on the reference noise level for a typical crane of L_{max} 81 dBA at a distance of 50 feet, as given in Table 3.7-10, it is calculated that the 50 dBA significance threshold could be exceeded within 600 feet, and the 45 dBA threshold could be exceeded within 900 feet. Because residences are potentially located within this distance, this effect is considered significant. However, the circumstances (such as a high-water event) that would initiate such activity are anticipated to occur infrequently and without much notice. Therefore, certain measures included in the noise control plan environmental commitment discussed in Effect NZ-1 would likely not be feasible. Implementation of Mitigation Measure NZ-MM-2 would reduce this effect to a level of less than significant.

As is discussed above, intermittent noise due to vehicular trips servicing the proposed wells under the relief wells alternative would be relatively infrequent and would not be considered significant. Under the relief wells alternative (Sacramento River South Levee and DWSC East Levee reaches), a pump station would be constructed for permanent operation. With pumps typically generating a noise level in the range of 68 to 80 dBA at a distance of 50 feet (Hoover & Keith 2008), this indicates that noise levels due to a pump station housing one pump could potentially exceed the daytime 50 dBA significance threshold within 700 feet and the 45 dBA nighttime threshold within 1,100 feet. Because residences could be located within this distance, this effect is considered significant. Implementation of Mitigation Measure NZ-MM-3 would reduce this effect to a level of less than significant.

Under the levee raise (in place, adjacent and full), setback levee, stability berm, seepage berm, slope flattening and certain recreation elements (such as trails), maintenance operations may involve the reconditioning of slopes employing the use of dozers and/or the reconditioning of patrol roads employing the use of graders and compactors. Additionally, vegetation removal operations and maintenance may involve the use of hand-powered chainsaws and/or mass grading employing the use if dozers. While these maintenance activities would be relatively infrequent, they would have the potential to exceed the established determinations of effects depending on the distance to the nearest noise-sensitive receptor and the time of day at which said activities were conducted. However, the environmental commitment of implementing a noise control plan outlining noise reduction and maintenance practices to comply with applicable local noise ordinances (as described in Section 2.9 of Chapter 2, Alternatives) would make this effect less than significant.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall	▪ Seepage berm
	▪ Levee raise (in place)	▪ Sheet pile wall
	▪ Levee raise (adjacent)	▪ Slurry cutoff wall
	▪ Levee raise (full)	▪ Slope flattening
	▪ Closure structure	▪ Stability berm
	▪ Interior drain	▪ Rock slope protection
	▪ Jet grouting	▪ Setback levee
	▪ Relief wells	▪ Vegetation removal
Recreation	▪ Trails	▪ Developed water access
	▪ Riverside parks	▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect would occur in all nine program reaches.

Effect NZ-3 Finding	With Mitigation
Significant	Less than significant

Mitigation

Mitigation Measure NZ-MM-2: Employ Noise-Reducing Emergency Operational Practices to Comply with Applicable Local Noise Ordinances Where Feasible

The overseer or contractor in charge of emergency preparedness under the stop- log alternative will prepare a noise control plan identifying feasible measures that will be employed to reduce construction noise where necessary. These measures may include but are not limited to those listed below:

- requiring that construction equipment be equipped with factory-installed muffling devices or better, and that all equipment be operated and maintained in good working order to minimize noise generation;
- employing equipment that is specifically designed for low noise emission levels; and
- employing equipment that is powered by electric or natural gas engines as opposed to those powered by gasoline fuel or diesel.

Mitigation Measure NZ-MM-3: Design Acoustical Treatments into the Proposed Pump Station to Comply with Applicable Local Noise Standards

WSAFCA will design pump stations such that noise does not exceed applicable local noise ordinance standards. Where there is no applicable standard, pump stations will be designed to limit noise to 45 dBA at the nearest residence. Measures that can be incorporated into the station design include but are not limited to:

- maximizing the distance between the pump station and the nearest residence; and
- enclosing the pumps in an enclosed building structure.

Effect NZ-4: Compatibility of Recreation Elements with Surrounding Land Uses

The development of multiple areas of recreation, such as trails, park, kiosks and amphitheatres, is proposed as part of the program. Loud voices and/or amplified public address systems would have the potential to exceed established local noise level standards established for noise sources affecting existing or planned noise-sensitive uses. In addition, park areas where people would congregate and children would potentially play could be located in areas in excess of noise levels established as acceptable by applicable local general plan noise elements. Therefore, this effect is considered significant. However, at the time of preparation of this document, not enough information is available about the location of the specific recreation elements to incorporate adequate mitigation measures. Therefore, this potential significant effect would be addressed at the project-specific level for each of the proposed levee reaches and their respective recreation elements.

Additionally, certain special projects (such as venues for cultural, recreational, educational and/or entertainment activities) are also proposed to be incorporated into the program. At the time of the preparation of this document, project specifics are not available and an analysis of effects would be speculative. These projects would be evaluated individually, each likely necessitating independent environmental documentation and review.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Recreation	▪ Trails	▪ Developed water access
	▪ Riverside parks	▪ Special projects

Affected Reaches

Although different recreation program alternatives are proposed for the reaches, this effect could occur in all nine program reaches.

Effect NZ-4 Finding	With Mitigation
Significant	Determined on a project basis

Effect NZ-5: Exposure of Sensitive Receptors to Temporary Construction-Related Vibration

The operation of heavy equipment may generate groundborne vibration that could be perceptible at residences or other sensitive land uses close to construction activity. Based on vibration reference levels from Federal Transit Administration (2006), vibration from construction activity would attenuate to less than 0.1 in/sec ppv within about 50 feet under typical conditions. Because sensitive receptors in areas of West Sacramento may be located within this distance, this effect is considered to be potentially significant. Implementation of Mitigation Measure NZ-MM-4 may reduce this effect, but not always to a less-than-significant level.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall	▪ Seepage berm
	▪ Levee raise (in place)	▪ Sheet pile wall
	▪ Levee raise (adjacent)	▪ Slurry cutoff wall
	▪ Levee raise (full)	▪ Slope flattening
	▪ Closure structure	▪ Stability berm
	▪ Interior drain	▪ Rock slope protection
	▪ Jet grouting	▪ Setback levee
	▪ Relief wells	▪ Vegetation removal
Recreation	▪ Trails	▪ Developed water access
	▪ Riverside parks	▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect could occur in all nine program reaches.

Effect NZ-5 Finding	With Mitigation
Significant	Less than significant – Significant and unavoidable

Mitigation

Mitigation Measure NZ-MM-4: Employ Measures to Prevent Excessive Exposure of Buildings and Structures to Groundborne Vibration

WSAFCA or its contractor will, to the extent feasible, maintain a minimum distance of 50 feet between construction equipment and occupied or vibration-sensitive buildings or structures. For cases where this is not feasible, the resident or property owner will be notified in writing prior to construction activity, and where necessary, relocated to temporary housing for the duration of construction activity. WSAFCA will inspect the interior walls of those homes prior to construction to inventory existing cracks in paint and plaster and will retain a qualified acoustical consultant or engineering firm to conduct vibration monitoring at that building to measure the actual vibration levels during construction. Following completion of construction, WSAFCA will conduct a second inspection to inventory new damage to paint and plaster, if any, that occurred as a result of construction-induced vibration. If new damage is found, then WSAFCA will promptly arrange to have the damaged repaired, or will reimburse the property owner for appropriate repairs.

In addition, if construction activity is required within 100 feet of residences or other vibration-sensitive buildings, a designated complaint coordinator will be responsible for handling and responding to any complaints received during such periods of construction. A reporting program will be required that documents complaints received, actions taken, and the effectiveness of these actions in resolving disputes.

Section 3.8
Vegetation and Wetlands

3.8.1 Introduction

This section describes the regulatory and environmental setting for vegetation and wetlands, effects on vegetation and wetlands that would result from the program, and mitigation measures that would reduce significant effects.

The key sources of data and information used in the preparation of this section are listed below.

- California Natural Diversity Database (CNDDB) records search of the USGS 7.5-minute Grays Bend, Taylor Monument, Rio Linda, Davis, Sacramento West, Sacramento East, Dixon, Saxon, Clarksburg, Florin, Dozier, Liberty Island, Courtland, Birds Landing, Rio Vista, and Isleton quadrangles (California Natural Diversity Database 2009)
- USFWS list of endangered, threatened, and proposed for listing species for the USGS 7.5-minute Sacramento West, Clarksburg, Saxon, Liberty Island, and Rio Vista quadrangles and Yolo and Solano Counties obtained from the USFWS website (U.S. Fish and Wildlife Service 2009)
- California Native Plant Society's (CNPS's) 2009 online Inventory of Rare and Endangered Plants (California Native Plant Society 2009a)
- Vegetation data from the Yolo Natural Heritage Program (Yolo Natural Heritage Program 2009)
- Aerial photographs of the program study area
- *Yolo County General Plan* (Yolo County 2002)
- *City of West Sacramento General Plan Policy Document* (City of West Sacramento 2004)
- *Yolo County Oak Woodland Conservation and Enhancement Plan* (Yolo County 2007)

An ICF International biologist conducted prefield and reconnaissance-level field surveys in the study area, as further described in the Environmental Consequences section below. This information was used to develop lists of special-status plant species and sensitive natural communities that could be present in the study area. Special-status species with potential to occur in the study area are discussed in the Environmental Setting section below.

3.8.2 Affected Environment

3.8.2.1 Regulatory Setting

3.8.2.1.1 Federal

Endangered Species Act

USFWS and NMFS are responsible for implementation of the Federal ESA (16 USC 1531 *et seq*.). The ESA protects fish and wildlife species that are listed as threatened or endangered, as well as their

habitats. *Endangered* species, subspecies, or distinct population segments are in danger of extinction through all or a significant portion of their range. *Threatened* species, subspecies, or distinct population segments are likely to become endangered in the near future.

ESA Section 7 mandates that all Federal agencies consult with USFWS and NMFS if the agencies determine that a proposed project may affect a listed species or its habitat. The purpose of consultation with USFWS and NMFS is to ensure that the Federal agencies' actions do not jeopardize the continued existence of a listed species or destroy or significantly modify any critical habitat for listed species.

For plants listed as endangered under the ESA, Section 9(a)(2) of the act prohibits their import or export from the United States. Section 9(a)(2) also prohibits acts to remove, cut, dig up, damage, or destroy endangered plant species in non-Federal areas in knowing violation of any state law or in the course of criminal trespass. Candidate species and species that are proposed or under petition for listing receive no protection under Section 9.

Clean Water Act

The Federal CWA is administered by the EPA and USACE. USACE is responsible for regulating the discharge of fill material into waters of the United States (including lakes, rivers, streams, and their tributaries) and wetlands. Wetlands are defined for regulatory purposes as areas that are "inundated or saturated by surface or ground water at a frequency and duration sufficient to support, and that under normal circumstances, do support a prevalence of vegetation typically adapted for life in saturated soil conditions"(Environmental Laboratory 1987: 13).

The discharge of dredged or fill material into waters of the United States is subject to permitting under CWA Section 404. Certification from the applicable RWQCB is also required when a proposed activity may result in discharge into navigable waters, pursuant to CWA Section 401 and EPA's Section 404(b)(1) guidelines.

USACE and EPA recently developed a memorandum titled Clean Water Act Jurisdiction Following the U.S. Supreme Court's Decision in *Rapanos* v. *United States & Carabell* v. *United States* that states that the agencies will assert jurisdiction over the following categories of water bodies: traditional navigable waters (TNWs), wetlands adjacent to TNWs, non-navigable tributaries of TNWs that are relatively permanent, and wetlands that abut such tributaries.

Additionally, the Sacramento District of USACE recently issued a public notice (SPK-2008-01557) regarding local processing procedures for jurisdictional determinations. Applicants seeking USACE permits can elect either the traditional "approved" approach to obtain a jurisdictional determination from USACE or seek a preliminary jurisdictional determination that concedes jurisdiction to USACE. The preliminary jurisdictional determination is intended to streamline the process for applicants who want to obtain USACE permit authorizations or jurisdictional determinations.

Rivers and Harbors Act

Rivers and Harbors Act Section 10 requires authorization from USACE for the construction of any structure in or over any navigable waters of the United States. Tidal waterways within the Delta are considered navigable waters. The law applies to any dredging, excavation, filling, or other modification of a navigable water of the United States, as well as to all structures, including bank protection (e.g., riprap) and mooring structures, such as those in a marina. Structures or work

outside the limits defined for navigable waters of the United States require a Section 10 permit if the structure or work would affect the course, location, or condition of the water body.

Executive Order 11990: Protection of Wetlands

Executive Order 11990, signed May 24, 1977, directs all Federal agencies to refrain from assisting in or giving financial support to projects that encroach on publicly or privately owned wetlands. It further requires that Federal agencies support a policy to minimize the destruction, loss, or degradation of wetlands. A project that encroaches on wetlands may not be undertaken unless the agency has determined that 1) there are no practicable alternatives to such construction, 2) the project includes all practicable measures to minimize harm to wetlands that would be affected by the project, and 3) the effect would be minor.

Executive Order 13112: Invasive Species

Executive Order 13112, signed February 3, 1999, directs all Federal agencies to prevent and control the introduction of invasive species in a cost-effective and environmentally sound manner. The order established the National Invasive Species Council, which is composed of Federal agencies and departments, and the supporting Invasive Species Advisory Committee, which is composed of state, local, and private entities. The council's national invasive species management plan recommends objectives and measures to implement Executive Order 13112 and to prevent the introduction and spread of invasive species (National Invasive Species Council 2008). Executive Order 13112 requires consideration of invasive species in NEPA analyses, including their identification and distribution, their potential effects, and measures to prevent or eradicate them.

3.8.2.1.2 State

The state laws that regulate the treatment of vegetation and wetlands in the program area are outlined below

California Endangered Species Act

The California Endangered Species Act (CESA) was enacted in 1984. The act prohibits the take of endangered, threatened, and candidate species and defines it as an activity that would directly or indirectly kill an individual of a species; habitat destruction is not included in the state's definition of take. Section 2090 of CESA requires state agencies to comply with endangered species protection and recovery and to promote conservation of these species. DFG administers the act and authorizes take through Section 2081 agreements (except for species designated as fully protected). DFG can adopt a Federal biological opinion as a state biological opinion under California Fish and Game Code, Section 2095. In addition, DFG can write a consistency determination for species that are both federally and state-listed if DFG determines that the avoidance, minimization, and compensation measures will ensure no take of species. In the case of rare plant species, CESA defers to the California Native Plant Protection Act of 1977 (CNPPA; discussed below).

California Native Plant Protection Act

The CNPPA prohibits importation of rare and endangered plants into California, and take or sale of rare and endangered plants. CESA defers to CNPPA, which ensures that state-listed plant species are protected when state agencies are involved in projects subject to CEQA. In this case, plants listed as rare under CNPPA are not protected under CESA, but rather under CEQA.

California Fish and Game Code

DFG provides protection from take for a variety of species under the California Fish and Game Code. DFG also protects streams, water bodies, and riparian corridors through the streambed alteration agreement process under Fish and Game Code 1601–1606. The code stipulates that it is "unlawful to substantially divert or obstruct the natural flow or substantially change the bed, channel or bank of any river, stream or lake" without notifying DFG, incorporating necessary mitigation, and obtaining a streambed alteration agreement. DFG's jurisdiction extends to the top of banks and often includes the outer edge of riparian vegetation canopy cover. Riparian trees that have a diameter of 6 inches or greater also fall within DFG's jurisdiction.

Porter-Cologne Water Quality Control Act

Section 13260 of the California Water Code requires "any person discharging waste, or proposing to discharge waste, in any region that could affect the *waters of the state* to file a report of discharge (an application for waste discharge requirements)." Under the Porter-Cologne Water Quality Control Act definition, the term *waters of the state* is defined as "any surface water or groundwater, including saline waters, within the boundaries of the state." Although all waters of the United States that are within the borders of California are also waters of the state, the converse is not true—in California, waters of the United States represent a subset of waters of the state. Therefore, the State of California retains authority to regulate discharges of waste into any waters of the state, regardless of whether USACE has concurrent jurisdiction under CWA Section 404.

If USACE determines a wetland is not subject to regulation under CWA Section 404, water quality certification under CWA Section 401 is not required. However, the RWQCB may impose waste discharge requirements (WDRs) if fill material would be placed into waters of the state.

3.8.2.1.3 Local

Yolo County

Yolo County General Plan

Table 3.8-1 summarizes the *Yolo County General Plan* policies (Yolo County 2002) related to vegetation and wetlands in the program area.

Yolo County Oak Woodland Conservation and Enhancement Plan

The *Yolo County Oak Woodland Conservation and Enhancement Plan* (Yolo County 2007) promotes voluntary efforts to conserve and enhance the county's existing oak woodlands to help minimize the effects of land conversion and other factors that disturb the health and longevity of existing oak woodlands.

Table 3.8-1. Summary of Yolo County General Plan Policies Related to Vegetation and Wetlands in the Program Area

Policy Number	Policy Description
OP-4	The County shall encourage and support coordinated efforts by State and federal agencies, cities, special districts, and non-profit and conservation organizations to protect lands containing open space resources.
OP-5	The County shall utilize the CEQA process to identify significant impacts on open space and shall require new development to implement county-approved mitigation measures that minimize such impacts.
OP-6	The County shall utilize the following objective criteria when considering conversion of open space lands to other uses: • The use is directly related and essential to an otherwise approved open space, agricultural or recreational activity; • Lack of suitable locations in Yolo County prevent the use from locating within an area not designated for open space uses; • The site is not located in a conservation easement, contracted agricultural preserve, Farmland Security Zone, flood control bypass or channel, or earthquake fault zone; • The use will not diminish or prevent open space, recreational or agricultural use on adjoining lands; • The use can be developed without impairing the open space experience, managed resource production and other open space uses and activities in the vicinity; and • The use does not conflict with any adopted local, State or federal plans for protection of open space resources.
OP-7	Development shall be directed away from naturally occurring riparian areas and wetlands.
OP-8	Open space buffer areas shall be utilized to separate incompatible uses from areas of unique biological or agricultural importance.
OP-18	The County, in conjunction with the cities in Yolo County, shall endeavor to adopt a Natural Communities Conservation Plan that protects wildlife resources, open space and agricultural production.

Source: Yolo County 2002.

City of West Sacramento

City of West Sacramento General Plan

Table 3.8-2 summarizes the *City of West Sacramento General Plan* policies (Part II, Section 6) (City of West Sacramento 2004) that are applicable to vegetation and wetlands in the program area.

Table 3.8-2. Summary of City of West Sacramento General Plan Policies Related to Vegetation and Wetland Resources in the Program Area

Section-Goal-Policy Number	Policy Description
VI-C-1	The City shall encourage and support development projects and programs that enhance public appreciation and awareness of the natural environment.
VI-C-2	The City shall support state and federal policies for preservation and enhancement of riparian and wetland habitats by incorporating, as deemed appropriate, the findings and recommendations of the *Sacramento Greenway Plan*, California Department of Fish and Game and the U.S. Fish and Wildlife Service into site-specific development proposals.
VI-C-3	The City shall require site-specific surveys to identify significant wildlife habitat and vegetation resources for development projects located in or near riparian or wetland areas.
VI-C-4	The City shall support mitigation measures which provide for no net loss of riparian or wetland habitat acreage and value by regulating development in and near these habitats and promoting projects that avoid sensitive areas. Where habitat loss is unavoidable, the City shall seek replacement on at least a 1:1 basis. Replacement entails creating habitat that is similar in extent and ecological value to that displaced by the project. The replacement habitat should consist of locally occurring, native species and shall be located as close as possible to the project site or be part of a larger replacement habitat project.
VI-C-5	To minimize disturbance to wildlife, the City shall require the provision and maintenance of an adequate setback between significant wetland habitat and adjacent development. The buffer shall be landscaped with native or compatible introduced ornamental vegetation and may be used for passive recreation purposes.
VI-C-6	The City shall encourage the maintenance of marsh and riparian vegetation along irrigation/drainage canals and along the Deep Water Ship Channel by encouraging that routine maintenance and clearing disturb only one bank per year and maintain the fringes of marsh vegetation.
VI-C-7	The City shall seek to minimize the loss or degradation of wetland and riparian habitats at the following sites: Lake Washington and associated wetlands; Bee Lakes and associated riparian woodlands; riparian woodlands along the Sacramento River north of the I Street Bridge and south of the barge canal; and riparian woodlands along the Deep Water Ship Channel and the Yolo Bypass.
VI-C-9	The City shall seek to preserve populations of rare, threatened, and endangered species by ensuring that development does not adversely affect such species or by fully mitigating adverse effects.
VI-C-10	The City shall not approve projects that would affect endangered wildlife or plant species.
VI-C-11	The City shall implement measures to ensure that development in the city does not adversely affect fishery resources in the Sacramento River, Deep Water Ship Channel, and Lake Washington.
VI-C-12	Public access and recreation facilities shall not eliminate or degrade riparian habitat values. Trails, picnic areas, and other developments shall be sited to minimize impacts on sensitive wildlife habitat or riparian vegetation.
VI-C-13	The City shall promote the use of native plants, especially valley oaks, for landscaping roadsides, parks, and private properties. In particular, native plants should be used along the Sacramento River and in areas adjacent to riparian and wetland habitats.

Source: City of West Sacramento 2004.

Tree Preservation Ordinance

The City's Tree Preservation Ordinance is found in the West Sacramento Municipal Code, Title 8 (Health and Safety), Chapter 24 (Tree Preservation). The City has definitions for heritage and landmark trees. Trees that may be considered landmark or heritage trees occur in the program area.

A *heritage tree* is defined as any living tree with a trunk circumference of 75 inches (diameter of 24 inches) or more, or any living native oak (any species of the genus *Quercus*) with a trunk circumference of 50 inches (diameter of 16 inches) or more, both measured 4.5 feet above ground level. The circumference of multi-trunk trees is based on the sum of the circumference of each trunk. A *landmark tree* is defined as a tree or stand of trees that is especially prominent, stately, or of historical significance as designated by the City Council. Trees that are too small in diameter to meet the size threshold of either a heritage or landmark tree but are located within the public right-of-way (typically 12.5 feet from the curb) are also protected by the ordinance.

It is unlawful in West Sacramento to perform any of the following acts with respect to a heritage or landmark tree without a tree permit issued by the City's tree administrator:

- Move, remove, cut down, poison, set fire to or permit fire to burn in proximity to, or perform or fail to perform any act that results in the unnatural death or destruction of a landmark or heritage tree.
- Perform any activity that will interfere with or retard the natural growth of any landmark or heritage tree.
- Perform any work or permit any work to be performed within the dripline area of a landmark or heritage tree.
- Trim or prune any branch of a landmark or heritage tree that is 5 inches or more in diameter.
- Change the appropriate amount of irrigation or drainage water provided to any landmark, heritage, or street tree. Trench, grade, pave, or otherwise damage or disturb any exposed roots within 1 foot outside the dripline area of any landmark, heritage, or street tree.
- Park or operate any motor vehicle within 1 foot outside the dripline area of any landmark, heritage, or street tree.
- Place or store any equipment or construction materials within 1 foot outside the dripline area of any landmark, heritage, or street tree.
- Place, apply, or attach any signs, ropes, cables, or other items to any landmark, heritage, or street tree.
- Place or allow to flow any oil, fuel, concrete mix, or other deleterious substance into or over within 1 foot outside the dripline area of any landmark, heritage, or street tree.

Tree permits require the applicant to replace a tree that must be removed with a living tree on the property or within West Sacramento in a location approved by the tree administrator. The applicant must also replace the replacement tree if it dies any time within 3 years of the initial planting. Replacement is not required if a tree is removed because it poses a risk or hosts a plant parasite.

Replacement trees are required at a ratio of 1:1 (i.e., 1-inch diameter of replacement plant for every 1-inch diameter of tree removed). Replacement trees may be a combination of 15-gallon trees, which are the equivalent of a 1-inch-diameter tree, or 24-inch box trees, which are the equivalent of

a 3-inch-diameter tree. If trees cannot be replaced on site, the applicant must pay an in-lieu fee, which will be used to purchase and plant trees elsewhere in West Sacramento.

Solano County

The general plan was adopted by the Board of Supervisors on August 5, 2008. The general plan contains a resources element that strives to ensure conservation, preservation, and enhancement of natural, cultural, and open space resources to ensure a high quality of life for current and future county residents. The resources chapter of the general plan identifies the following goals, policies, and implementation measures associated with natural (biological) resources that will be used by Solano County in day-to-day decision making to protect these resources.

General Resource Goals

The goals and accompanying policies describe outcomes consistent with the following strategic directions of the general plan:

- preserving of the county's valued natural, cultural, and scenic resources;
- enhancing and restoring the natural environment and the county's diverse landscapes; and
- ensuring sustainable provision of energy, water, and mineral resources.

General Resource Policies

- **RS.G-1:** Manage and preserve the diverse land, water, and air resources of the county for the use and enrichment of the lives of present and future generations.
- **RS.G-2:** Ensure continued presence and viability of the county's various natural resources.
- **RS.G-3:** Repair environmental degradation that has occurred, and seek an optimum balance between the economic and social benefits of the county's natural resources.
- **RS.G-4:** Preserve, conserve, and enhance valuable open space lands that provide wildlife habitat; conserve natural and visual resources; convey cultural identity; and improve public safety.
- **RS.G-5:** Ensure availability of affordable energy supplies and require efficiency and conservation measures to minimize energy consumption.
- **RS.G-6:** Preserve the visual character and identity of communities by maintaining open space areas between them.
- **RS.G-7:** Ensure provision of an adequate, competitively priced and sustainable water supply and associated infrastructure to serve the needs of existing and future water users.
- **RS.G-8:** Achieve ongoing coordination between land use and water supply planning.
- **RS.G-9:** Protect, monitor, restore and enhance the quality of surface and groundwater resources to meet the needs of all beneficial uses.
- **RS.G-10:** Foster sound management of the land and water resources in Solano County's watersheds to minimize erosion and protect water quality using best management practices and protect downstream waterways and wetlands.

Biological Resource Policies

- **RS.P-1:** Protect and enhance the county's natural habitats and diverse plant and animal communities, particularly occurrences of special-status species, wetlands, sensitive natural communities, and habitat connections.
- **RS.P-2:** Manage the habitat found in natural areas and ensure its ecological health and ability to sustain diverse flora and fauna.
- **RS.P-3:** Focus conservation and protection efforts on high –priority habitat areas.
- **RS.P-4:** Together with property owners and Federal and state agencies, identify feasible and economically viable methods of protecting and enhancing natural habitats and biological resources.
- **RS.P-5:** Protect and enhance wildlife movement corridors to ensure the health and long-term survival of local animal and plant populations. Preserve contiguous habitat areas to increase habitat value and to lower land management costs.
- **RS.P-6:** Protect oak woodlands and heritage trees and encourage the planting of native tree species in new developments and along road rights-of-way.

3.8.2.2 Environmental Setting

This section defines the study area evaluated for vegetation and wetland resources, identifies waters of the United States (including wetlands) preliminarily mapped in the study area, and describes existing land cover types in the study area. Land cover types are shown in Figure 3.8-1, and wetlands and waters of the United States are outlined in Figure 3.8-2. This section also discusses special-status plant species that are known to occur in the program region, invasive plant species, and protected tree resources.

3.8.2.2.1 Study Area

The program area is located along the reaches of the following levees:

- Sacramento River North Levee
- Sacramento River South Levee
- Port North Levee
- Port South Levee
- South Cross Levee
- DWSC West Levee
- DWSC East Levee
- Yolo Bypass Levee
- Sacramento Bypass Levee

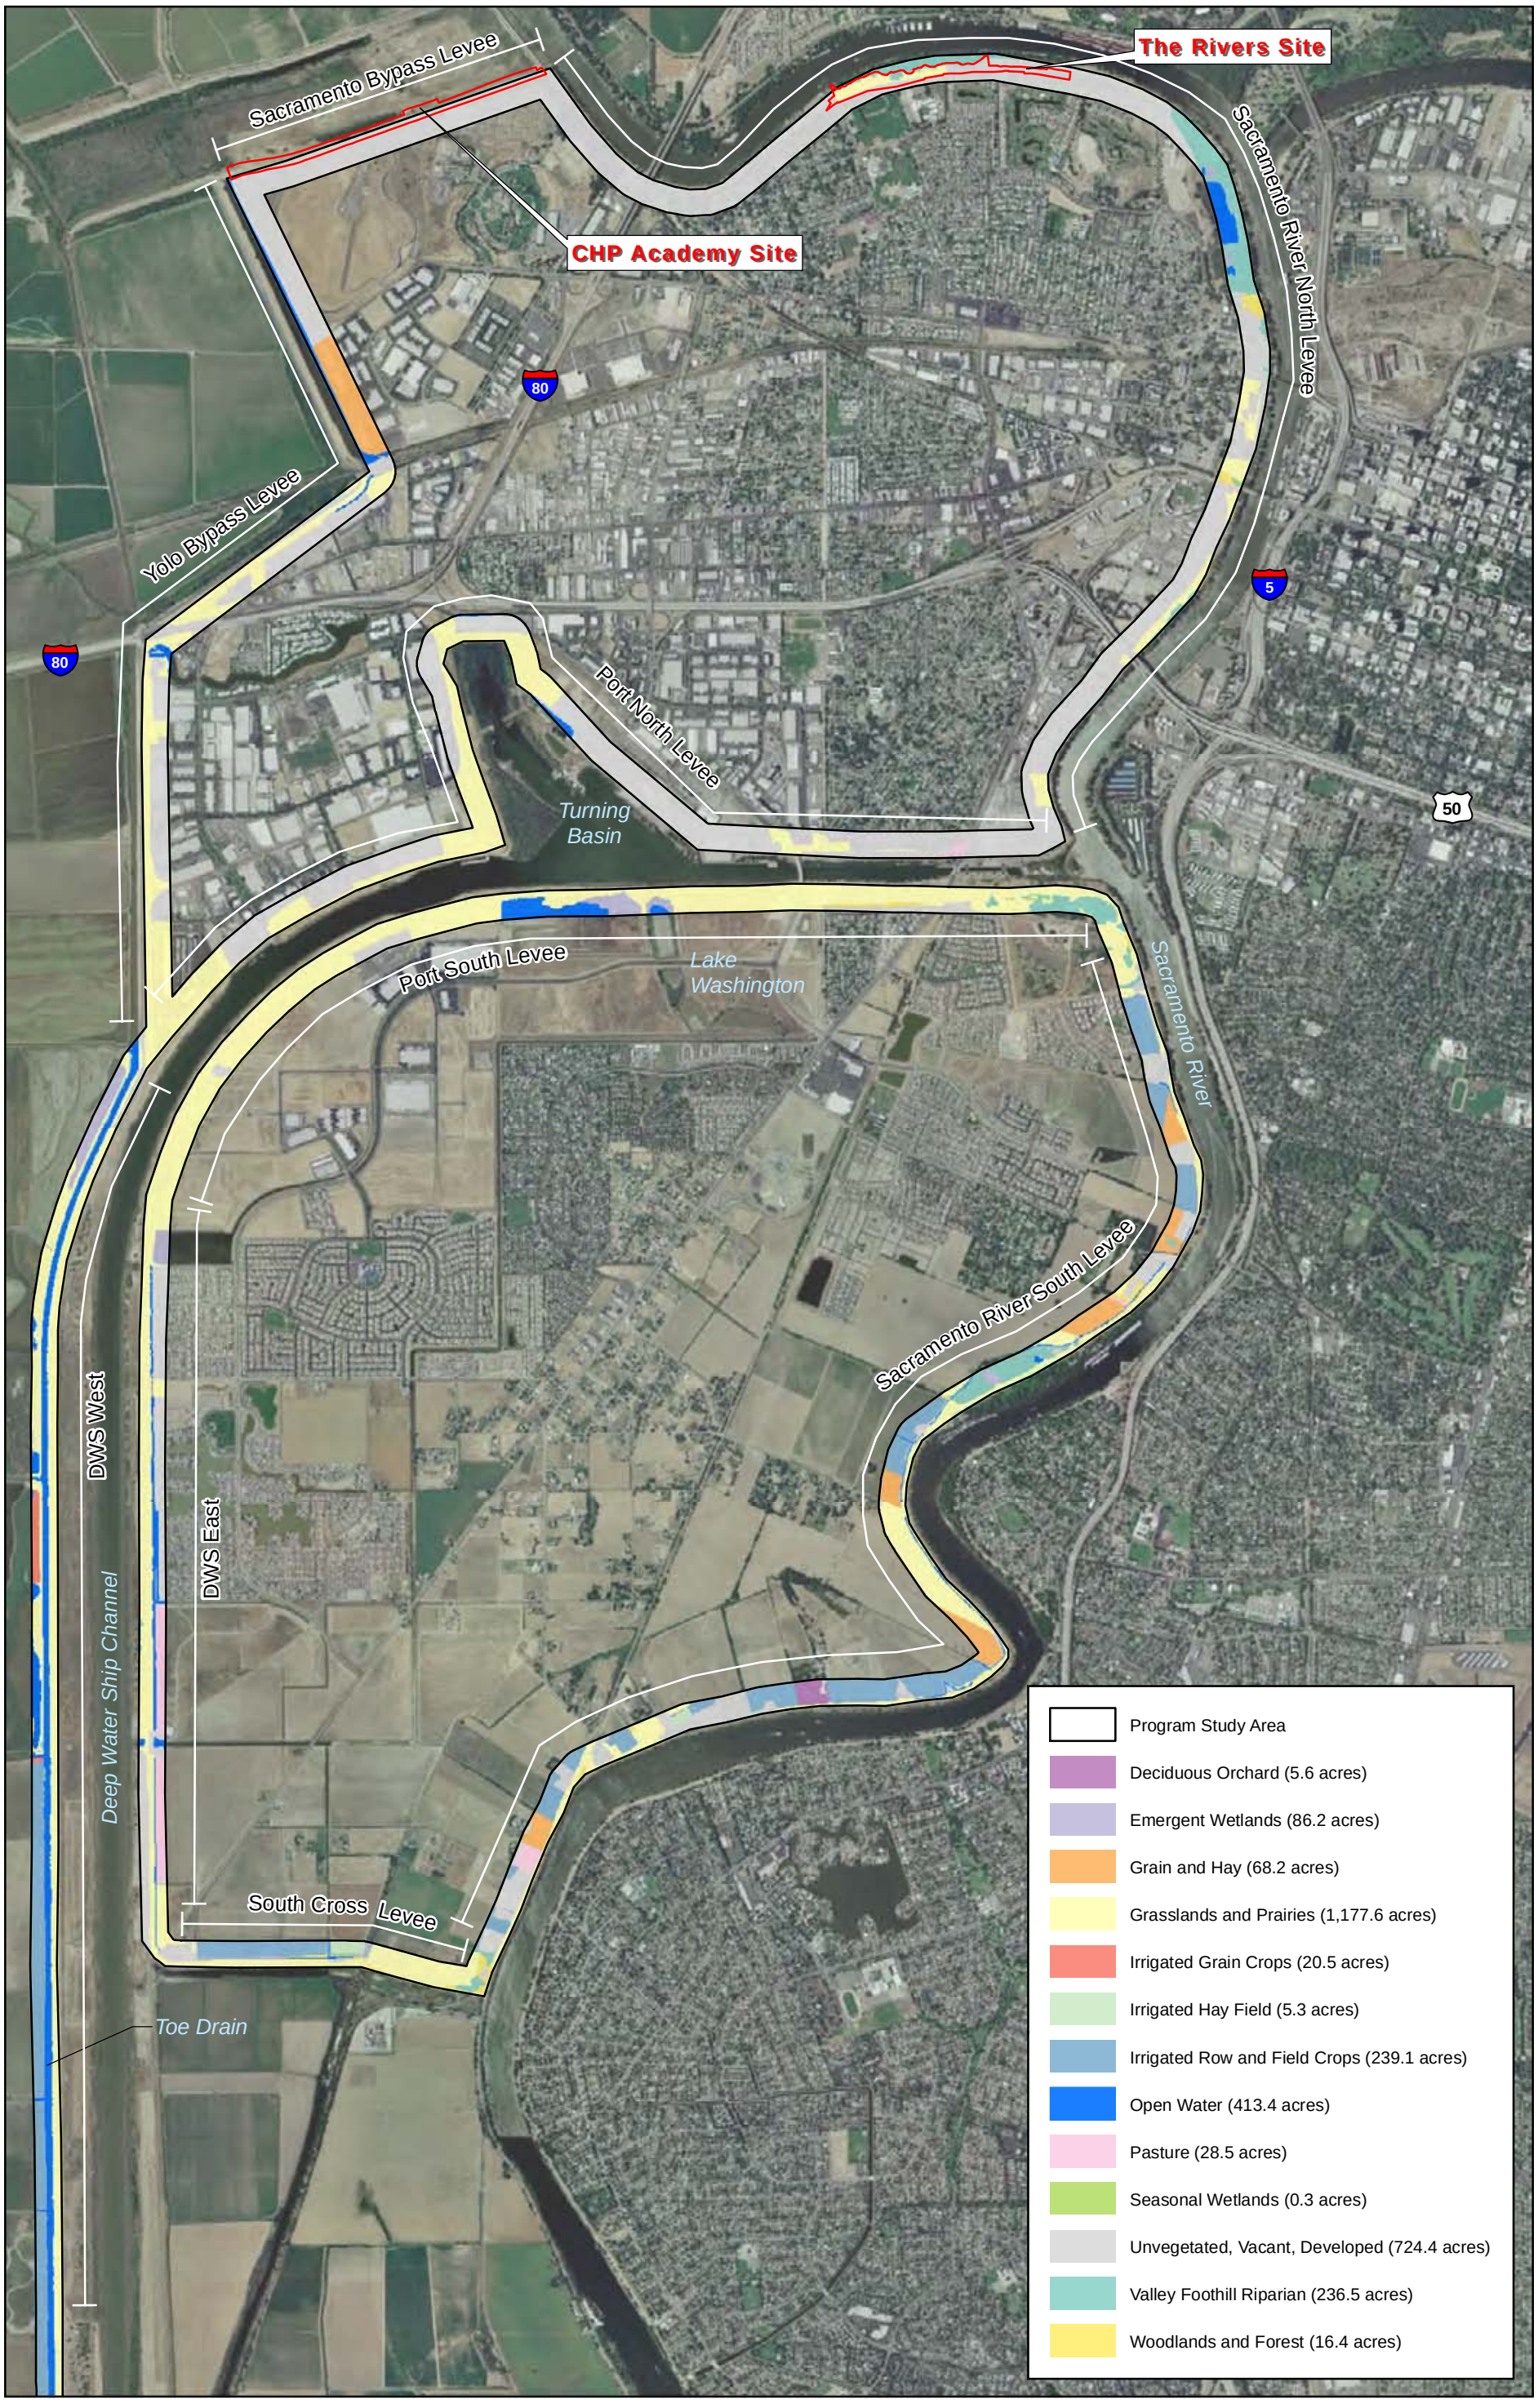
For the purposes of this program-level analysis, the study area consists of program area plus an approximate 500-foot-wide buffer area on the landside of each of the levee reaches. The study area is located within the Great Central Valley subdivision of the California Floristic Province in Yolo

County (Hickman 1993: 44, 45) and the elevation in the study area ranges from about 10 to 35 feet above mean sea level.

3.8.2.2.2 Prefield Investigation

Prior to the reconnaissance-level field visits, the botanist/wetland ecologist reviewed the following sources of information pertaining to vegetation and wetland resources in the study area:

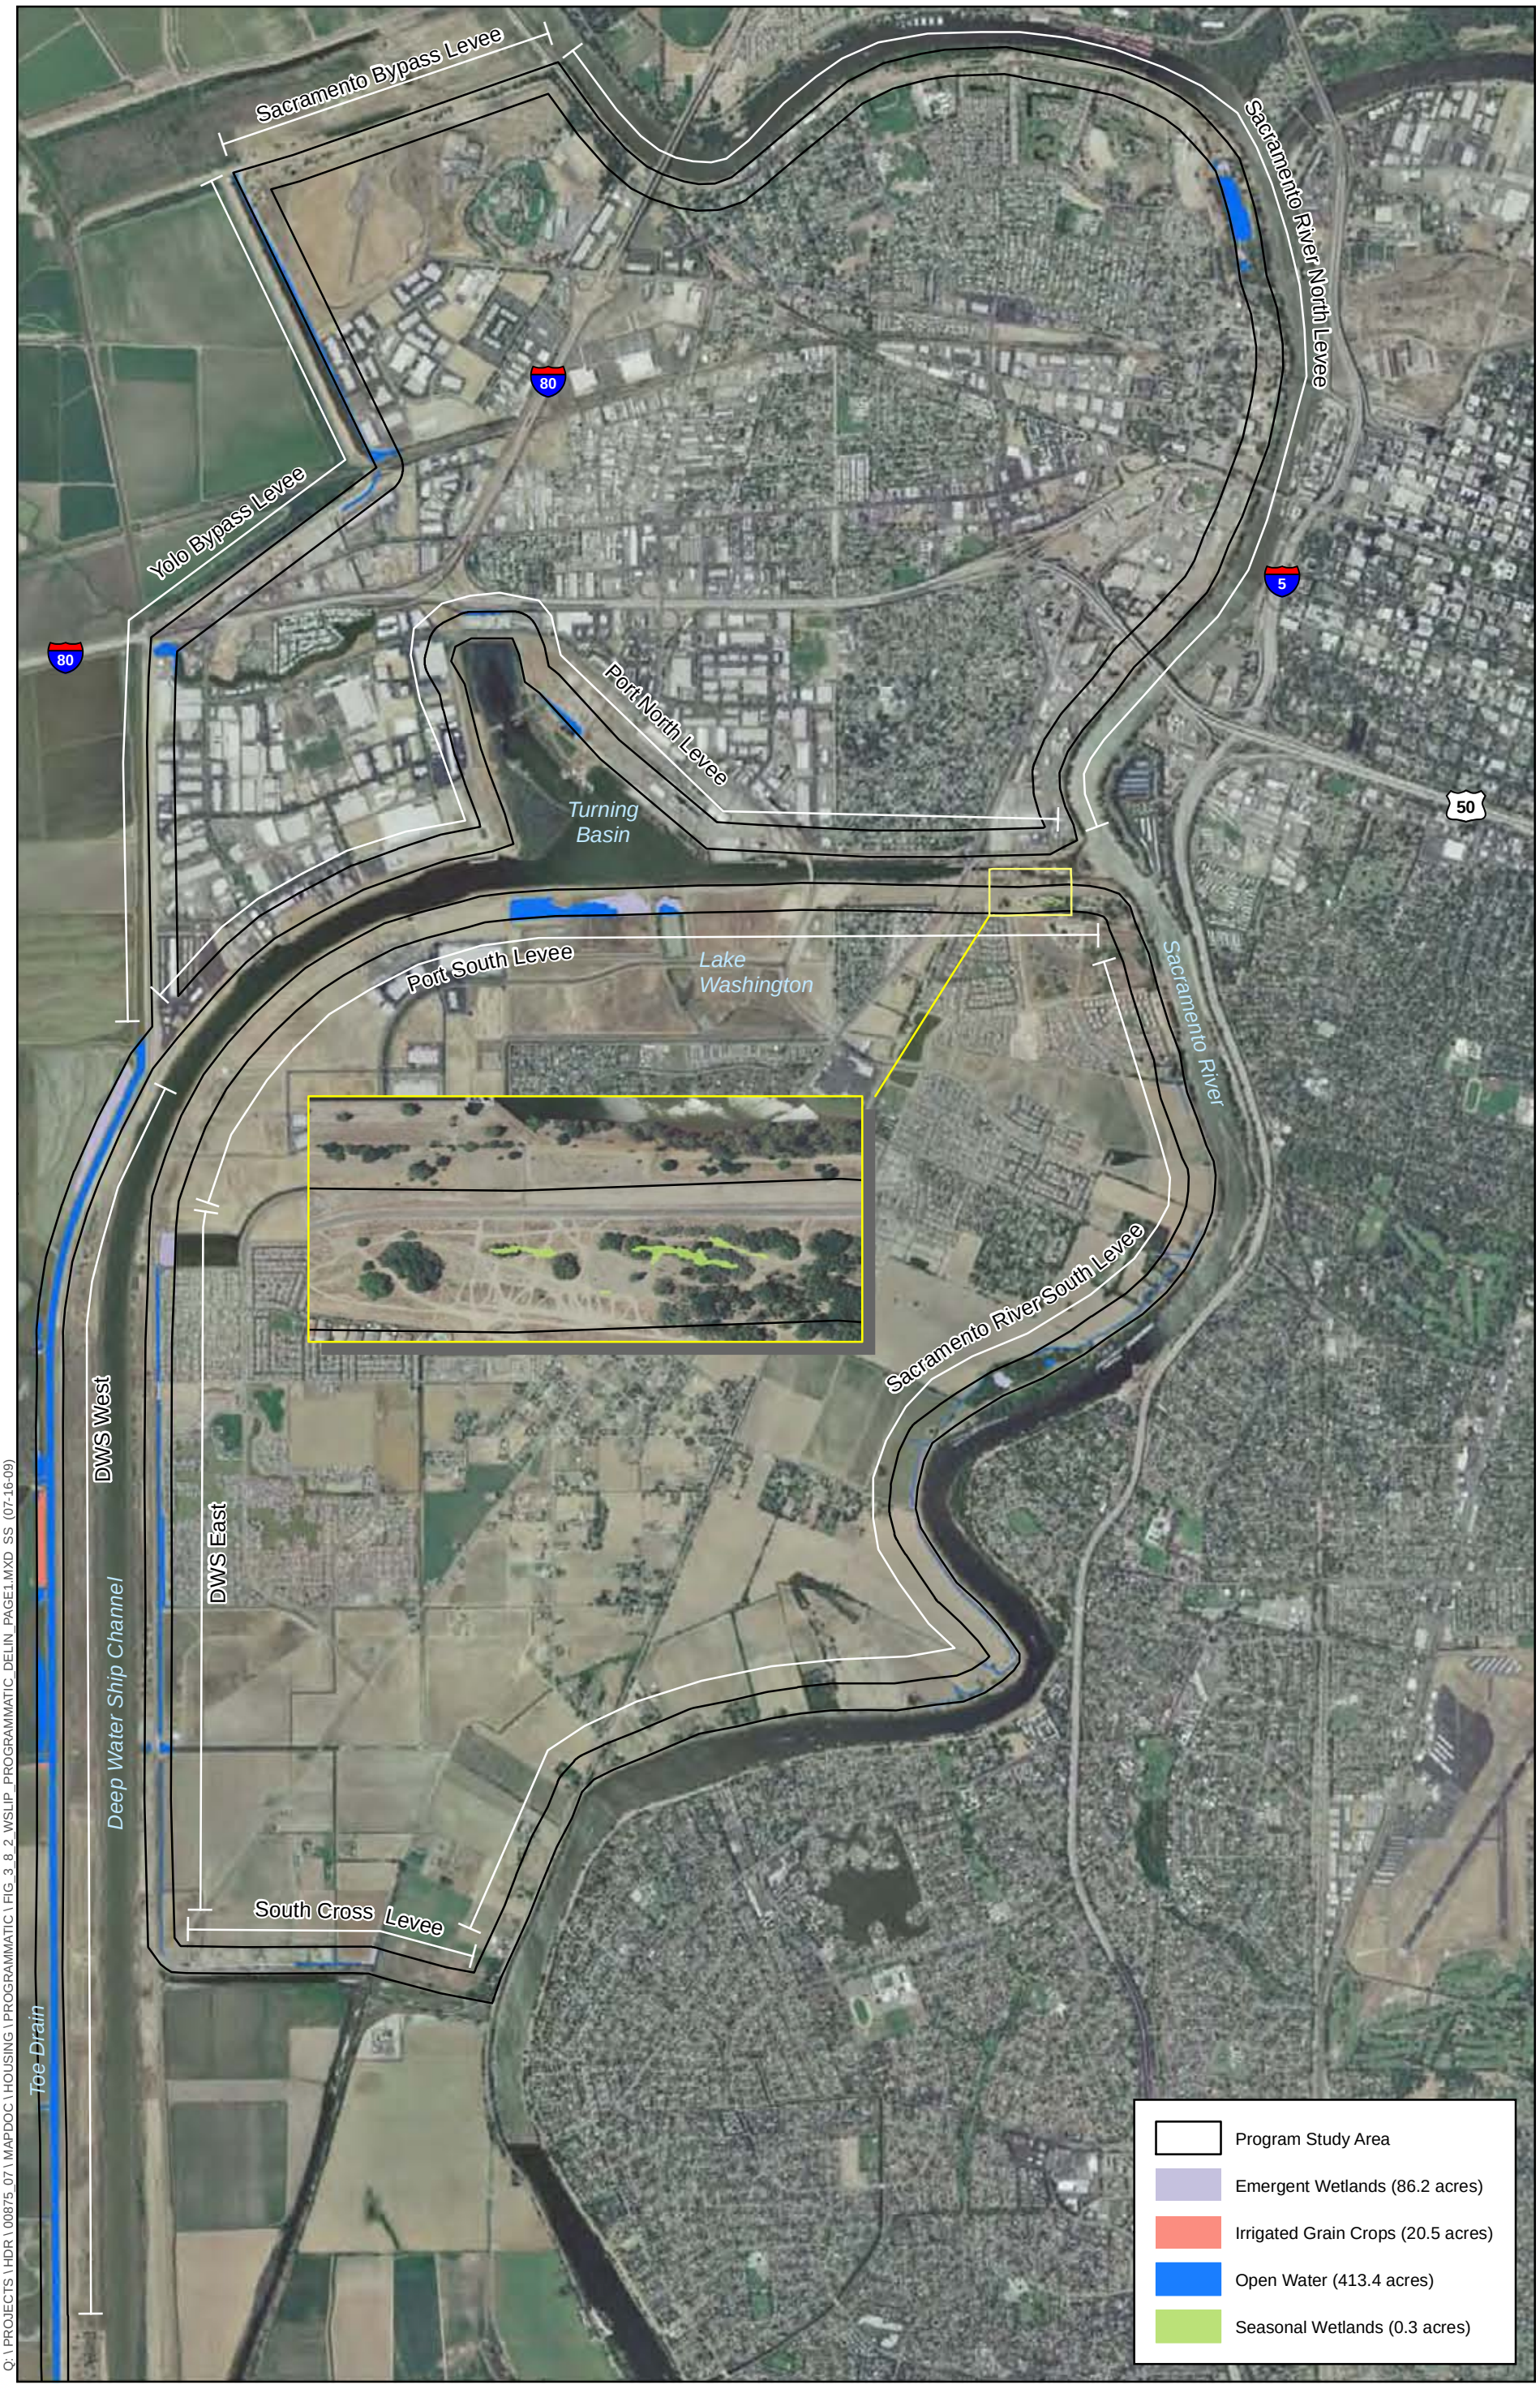
- a CNDDB records search of the USGS 7.5-minute Sacramento West, Sacramento East, Grays Bend, Taylor Monument, Rio Linda, Davis, Clarksburg, Saxon, and Florin quadrangles (California Natural Diversity Database 2007);
- the USFWS list of endangered, threatened, and species proposed for listing for the USGS 7.5-minute Sacramento West quadrangle and Yolo County obtained from the USFWS website (U.S. Fish and Wildlife Service 2007);
- the CNPS's 2007 online Inventory of Rare and Endangered Plants (California Native Plant Society 2007); and
- aerial photographs of the program study area.



3.8.2.2.3 Field Surveys

The evaluation of potential program effects on vegetation and wetlands is based on the results of field surveys and a review of existing documentation. An ICF International botanist/wetland ecologist conducted reconnaissance-level field visits to various portions of the study area on June 21, September 19, October 5, and November 29, 2007; December 18 and 19, 2008; and January 9, 2009. In general, the field visits were conducted to:

- identify land cover types and verify existing vegetation data,
- evaluate whether potential habitat may be present for special-status plant species that have been identified in the vicinity of the study area, and
- identify potential waters of the United States (including wetlands).



3.8.2.2.4 Waters of the United States, Including Wetlands

The study area contains numerous features that are or have the potential to be waters of the United States, including wetlands. For the purposes of this program analysis, the approximate locations and acreages of wetlands and other waters in the study area were identified using a combination of vegetation data from the Yolo Natural Heritage Program, aerial photograph interpretation, and field observations. The land cover types that represent wetlands and other waters in the study area are shown in Figure 3.8-2 and include emergent wetlands (approximately 86 acres), irrigated grain crops (approximately 20 acres), open water (approximately 413 acres), and seasonal wetlands (0.3 acre). The study area may contain additional wetlands and other waters that would be identified as part of project-level analyses. The Sacramento River, DWSC, and Turning Basin are TNWs, and therefore subject to regulations by USACE and EPA under the CWA. The marshes and areas of open water in the study area that are located adjacent to these TNWs are also considered jurisdictional. The drainages located at the toe of the levee (i.e., toe drains) and adjacent to agricultural fields are potentially jurisdictional areas.

3.8.2.2.5 Land Cover Types

Vegetation information for most of the study area was obtained from the Yolo Natural Heritage Program's Vegetation Map Series (Yolo Natural Heritage Program 2009). The land cover types discussed below are based on categories established by the Yolo Natural Heritage Program. The vegetation information obtained was field-verified at accessible areas within the study area. A combination of aerial photograph interpretation and field observation was used to identify land cover types in the remainder of the study area.

Based on this information, it was determined that numerous land cover types occur in the study area. Five are considered natural communities: valley foothill riparian habitat, grasslands and prairies, emergent wetlands, woodlands and forest, and open water. The others are associated with human activities: pasture, grain and hay fields; deciduous orchards; irrigated hay fields; irrigated row and field crops; and unvegetated, vacant, or developed areas. A list of all plant species observed during reconnaissance-level field visits to the study area is provided in Appendix F. Each land cover type is discussed below and shown in Figure 3.8-1.

Natural Communities

Valley Foothill Riparian Habitat

Most valley foothill riparian habitat in the study area (hereafter referred to as "riparian habitat") occurs along the Sacramento River North and Sacramento River South Levees, but smaller riparian areas are found at all of the levees in the study area (Figure 3.8-1).The total area encompassed by valley foothill riparian habitat in the study area is approximately 239 acres. The overstory of the riparian habitat consists of mature, well-established trees: Fremont cottonwood (*Populus fremontii* ssp*. fremontii*), valley oak (*Quercus lobata*), black willow (*Salix gooddingii*), and box elder (*Acer negundo* var. *californicum*). During the reconnaissance-level field visits, Oregon ash (*Fraxinus latifolia*), western sycamore (*Platanus racemosa*), and white alder (*Alnus rhombifolia*) were also observed. The shrub layer consists of smaller trees and shrubs; representative species observed were poison oak (*Toxicodendron diversilobum*), sandbar willow (*Salix exigua*), and Himalayan blackberry (*Rubus discolor*). The riparian habitat in the study area also contains trees that may be considered heritage or landmark trees as defined by the City. Elderberry shrubs (*Sambucus mexicana*), the host plant of the valley elderberry longhorn beetle (*Desmocerus californicus dimorphus*), which is federally listed as threatened, were observed in the riparian habitat. Riparian habitat is listed as a sensitive natural community by the CNDDB (2009).

Grasslands and Prairies

Grasslands and prairies consisting of non-native annual grassland cover approximately half of the study area and encompass a total of approximately 1,178 acres (Figure 3.8-1). The largest non-native annual grassland area occurs near the DWSC East, Port South, and DWSC West Levees, but grasslands are scattered throughout the study area. The non-native annual grassland is dominated by naturalized annual grasses with intermixed perennial and annual forbs. Grasses commonly observed in the study area are foxtail barley (*Hordeum murinum* ssp. *leporinum*), ripgut brome (*Bromus diandrus*), Italian ryegrass (*Lolium multiflorum*), and soft chess (*Bromus hordeaceus*). Other grasses observed were wild oats (*Avena* spp.), Bermuda grass (*Cynodon dactylon*), and rattail fescue (*Vulpia myuros* var. *myuros*). Forbs commonly observed in annual grasslands in the study area are yellow star-thistle (*Centaurea solstitialis*), prickly lettuce (*Lactuca serriola*), bristly ox-tongue (*Picris*

echioides), and sweet fennel (*Foeniculum vulgare*). Other forbs observed are perennial peppergrass (*Lepidium latifolium*), Italian thistle (*Carduus pycnocephalus*), horseweed (*Conyza canadensis*), black mustard (*Brassica nigra*), and fireweed (*Epilobium brachycarpum*). The annual grasslands in the study area contain a relatively large proportion of ruderal species, likely because of substantial disturbance from human activities.

Emergent Wetlands

There are approximately 86 acres of emergent wetlands within the study area. The largest areas of emergent wetlands (hereafter referred to as "marshes") occur in the vicinity of the Turning Basin along the Port North and Port South Levees (Figures 3.8-1 and 3.8-2). Marshes were also observed in the study area near the South Cross, Yolo Bypass, and DWSC West Levees. Smaller patches of freshwater marsh that are not shown at the mapping scale used by the Yolo Natural Heritage Program also have the potential to occur along the remaining levees (Yolo Natural Heritage Program 2009). Representative species observed in marshes in the study area were tules (*Scirpus* sp.), cattails (*Typha* sp.), and rushes (*Juncus* sp.). Marshes in the study area represent potentially jurisdictional waters of the United States (including wetlands) that may be subject to regulation by USACE under CWA Section 404. Marsh habitat (i.e., coastal and valley freshwater marsh) is also recognized as a sensitive natural community by the CNDDB (2009).

Seasonal Wetlands

Four small seasonal wetlands occur in the study area at the eastern end of the Port South Levee (Figures 3.8-1 and 3.8-2), totaling approximately 0.3 acre. These wetlands appear to be inundated during wetter times of the year and ongoing and past disturbance contributed to the formation of three of the four seasonal wetlands that appear to have originated from tire tracks within the network of dirt trails in the basin south of South River Road. Representative plant species observed in the seasonal wetlands were hyssop loosestrife (*Lythrum hyssopifolium*), Mediterranean barley (*Hordeum marinum* ssp. *gussoneanum*), Italian ryegrass (*Lolium multiflorum*), and fiddle dock (*Rumex crispus*).

Woodlands and Forest

Small patches of woodland occur in the study area along the Sacramento River North and Sacramento River South Levees, and at the junction of the Sacramento River South and South Cross Levees (Figure 3.8-1). Woodland and forest encompass approximately 16 acres. These patches of woodland are distinguished from the valley foothill riparian habitat by a predominance of valley oaks. The woodlands in the study area have a relatively open canopy. The woodlands in the study area contain trees that have the potential to be considered heritage or landmark trees under the City's Tree Preservation Ordinance.

Open Water

There are approximately 413 acres of open water within the study area. The largest areas are the Sacramento River, DWSC, Turning Basin, and Toe Drain (Figures 3.8-1 and 3.8-2). These areas are TNWs that would be considered jurisdictional by USACE under CWA Section 404. Smaller areas of open water occur in the study area near the Sacramento River North, DWSC East, Yolo Bypass, Port North, and Port South Levees. These smaller areas may or may not fall under USACE jurisdiction under CWA Section 404. Open water areas are essentially unvegetated.

Other Land Cover Types

The following land cover types are associated with human activities.

Pasture

Approximately 28 acres of pasture occur in small patches within the study area near the Sacramento River South and Port North Levees and provide grazing areas for cattle and horses (Figure 3.8-1). Species commonly found in pastures in the region are dallisgrass (*Paspalum dilatatum*), soft chess, and annual bluegrass (*Poa annua*).

Grain and Hay Fields

Small fields used to produce grain and hay are located in the study area near the Sacramento River South Levee and encompass approximately 68 acres (Figure 3.8-1). Although the specific crops were not discernible during the site visits, they were likely barley, oats, or alfalfa, which are commonly grown in the region.

Deciduous Orchards

Deciduous orchards in the study area are confined to a small area near the Sacramento River South Levee that encompasses approximately 6 acres (Figure 3.8-1). At the time of the site visits, the area appeared to be unmaintained (i.e., inactive). Although the specific type of orchard crop could not be discerned, it was likely one of the orchard types commonly known from the region: almonds, walnuts, pears, peaches, or plums.

Irrigated Grain Crops

Approximately 20 acres of irrigated grain crops occur within the study area. These areas are associated with the DWSC West Levee reach and appear to consist entirely of rice fields (Figures 3.8-1 and 3.8-2).

Irrigated Hay Fields

Two small irrigated hay fields occur in the study area near the South Cross Levee and in the southern portion of the Sacramento River South Levee (Figure 3.8-1). Irrigated hay fields encompass approximately 5 acres in study area. These fields are bounded on at least one side by an agricultural toe drain, which presumably carries water for irrigation of the fields. Although the specific crops were not discernible at the time of the site visits, the fields were likely barley, oats, or alfalfa, which are commonly grown in the region.

Irrigated Row and Field Crops

Irrigated row and field crops occur in the study area along the Yolo Bypass, Sacramento River South, and South Cross Levees and encompass approximately 239 acres (Figure 3.8-1). Most of the irrigated row and field crops along the Yolo Bypass Levee appear to be rice fields. At the time of the site visits, the specific crops grown in the remainder of the irrigated row and field crop areas could not be discerned, but they were most likely crops common to the region, such as tomatoes, safflower, sunflowers, melons, or strawberries.

Unvegetated, Vacant, or Developed Areas

Most of the approximately 724 acres that comprise the unvegetated, vacant, and developed areas in the study area occur north of the DWSC along the Sacramento River North, Yolo Bypass, Sacramento Bypass, and Port North Levees (Figure 3.8-1). Vacant areas within the study area commonly contain ruderal species that have the ability to colonize disturbed areas: bristly ox-tongue, yellow star-thistle, common mallow (*Malva neglecta*), milk-thistle (*Silybum marianum*), prickly lettuce, chicory (*Cichorium intybus*), and perennial peppergrass**.** Vegetation in developed portions of the study area consists of ornamental species used for landscaping: English ivy (*Hedera helix*), crapemyrtle (*Lagerstroemia indica*), liquid amber (*Liquidamber styraciflua*), edible fig (*Ficus carica*), and privet (*Ligustrum* sp.).

3.8.2.2.6 Special-Status Plant Species

Special-status plant species are plants that are legally protected under CESA, ESA, or other regulations, as well as species considered sufficiently rare by the scientific community to qualify for such listing. For the purposes of this program analysis, special-status plant species fall into the following categories:

- species listed or proposed for listing as threatened or endangered under ESA (50 CFR 17.12 [listed plants]; various notices in the *Federal Register* [FR] [proposed species]);
- species that are candidates for possible future listing as threatened or endangered under ESA (73 FR 75178, December 10, 2008);
- species listed or proposed for listing by the State of California as threatened or endangered under CESA (14 CCR 670.5);
- species that meet the definitions of rare or endangered under CEQA (State CEQA Guidelines Section 15380);
- plants listed as rare under CNPPA (Fish and Game Code 1900 *et seq.);*
- plants considered by CNPS to be "rare, threatened, or endangered in California" (California Native Plant Society 2009a: Lists 1B and 2); and
- plants listed by CNPS as plants about which more information is needed to determine their status, and plants of limited distribution (California Native Plant Society 2009a: Lists 3 and 4), which may be included as special-status species based on local significance or recent biological information.

A total of 34 special-status plant species were identified as occurring in the vicinity of the study area (California Natural Diversity Database 2009; California Native Plant Society 2009a; U.S. Fish and Wildlife Service 2009). The status, distribution, habitat requirements, and identification period of the 34 species are shown in Table 3.8-3. Two of the 34 species—adobe-lily (*Fritillaria pluriflora*) and little mousetail (*Myosurus minimus* ssp. *apus*)—occur at elevations outside the elevation range of the study area. Of the remaining 32 species, seven are federally or state-listed as endangered or threatened: Suisun thistle (*Cirsium hydrophilum* var. *hydrophilum*), soft bird's-beak (*Cordylanthus mollis* ssp. *mollis*), palmate-bracted bird's-beak (*Cordylanthus palmatus*), Boggs Lake hedge hyssop (*Gratiola heterosepala*), Contra Costa goldfields (*Lasthenia conjugens*), Colusa grass (*Neostapfia colusana*), and Crampton's tuctoria (*Tuctoria mucronata*). The other 25 special-status plant species are listed only on CNPS lists. Riparian habitat, grasslands, and marshes are natural communities observed in the study area that represent potential habitat for special-status plants. Vernal pool

habitat was not observed during the reconnaissance-level field surveys, but some portions of the study area were not accessible at the time of the surveys. The closest special-status plant occurrence to the study area is rose-mallow (*Hibiscus lasiocarpos*) that was documented less than 1 mile away from the Sacramento River North Levee (California Natural Diversity Database 2009).

Table 3.8-3. Special-Status Plants Identified as Occurring in the Vicinity of the Study Area

Common and Scientific Name	Legal Status[a] Federal/ State/CNPS	Geographic Distribution/Floristic Province[1]	Habitat Requirements	Blooming Period	Potential for Occurrence in Study Area
Ferris's milk vetch *Astragalus tener* var. *ferrisiae*	–/–/1B.1	Historic range included the Central Valley from Butte to Alameda Counties; currently only occurs in Butte and Glenn Counties	Seasonally wet areas in meadows and seeps, sub-alkaline flats in valley and foothill grassland; 16–246 feet	Apr–May	Potential habitat present in grasslands but suitable microhabitat (i.e. alkaline soils) may not be present.
Alkali milk vetch *Astragalus tener* var. *tener*	–/–/1B.2	Southern Sacramento Valley, northern San Joaquin Valley, eastern San Francisco Bay	Playas, on adobe clay in valley and foothill grassland, vernal pools on alkali soils; below 197 feet	Mar–Jun	Potential habitat present in grasslands but suitable microhabitat (i.e. adobe clay) may not be present.
Heartscale *Atriplex cordulata*	–/–/1B.2	Western Central Valley and valleys of adjacent foothills	Saline or alkaline soils in chenopod scrub, meadows and seeps, sandy areas in valley and foothill grassland; below 1,230 feet	Apr–Oct	Potential habitat present in grasslands but suitable microhabitat (i.e., soil type) may not be present.
Brittlescale *Atriplex depressa*	–/–/1B.2	Western and eastern Central Valley and adjacent foothills on west side of Central Valley	Alkaline or clay soils in chenopod scrub, meadows and seeps, playas, valley and foothill grassland, vernal pools; below 1,050 feet	Apr–Oct	Potential habitat present in grasslands but suitable microhabitat (i.e. alkaline soils) may not be present.
San Joaquin saltscale *Atriplex joaquiniana*	–/–/1B.2	Western edge of the Central Valley from Glenn to Tulare Counties	Alkaline soils in chenopod scrub, meadows and seeps, playas, valley and foothill grassland; below 2,739 feet	Apr–Oct	Potential habitat present in grasslands but suitable microhabitat (i.e. alkaline soils) may not be present.
Vernal pool smallscale *Atriplex persistens*	–/–/1B.2	Central Valley from Glenn to Tulare Counties	Alkaline vernal pools; 33–377 feet	Jun–Oct	Habitat potentially present in study area.
Bristly sedge *Carex comosa*	–/–/2.1	Inner North Coast Ranges, High Cascade Range, Central Valley, northern Central Coast, San Francisco Bay, San Bernardino mountains, Modoc Plateau	Coastal prairie, marshes and swamps (lake margins), valley and foothill grassland; below 2,050 feet	May–Sep	Potential habitat present in marshes and grassland in study area.

[1] Floristic provinces as defined in Hickman 1993.

Common and Scientific Name	Legal Status[a] Federal/ State/CNPS	Geographic Distribution/Floristic Province[1]	Habitat Requirements	Blooming Period	Potential for Occurrence in Study Area
Pappose tarplant *Centromadia parryi* ssp. *parryi*	–/–/1B.2	Southern North Coast Ranges, southern Sacramento Valley, northern and central Western California	Coastal prairie, meadows and seeps, coastal salt marshes and swamps, vernally mesic valley and foothill grassland; below 1,378 feet	May–Nov	Potential habitat present in marshes and grassland but suitable microhabitat (i.e., salt marsh, vernally mesic grassland) may not be present.
Bolander's water-hemlock *Cicuta maculata* var. *bolanderi*	–/–/2.1	Southern Sacramento Valley, Central Coast, South Coast	Coastal, freshwater, or brackish marshes and swamps; below 656 feet	Jul–Sep	Potential habitat present in marshes in study area.
Suisun thistle *Cirsium hydrophilum* var. *hydrophilum*	E/–/1B.1	Known from only two extant occurrences on Grizzly Island in Solano County	Salt marshes and swamps; below 3 feet	Jun–Sep	Potential habitat present in marshes but suitable microhabitat requirements (i.e., high alkalinity) may not be met.
Soft bird's-beak *Cordylanthus mollis* ssp. *mollis*	E/R/1B.2	Northern Central Coast with occurrences in Contra Costa, Marin*, Napa, Sacramento*, Solano, and Sonoma* Counties	Coastal salt marshes and swamps; below 10 feet	Jul–Nov	Potential habitat present in marshes but suitable microhabitat requirements (i.e., high alkalinity) may not be met.
Palmate-bracted bird's-beak *Cordylanthus palmatus*	E/E/1B.1	Livermore Valley and scattered locations in the Central Valley from Colusa to Fresno Counties	Alkaline grassland, alkali meadow, chenopod scrub; 16–508 meters	May–Oct	Potential habitat present in grasslands but suitable microhabitat (i.e. alkaline soils) may not be present.
Dwarf downingia *Downingia pusilla*	–/–/2.2	Inner North Coast Ranges, southern Sacramento Valley, northern and central San Joaquin Valley	Mesic areas in valley and foothill grassland, vernal pools; below 1,460 feet	Mar–May	Potential habitat present in grasslands but suitable microhabitat (i.e., mesic areas) may not be present.
Stinkbells *Fritillaria agrestis*	–/–/4.2	Outer North Coast Ranges, Sierra Nevada foothills, Central Valley, Central Western California	Clay, sometimes serpentine soils in chaparral, cismontane woodland, pinyon-juniper woodland, valley and foothill grassland; 33–5,102 feet	Mar–Jun	Potential habitat present in grasslands but suitable microhabitat (i.e., clay, serpentine soils) may not be present.
Fragrant fritillary *Fritillaria liliacea*	–/–/1B.2	Central Western California with occurrences in Alameda, Contra Costa, Monterey, Marin, San Benito, Santa Clara, San Francisco, San Mateo, Solano, and Sonoma Counties	Coastal prairie, coastal scrub, valley and foothill grassland, cismontane woodland, often on serpentine; 10–1,345 feet	Feb–Apr	Potential habitat present in grasslands, but suitable microhabitat (i.e., serpentine) may not be present.

Common and Scientific Name	Legal Status[a] Federal/ State/CNPS	Geographic Distribution/Floristic Province[1]	Habitat Requirements	Blooming Period	Potential for Occurrence in Study Area
Adobe-lily *Fritillaria pluriflora*	–/–/1B.2	Northern Sierra Nevada foothills, Inner North Coast Ranges, edges of Sacramento Valley	Often adobe soils in chaparral, cismontane woodland, valley and foothill grassland; 197–2,313 feet	Feb–Apr	Species occurs outside elevation of the study area.
Boggs Lake hedge hyssop *Gratiola heterosepala*	–/E/1B.2	Inner North Coast Ranges, central Sierra Nevada foothills, Sacramento Valley, Modoc Plateau	Marshes and swamps along lake margins, vernal pools on clay soils; 32–7,792 feet	Apr–Aug	Potential habitat present in marshes. Vernal pool habitat potentially present.
Rose-mallow *Hibiscus lasiocarpos*	–/–/2.2	Central and southern Sacramento Valley, deltaic Central Valley, and elsewhere in the U.S.	Freshwater marsh along rivers and sloughs; below 394 feet	Jun–Sep	Potential habitat present in marshes and nearest occurrence is ~1 mile from the Sacramento River North Levee.
Carquinez goldenbush *Isocoma arguta*	–/–/1B.1	Deltaic Sacramento Valley in the Suisun Slough	Alkaline valley and foothill grassland; 3–66 feet	Aug–Dec	Potential habitat present in grasslands but suitable microhabitat (i.e. alkaline soils) may not be present.
Northern California black walnut *Juglans hindsii*	–/–/1B.1	Last two native stands in Napa and Contra Costa Counties; historically widespread through southern Inner North Coast Ranges, southern Sacramento Valley, northern San Joaquin Valley, San Francisco Bay	Riparian scrub and riparian woodland; below 1,443 feet	Apr–May	Potential habitat present; no native stands observed during reconnaissance-level field surveys in 2007.
Contra Costa goldfields *Lasthenia conjugens*	E/–/1B.1	North Coast, southern Sacramento Valley, San Francisco Bay, South Coast	Mesic areas in cismontane woodland, alkaline playas, valley and foothill grassland, vernal pools; below 1,542 feet	Mar–Jun	Potential habitat present in grasslands. Vernal pool habitat potentially present.
Delta tule pea *Lathyrus jepsonii* var. *jepsonii*	–/–/1B.2	Central Valley, San Francisco Bay	Freshwater and brackish marshes and swamps; below 13 feet	May–Jul (uncommonly Sep)	Potential habitat present in marshes.
Legenere *Legenere limosa*	–/–/1B.1	Sacramento Valley, North Coast Ranges, northern San Joaquin Valley and Santa Cruz mountains	Vernal pools; below 2,887 feet	Apr–Jun	Habitat potentially present in study area.
Heckard's pepper-grass *Lepidium latipes* var. *heckardii*	–/–/1B.2	Southern Sacramento Valley	Alkaline flats in valley and foothill grassland; 32–656 feet	Mar–May	Potential habitat present in grasslands but suitable microhabitat (i.e., alkaline soils) may not be present.

Common and Scientific Name	Legal Status[a] Federal/ State/CNPS	Geographic Distribution/Floristic Province[1]	Habitat Requirements	Blooming Period	Potential for Occurrence in Study Area
Mason's lilaeopsis *Lilaeopsis masonii*	–/R/1B.1	Southern Sacramento Valley, northeastern San Francisco Bay	Riparian scrub, brackish or freshwater marshes and swamps; below 33 feet	Apr–Nov	Potential habitat present in riparian habitat and marshes.
Delta mudwort *Limosella subulata*	–/–/2.1	Deltaic Central Valley with occurrences in Contra Costa, Sacramento, San Joaquin, and Solano Counties; Oregon	Marshes and swamps; below 10 feet	May–Aug	Potential habitat present in marshes.
Little mousetail *Myosurus minimus* ssp. *apus*	–/–/3.1	Central Valley, San Francisco Bay area, southern Outer Coast Ranges, South Coast	Alkaline soils in valley and foothill grassland and vernal pools; 66–2,100 feet	Mar–Jun	Potential habitat present in grasslands but suitable microhabitat (i.e. alkaline soils) may not be present. Vernal pool habitat potentially present.
Baker's navarretia *Navarretia leucocephala* ssp. *bakeri*	–/–/1B.1	Inner North Coast Ranges, western Sacramento Valley	Mesic areas in cismontane woodland, lower montane coniferous forest, meadows and seeps, valley and foothill grassland, vernal pools;16–5,709 feet	Apr–Jul	Moderate; potential habitat present in grasslands but suitable microhabitat (i.e., mesic areas) may not be present
Colusa grass *Neostapfia colusana*	T/E/1B.1	Central Valley with scattered occurrences from Colusa to Merced Counties	Adobe soils of vernal pools; 16–656 feet	May–Aug	Habitat potentially present in study area.
Bearded popcorn-flower *Plagiobothrys hystriculus*	–/–/1B.1	Presumed extinct until recent rediscovery in the Montezuma Hills	Often vernal swales in mesic valley and foothill grassland, vernal pool margins; below 171 feet	Apr–May	Potential habitat present in grasslands, but suitable microhabitat (i.e., vernal swales) may not be present. Vernal pool habitat potentially present.
Sanford's arrowhead *Sagittaria sanfordii*	–/–/1B.2	Scattered locations in Central Valley and Coast Ranges from Del North to Fresno Counties	Freshwater marshes, sloughs, canals, and other slow-moving water habitats; below 2,132 feet	May–Oct	Moderate; potential habitat present in marshes in the study area.
Side-flowering skullcap *Scutellaria lateriflora*	–/–/2.2	Northern San Joaquin Valley, east of Sierra Nevada; New Mexico, Oregon	Mesic meadows and seeps, marshes and swamps; below 1,640 feet	Jul–Sep	Potential habitat present in marshes.

Common and Scientific Name	Legal Status[a] Federal/ State/CNPS	Geographic Distribution/Floristic Province[1]	Habitat Requirements	Blooming Period	Potential for Occurrence in Study Area
Suisun Marsh aster *Symphyotrichum lentum* (formerly *Aster lentus*)	–/–/1B.2	Sacramento Valley, Central Coast, San Francisco Bay	Brackish and freshwater marshes and swamps; below 10 feet	May–Nov	Potential habitat present in marshes.
Crampton's tuctoria *Tuctoria mucronata*	E/E/1B.1	Southwestern Sacramento Valley, Solano and Yolo Counties	Mesic areas in valley and foothill grassland, vernal pools; 16–33 feet	Apr–Aug	Potential habitat present in grasslands but suitable microhabitat (i.e., mesic areas) may not be present. Vernal pool habitat potentially present.

[a] Status explanations:

Federal

E = listed as endangered under the Federal Endangered Species Act.
T = listed as threatened under the Federal Endangered Species Act.
– = no listing.

State

E = listed as endangered under the California Endangered Species Act.
R = listed as rare under the California Native Plant Protection Act (this category is no longer used for newly listed plants, but some plants previously listed as rare retain this designation.
– = no listing.

California Native Plant Society (CNPS)

1B = List 1B species: rare, threatened, or endangered in California and elsewhere.
2 = List 2 species: rare, threatened, or endangered in California but more common elsewhere.
3 = List 3 species: more information is needed about this plant
4 = List 4 species: limited distribution and on a watch list.
0.1 = seriously endangered in California.
0.2 = fairly endangered in California.
* = presumed extirpated from that County.

1

3.8.2.2.7 Invasive Plant Species

Plant species that are considered invasive by the California Department of Food and Agriculture and California Invasive Plant Council are well represented and fairly widespread within the study area, particularly in grassland and vacant areas (California Invasive Plant Council 2006, 2007; California Department of Food and Agriculture 2009). The California Department of Food and Agriculture and California Invasive Plant Council ratings for the invasive species observed during the site visits are provided in the plant list for the study area (Appendix F).

3.8.2.2.8 Protected Tree Resources

The study area contains numerous trees (e.g., valley oaks, interior live oaks [*Q. wislizeni*]) that may be considered heritage or landmark trees under the City's Tree Preservation Ordinance.

3.8.3 Environmental Consequences

This section describes the vegetation and wetlands effects associated with the proposed program. It describes the methods used to determine the effects of the program and lists the thresholds used to conclude whether an effect would be significant. How this effect differs among reaches is discussed, if applicable. Measures to mitigate (i.e., avoid, minimize, rectify, reduce, eliminate, or compensate for) significant effects accompany each effect discussion.

3.8.3.1 Assessment Methods

Evaluation of the vegetation and wetland effects in this section is based on the information provided by technical maps, reports, and other documents that describe the resource conditions of the study area. This information was then compared to the type and location of proposed flood and recreation alternatives to determine whether effects would occur.

3.8.3.2 Determination of Effects

For this analysis, based on professional practice and State CEQA Guidelines Appendix G (14 CCR 15000 *et seq*.), an effect pertaining to vegetation and wetlands was considered an adverse effect under NEPA and a significant impact under CEQA if it would:

- have a substantial adverse effect, either directly or through habitat modification, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations or by DFG or USFWS;
- have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, or regulations, or by DFG or USFWS;
- have a substantial adverse effect on federally protected wetlands as defined by CWA Section 404 (including, but not limited to, marshes and vernal pools) through direct removal, filling, hydrological interruption, or other means;
- conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance; or

- conflict with the provisions of an adopted habitat conservation plan, natural communities conservation plan, or other approved local, regional, or state habitat conservation plan.

3.8.3.2.1 Effect Assumptions

The following assumptions were made regarding program effects on vegetation and wetlands in the study area.

- All program construction activities, including equipment staging and access, would take place only within the study area.
- Project-level analyses would be conducted to assess the effects of future individual projects along the nine levee reaches.
- The program would comply with USACE's policy on vegetation and levees (i.e., no vegetation is permitted within the levee's operation and maintenance zone, which includes the levee itself and an area extending 15 feet from the landside and waterside toes). These areas would be maintained free of woody vegetation in perpetuity.
- Fill or borrow material would be obtained from a quarry or other authorized location.
- There would be effects related to the routine operation or maintenance activities under the proposed program. WSAFCA would continue current levee maintenance actions (as described in Chapter 2, Alternatives). Maintenance of the relief wells and lateral drainage system would be performed from maintenance roads.
- Discharge of fill into waters of the United States associated with the proposed program would require a Rivers and Harbors Act Section 10 permit, a CWA Section 404 permit from the USACE Sacramento District, and CWA Section 401 certification from the Central Valley RWQCB. Before construction begins, WSAFCA would obtain all necessary permits pertaining to affected waters of the United States. The permitting process would also require compensation for construction-, operation-, and maintenance-related effects.
- Grading would require a CWA Section 402 permit and preparation of a SWPPP.
- Grading or other construction activities within the bed, bank, or channel of a stream would require a streambed alteration agreement from DFG.

3.8.3.2.2 Effect Mechanisms

Vegetation and wetland resources could be directly and indirectly affected by the proposed program. The following types of activities could cause varying degrees of effects on these resources:

- grading, and fill placement during construction of levee alternatives;
- channel dewatering or installation of temporary water-diversion structures;
- temporary stockpiling and sidecasting of soil, construction materials, or other construction wastes;
- soil compaction, dust, and water runoff from the construction site into adjacent areas;
- introduction or spread of invasive plant species into adjacent open space areas; and

- runoff of herbicides, fertilizers, diesel fuel, gasoline, oil, raw concrete, or other toxic materials used for levee alternatives, operations, and maintenance into sensitive biological resource areas (e.g., riparian habitat, wetlands).

3.8.3.3 Effects and Mitigation Measures

3.8.3.3.1 No Action Alternative

To recap from Chapter 2, Alternatives, the No Action Alternative is the continuation of the existing deficiencies along the nine levee reaches and absence of levee alternatives to increase the level of protection. Current levee operations and maintenance activities would continue. No construction-related effects on vegetation or waters of United States would occur.

Without levee improvements, there is the continued risk of levee failure. Under these conditions, any of the levee deficiencies could cause portions of the levee system to fail, triggering widespread flooding and extensive damage. As noted in the description of the No Action Alternative, a catastrophic levee failure would result in flooding and inundation up to 15 feet in certain areas. Flooding of this magnitude could significantly affect vegetation by uprooting plants, subjecting vegetation to extended inundation and stress, eroding the soil, and otherwise damaging the vegetation by hydraulic force. The potential construction footprint area alone (which includes a 500-foot-wide levee corridor) contains 236.5 acres of valley foothill riparian (a sensitive natural community) and 16.4 acres of woodlands and forest, among other land cover types. Loss or damage to these land cover types would result in significant short- and long-term effects on habitat quality and the wildlife that use these habitats. Some vegetation is considered special-status or supports habitat for endangered and special-status species (e.g., valley elderberry longhorn beetle). In addition, cleanup and repair activities could result in damage or removal of vegetation (including special-status species) and the disturbance or fill of waters of the United States. All of these effects would be considered significant; however, given the uncertainty of the occurrence or magnitude of such an event, potential effects on vegetation and waters of the United States cannot be fully quantified based on available information.

In its levee vegetation guidance, USACE has established a woody vegetation-free zone required for operations and maintenance of Federal project levees. Woody vegetation has been allowed to persist within the study area and more broadly throughout the SRFCP area in part to provide the functions and values attributed to riparian vegetation. However, in light of recent levee failures and flooding disasters in the United States (e.g., the flooding related to Hurricanes Katrina and Rita), compliance with the vegetation-free zone will be more strictly adhered to and enforced.

Compliance with the levee vegetation guidance could result in the removal of a substantial amount of vegetation, including vegetation that comprises riparian habitat and supports fish and wildlife populations (including special-status species). But for areas where a setback levee is proposed, which may allow existing vegetation to be preserved, or where the vegetation is found to be in compliance with USACE levee vegetation guidance, the No Action Alternative and flood and recreation program alternatives could result in effects on vegetation and wetlands that are comparatively similar. However, absent a site-specific study of the application of the USACE levee vegetation guidance, calculation of the magnitude and significance of effects are too speculative based on available information.

3.8.3.3.2 Flood and Recreation Program Alternatives

Effect VEG-1: Permanent Loss of Woody Riparian Vegetation from Levee Vegetation Removal

All levee alternatives proposed under the WSLIP will follow USACE's policies regarding vegetation on levees, which forbid all woody vegetation on the crown, slopes, and within 15 feet of the waterside and landside levee toes. These zones will be maintained free of woody vegetation in perpetuity. Thus, the removal of a substantial amount of mature trees and vegetation from the banks of the Sacramento River may be required. The woody riparian community in the study area (i.e., valley foothill riparian habitat) is considered a sensitive natural community.

Permanent loss of the woody vegetation in compliance with USACE's policies would result in a significant effect on riparian habitat. The full extent of this effect is dependent on what portion of the existing levee would be officially deemed as the levee prism according to USACE. In some cases, the current levees are wider than the minimum requirements (or may become wider with the implementation of program alternatives such as an adjacent levee raise) and existing vegetation may fall outside of the vegetation-free zone. Moreover, dependent on site conditions, variances may be issued on a case-by-case basis that would allow vegetation to remain. Therefore, these effects are considered significant to significant and avoidable. Implementation of Mitigation Measure VEG-MM-1 would reduce but may not fully compensate for effects.

Program Alternatives Associated with This Effect

Implementation of all flood and recreation program alternatives could cause this effect:

Program	Alternative	
Flood	▪ Flood wall	▪ Seepage berm
	▪ Levee raise (in place)	▪ Sheet pile wall
	▪ Levee raise (adjacent)	▪ Slurry cutoff wall
	▪ Levee raise (full)	▪ Slope flattening
	▪ Closure structure	▪ Stability berm
	▪ Interior drain	▪ Rock slope protection
	▪ Jet grouting	▪ Setback levee
	▪ Relief wells	▪ Vegetation removal
Recreation	▪ Trails	▪ Developed water access
	▪ Riverside parks	▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect would occur in all nine program reaches. The degree of this effect would be greater in the Sacramento River North and South Levee reaches, Port North and South Levee reaches, and the South Cross Levee because these reaches support the greatest amount of riparian habitat and associated wildlife species in comparison to the other reaches in the study area.

Effect VEG-1 Finding	With Mitigation
Significant	Potentially significant and unavoidable

Mitigation

Mitigation Measure VEG-MM-1: Compensate for the Loss of Woody Riparian Habitat

For direct effects on woody riparian habitat that cannot be avoided, WSAFCA will compensate for the loss of riparian habitat to ensure no net loss of habitat functions and values. Compensation ratios will be based on site-specific information and determined through coordination with the appropriate state and Federal agencies during the permitting process. Compensation will be provided based on the ratio determined (e.g., 2:1= 2 acres restored/created/enhanced or credits purchased for every 1 acre removed) and may be a combination of off-site restoration or mitigation credits. WSAFCA will develop a restoration and monitoring plan that describes how riparian habitat will be enhanced or recreated and monitored over a minimum period of time, as determined by the appropriate state and Federal agencies.

If WSAFCA identifies on-site areas (adjacent to the levees) that are outside the USACE vegetation-free zone and chooses to compensate on site or in the project vicinity, a revegetation plan will be prepared. The revegetation plan will be developed prior to the removal of existing riparian vegetation and will be conducted on site or in the project vicinity to the extent feasible; however, mitigation site selection will avoid areas where future levee alternatives or maintenance is likely.

The revegetation plan will be prepared by a qualified restoration ecologist and reviewed by the appropriate agencies. The revegetation plan will specify the planting stock appropriate for each riparian land cover type and each mitigation site, ensuring the use of genetic stock from the project area. The plan will employ the most successful techniques available at the time of planting. Success criteria will be established as part of the plan. Plantings will be maintained for a minimum of 5 years, including weed removal, irrigation, and herbivory protection.

WSAFCA will monitor the plantings annually for 4 years, followed by monitoring every 2 years for the next 6 years to ensure that the plantings have established successfully. WSAFCA will submit annual monitoring reports of survival to the regulatory agencies issuing permits related to habitat effects, including DFG, USACE, NMFS, and USFWS. Replanting will be necessary if success criteria are not met. The riparian habitat mitigation will be considered successful when the sapling trees established meet the success criteria, the habitat no longer requires active management, and vegetation is arranged in groups that, when mature, replicate the area, natural structure, and species composition of similar riparian habitats in the region.

Effect VEG-2: Potential Loss of Special-Status Plant Populations Caused by Habitat Loss Resulting from Program Construction

Construction activities associated with the program would result in ground disturbance that would remove one or more habitats that could potentially contain special-status plant populations. Program construction activities could result in the direct loss or indirect disturbance of special-status plants that are known to grow or that could occur in the program area (see Table 3.8-3 for a list of these species). Effects on special-status plants could result in a substantial reduction in local population size, lowered reproductive success, or habitat fragmentation. Because WSAFCA cannot guarantee that special-status plants would be avoided during future activities, this levee deficiency treatment could result in a significant impact on special-status plants. Depending on the plant (listed versus unlisted) and the extent of impact on the population, implementation of mitigation measures VEG-MM-2, and if applicable, mitigation measures VEG-MM-3, VEG-MM-4, VEG-MM-5, and VEG-MM-6 may avoid or reduce this future effect to a less-than-significant level. The final significance

determination will need to be made on a project-by-project basis for future phases of the proposed program after field surveys have been conducted (mitigation measure VEG-MM-2) and through consultation with the appropriate resource agency (USFWS and/or DFG). Because the effectiveness of measures to reduce these effects to lesser levels is not known at this time, this effect is considered significant and potentially unavoidable.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall ▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Closure structure ▪ Interior drain ▪ Jet grouting ▪ Relief wells	▪ Seepage berm ▪ Sheet pile wall ▪ Slurry cutoff wall ▪ Slope flattening ▪ Stability berm ▪ Rock slope protection ▪ Setback levee ▪ Vegetation removal
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect would occur in all nine program reaches.

Effect VEG-2 Finding	With Mitigation
Significant	Less than significant to potentially significant and unavoidable

Mitigation

Mitigation Measure VEG-MM-2: Retain Qualified Botanists to Conduct Floristic Surveys for Special-Status Plants during Appropriate Identification Periods

WSAFCA will retain qualified botanists to survey the study area to document the presence of special-status plants before project implementation. The botanists will conduct a floristic survey that follows the DFG botanical survey guidelines (California Department of Fish and Game 2000). All plant species observed will be identified to the level necessary to determine whether they qualify as special-status plants or are plant species with unusual or significant range extensions. The guidelines also require that field surveys be conducted when special-status plants that could occur in the area are evident and identifiable, generally during the blooming period. To account for different special-status plant identification periods, one or more series of field surveys may be required in spring and summer.

Special-status plant populations identified during the field surveys will be mapped and documented as part of the public record.

Mitigation Measure VEG-MM-3: Redesign Proposed Projects to Avoid Substantial Effects on Special-Status Plants

If one or more special-status plants are identified in the study area during preconstruction surveys, WSAFCA will redesign or modify proposed project components of the program to avoid indirect or direct effects on special-status plants.

If complete avoidance of special-status plants is not feasible, the effects of the proposed program on special-status plants would be significant and unavoidable.

If special-status plants can be avoided by redesigning proposed projects, implementation of Mitigation Measures VEG-MM-4, VEG-MM-5, and VEG-MM-6 would avoid significant effects on special-status plants. Avoidance, minimization, and compensation measures for riparian habitat, wetlands, and protected trees are discussed separately below under their respective effects (Effects VEG-3, VEG-4, and VEG-5).

Mitigation Measure VEG-MM-4: Conduct Mandatory Contractor/Worker Awareness Training for Construction Personnel

Before any work occurs in the study area, including grading, a qualified biologist will conduct mandatory contractor/worker awareness training for construction personnel. The awareness training will be provided to all construction personnel to brief them on the need to avoid effects on sensitive biological resources (e.g., riparian habitat, special-status species, special-status wildlife habitat) and the penalties for not complying with permit requirements. The biologist will inform all construction personnel about the life history of special-status species with potential for occurrence on site, the importance of maintaining habitat, and the terms and conditions of the biological opinion or other authorizing document. Proof of this instruction will be submitted to USFWS, DFG, or other overseeing agency, as appropriate.

The training will also cover the restrictions and guidelines that must be followed by all construction personnel to reduce or avoid effects on special-status species during project construction. The crew foreman will be responsible for ensuring that crew members adhere to the guidelines and restrictions. Educational training will be conducted for new personnel as they are brought on the job during the construction period. General restrictions and guidelines for vegetation and wildlife that must be followed by construction personnel are listed below.

- Project-related vehicles will observe the posted speed limit on hard-surfaced roads and a 10-mile-per-hour speed limit on unpaved roads during travel in the project site.
- Project-related vehicles and construction equipment will restrict off-road travel to the designated construction area.
- All food-related trash will be disposed of in closed containers and removed from the study area at least once a week during the construction period. Construction personnel will not feed or otherwise attract fish or wildlife to the project site.
- No pets or firearms will be allowed in the project site.
- To prevent possible resource damage from hazardous materials such as motor oil or gasoline, construction personnel will not service vehicles or construction equipment outside designated staging areas.

For special-status wildlife, any worker who inadvertently injures or kills a special-status wildlife species (discussed in Section 3.10, Wildlife) or finds one dead, injured, or entrapped will immediately report the incident to the biological monitor. The monitor will immediately notify WSAFCA, who will provide verbal notification to the USFWS Endangered Species Office or the local DFG warden or biologist within 3 working days. WSAFCA will follow up with written notification to USFWS or DFG within 5 working days.

Mitigation Measure VEG-MM-5: Install Construction Barrier Fencing to Protect Sensitive Biological Resources Adjacent to the Construction Zone

The construction specifications will require that WSAFCA retain a qualified biologist to identify sensitive biological resources (e.g., special-status species, riparian habitat, wetlands, elderberry shrubs) adjacent to the construction zone that are to be avoided during construction. Sensitive biological resources located adjacent to the directly affected area required for construction, including staging and access, will be fenced off to avoid disturbance in these areas. If necessary, concrete barriers will also be installed to protect sensitive biological resources in areas adjacent to the directly affected area.

Before construction, the contractor will work with the project engineer and a resource specialist to identify the locations for the barrier fencing (and, if necessary, concrete barriers) and will place stakes around the sensitive biological resources to indicate their locations. The protected area will be clearly identified on the construction specifications. The fencing will be installed at least 20 feet from each sensitive biological resource and will be in place before construction activities are initiated. The fencing will be maintained by WSAFCA or its contractor throughout the duration of the construction period. If the fencing is removed, damaged, or otherwise compromised during the construction period, construction activities will cease until the fencing is replaced.

Mitigation Measure VEG-MM-6: Retain a Biological Monitor

The program proponent will retain qualified biologists to monitor construction activities adjacent to sensitive biological resources (e.g., special-status species, riparian habitat, wetlands, elderberry shrubs). The biologists will assist the construction crew, as needed, to comply with all program implementation restrictions and guidelines. In addition, the biologists will be responsible for ensuring that the program proponent or its contractors maintain the construction barrier fencing adjacent to sensitive biological resources.

Effect VEG-3: Disturbance or Removal of Riparian Habitat as a Result of Program Construction

Riparian habitat that occurs outside of the USACE vegetation-free zones would be disturbed or removed during construction activities associated with the proposed program flood and recreation alternatives. The disturbance or removal of riparian vegetation as a result of the proposed program would be considered a significant effect. Implementation of Mitigation Measures VEG-MM-1, VEG-MM-4, VEG-MM-5, VEG-MM-6, and VEG-MM-7 would reduce this effect to a lesser level.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall	▪ Seepage berm
	▪ Levee raise (in place)	▪ Sheet pile wall
	▪ Levee raise (adjacent)	▪ Slurry cutoff wall
	▪ Levee raise (full)	▪ Slope flattening
	▪ Closure structure	▪ Stability berm
	▪ Interior drain	▪ Rock slope protection
	▪ Jet grouting	▪ Setback levee
	▪ Relief wells	▪ Vegetation removal
Recreation	▪ Trails	▪ Developed water access
	▪ Riverside parks	▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect would occur in all nine program reaches. The degree of this effect would be greater in the Sacramento River North and South Levee reaches, Port North and South Levee reaches, and the South Cross Levee because these reaches support the greatest amount of riparian habitat and associated wildlife species in comparison to the other reaches in the study area.

Effect VEG-3 Finding	With Mitigation
Significant	Less than significant

Mitigation

Mitigation Measure VEG-MM-1: Compensate for the Loss of Woody Riparian Habitat

The implementation of Mitigation Measure VEG-MM-1 under Effect Veg-3 may include on-site woody riparian habitat restoration or creation in addition to, or in place of, off-site restoration or mitigation credits.

Mitigation Measure VEG-MM-4: Conduct Mandatory Contractor/Worker Awareness Training for Construction Personnel

Mitigation Measure VEG-MM-5: Install Construction Barrier Fencing to Protect Sensitive Biological Resources Adjacent to the Construction Zone

Mitigation Measure VEG-MM-6: Retain a Biological Monitor

Mitigation Measure VEG-MM-7: Redesign Proposed Projects to Avoid and Minimize Effects on Sensitive Biological Resources

WSAFCA will redesign proposed projects to avoid and minimize effects on sensitive biological resources (e.g., riparian areas outside the USACE woody vegetation-free zones, wetlands, protected trees).

Effect VEG-4: Loss of Wetlands and Waters of the United States as a Result of Program Construction

The study area contains numerous features that are or have the potential to be waters of the United States, including wetlands. These features include, but are not limited to, emergent wetlands (approximately 86 acres), irrigated grain crops (approximately 20 acres), open water (approximately 413 acres), and seasonal wetlands (0.3 acre). Construction activities associated with this treatment would result in the loss of waters of the United States, including wetlands. This effect would be considered a significant effect because the proposed program would have a significant effect on wetlands and other waters that are protected under Federal law through direct removal, filling, hydrological interruption, or other means. Implementation of Mitigation Measures VEG-MM-4, VEG-MM-5, VEG-MM-6, VEG-MM-7, and VEG-MM-8 would reduce this effect to a lesser level.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall	▪ Seepage berm
	▪ Levee raise (in-place)	▪ Sheet pile wall
	▪ Levee raise (adjacent)	▪ Slurry cutoff wall
	▪ Levee raise (full)	▪ Slope flattening
	▪ Closure structure	▪ Stability berm
	▪ Interior drain	▪ Rock slope protection
	▪ Jet grouting	▪ Setback levee
	▪ Relief wells	▪ Vegetation removal
Recreation	▪ Trails	▪ Developed water access
	▪ Riverside parks	▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect would occur in all nine program reaches.

Effect VEG-4 Finding	With Mitigation
Significant	Less than significant

Mitigation

Mitigation Measure VEG-MM-4: Conduct Mandatory Contractor/Worker Awareness Training for Construction Personnel

Mitigation Measure VEG-MM-5: Install Construction Barrier Fencing to Protect Sensitive Biological Resources Adjacent to the Construction Zone

Mitigation Measure VEG-MM-6: Retain a Biological Monitor

Mitigation Measure VEG-MM-7: Redesign Proposed Projects to Avoid and Minimize Effects on Sensitive Biological Resources

Mitigation Measure VEG-MM-8: Compensate for the Loss of Wetlands and Other Waters

Compensation for the loss of wetlands will include restoring or enhancing in-kind wetland habitat at a mitigation ratio that will be developed in coordination with regulatory agencies to ensure no net loss of wetland habitat functions and values. Before the removal of existing emergent wetland vegetation, WSAFCA will prepare a revegetation plan to compensate for the loss of wetland habitat and submit the plan to the appropriate regulatory agencies for review. The revegetation plan will be prepared by a qualified restoration ecologist. The revegetation plan will specify the planting stock appropriate for each wetland land cover type and each mitigation site, ensuring the use of genetic stock from the project area. The plan will employ the most successful techniques available at the time of planting. Success criteria will be established as part of the plan. The revegetation will be conducted on site or in the vicinity to the extent feasible, but mitigation site selection will avoid areas where future levee alternatives or maintenance would be likely. If off-site mitigation is necessary, a location that does not currently support wetlands but is capable of supporting wetland habitats should be selected. An area that currently supports minimal habitat value would be desirable. WSAFCA will implement the revegetation plan, maintain plantings for a minimum of 5 years (including weed removal, irrigation, and herbivory protection), and conduct annual monitoring for 4 years, followed by monitoring every 2 years for the next 6 years. Existing native wetland vegetation from the affected sites should be harvested and maintained for replanting after construction.

Effect VEG-5: Disturbance or Removal of Protected Trees as a Result of Program Construction

The study area contains numerous trees that may be considered heritage or landmark trees under the City's Tree Preservation Ordinance. Construction activities associated with this treatment would result in the loss of protected trees, which would conflict with the local ordinance. This would be a significant impact. Implementation mitigation measures would reduce this effect to a less-than-significant level.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall	▪ Seepage berm
	▪ Levee raise (in place)	▪ Sheet pile wall
	▪ Levee raise (adjacent)	▪ Slurry cutoff wall
	▪ Levee raise (full)	▪ Slope flattening
	▪ Closure structure	▪ Stability berm
	▪ Interior drain	▪ Rock slope protection
	▪ Jet grouting	▪ Setback levee
	▪ Relief wells	▪ Vegetation removal
Recreation	▪ Trails	▪ Developed water access
	▪ Riverside parks	▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect would occur in all nine program reaches. The degree of this effect would be greater in the Sacramento River North and South Levee reaches, Port North and South Levee reaches, and the South Cross Levee because these reaches support the greatest amount of riparian habitat and associated wildlife species in comparison to the other reaches in the study area.

Effect VEG-5 Finding	With Mitigation
Significant	Less than significant

Mitigation

Mitigation Measure VEG-MM-4: Conduct Mandatory Contractor/Worker Awareness Training for Construction Personnel

Mitigation Measure VEG-MM-5: Install Construction Barrier Fencing to Protect Sensitive Biological Resources Adjacent to the Construction Zone

Mitigation Measure VEG-MM-6: Retain a Biological Monitor

Mitigation Measure VEG-MM-7: Redesign Proposed Projects to Avoid and Minimize Effects on Sensitive Biological Resources

Mitigation Measure VEG-MM-9: Conduct a Tree Survey

WSAFCA will retain a certified arborist to conduct a tree survey to identify protected trees in the study area. The arborist will document the results of the tree survey in a report that includes the location, species, size (diameter at breast height), overall health, and dripline diameter of the trees. If the arborist's survey does not identify any protected trees that would be removed or damaged as a result of the proposed program, no additional mitigation would be necessary. If protected trees are present, WSAFCA will implement Mitigation Measure VEG-MM-10.

Mitigation Measure VEG-MM-10: Compensate for Loss of Protected Trees

WSAFCA will apply for a tree permit for the removal of any protected trees during construction. WSAFCA will replace trees that must be removed with trees at or near the location of the effect or another location within West Sacramento approved by the City's tree administrator. WSAFCA will also replace the replacement tree if it dies within 3 years of the initial planting. Replacement is not required if a tree is removed because it poses a risk, hosts a plant parasite, or is otherwise an undesirable species or specimen at the discretion of the City's tree administrator.

Replacement trees are required at a ratio of 1:1 (i.e., 1-inch diameter of replacement plant for every 1-inch diameter of tree removed). Trees may also be mitigated through payment of an in-lieu fee, which will be used to purchase and plant trees elsewhere in West Sacramento. Mitigation will be subject to approval by the City's tree administrator and may consider species affected, replacement species, location, health and vigor, habitat value, and other factors to determine fair compensation for tree loss.

Effect VEG-6: Introduction or Spread of Invasive Plants as a Result of Program Construction

Invasive plants are already present in the study area. However, construction activities associated with this treatment could introduce new invasive plants to the study area or contribute to the spread of existing invasive plants to un-infested areas outside the study area. Invasive plants or their seeds may be dispersed by construction equipment if appropriate prevention measures are not implemented. The introduction or spread of invasive plants as a result of the proposed project could have a significant effect on sensitive natural communities within and outside the study area by displacing native flora. The implementation of one or more of the BMPs described in the environmental commitment to avoid or minimize the spread or introduction of invasive plant species (Section 2.9 of Chapter 2, Alternatives) will ensure that the proposed program would not have a significant effect on sensitive natural communities from the introduction or spread of invasive plants.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall	▪ Seepage berm
	▪ Levee raise (in place)	▪ Sheet pile wall
	▪ Levee raise (adjacent)	▪ Slurry cutoff wall
	▪ Levee raise (full)	▪ Slope flattening
	▪ Closure structure	▪ Stability berm
	▪ Interior drain	▪ Rock slope protection
	▪ Jet grouting	▪ Setback levee
	▪ Relief wells	▪ Vegetation removal
Recreation	▪ Trails	▪ Developed water access
	▪ Riverside parks	▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect would occur in all nine program reaches.

Effect VEG-6 Finding	With Mitigation
Less than significant	N/A

Effect VEG-7: Opportunity for Habitat Restoration in Enlarged Floodplain Following Program Construction

If the existing levee is removed during installation of the setback levee at the Sacramento River South Levee, the enlarged floodplain created between the water's edge and setback levee area could be dedicated to habitat restoration (e.g., riparian or marsh habitat) and revegetated accordingly. WSAFCA could retain a qualified restoration ecologist or landscape architect to develop a revegetation plan that would ensure the long-term duration of the function and value of the restored habitat. This effect would be beneficial.

Program Alternatives Associated with This Effect

Implementation of this alternative can cause this effect:

Program	Alternative
Flood	▪ Setback levee

Affected Reach

This beneficial effect would occur in the Sacramento South Levee reach if a setback levee treatment were selected.

Effect VEG-7 Finding	With Mitigation
Beneficial	N/A

Section 3.9
Fisheries and Aquatics

3.9.1 Introduction

This section describes the regulatory and environmental setting for fisheries resources and aquatic habitats, the effects on special-status fish species that would result from the proposed program, and the mitigation measures that would reduce these effects.

The key sources of data and information used in the preparation of this section are listed below.

- USFWS list (dated February 4, 2009) of endangered, threatened, and proposed species for the study area (Appendix G)
- Published and unpublished reports
- Field survey on October 26, 2007
- ICF International file information

3.9.2 Affected Environment

3.9.2.1 Regulatory Setting

3.9.2.1.1 Federal

Endangered Species Act

The Federal ESA protects fish and wildlife species and their habitats that have been identified by NMFS or USFWS as threatened or endangered. *Endangered* refers to species, subspecies, or distinct population segments (DPSs) that are in danger of extinction through all or a significant portion of their range. *Threatened* refers to species, subspecies, or DPSs that are likely to become endangered in the near future.

ESA is administered by USFWS and NMFS. In general, NMFS is responsible for protection of ESA-listed marine species and anadromous fish, and USFWS is responsible for other listed species. Provisions of Sections 9 and 7 of ESA are relevant to this program and are summarized below.

Section 9: ESA Prohibitions

Section 9 of the ESA prohibits the take of any fish or wildlife species listed under ESA as endangered. Take of threatened species also is prohibited under Section 9, unless otherwise authorized by Federal regulations.[1] *Take*, as defined by the ESA, means "to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in any such conduct." *Harm* is defined as

[1] In some cases, exceptions may be made for threatened species under ESA Section 4(d); in such cases, USFWS or NMFS issues a "4(d) rule" describing protections for the threatened species and specifying the circumstances under which take is allowed.

"any act that kills or injures the species, including significant habitat modification." In addition, Section 9 prohibits removing, digging up, cutting, and maliciously damaging or destroying federally listed plants on sites under Federal jurisdiction.

Section 7: ESA Authorization Process for Federal Actions

Section 7 of the ESA provides a means for authorizing take of threatened and endangered species by Federal agencies. Under Section 7, the Federal agency conducting, funding, or permitting an action (the lead Federal agency, such as USACE) must consult with NMFS or USFWS, as appropriate, to ensure that the proposed program will not jeopardize endangered or threatened species or destroy or adversely modify designated critical habitat. If a proposed project "may affect" a listed species or designated critical habitat, the lead agency is required to prepare a biological assessment (BA) to evaluate the nature and severity of the expected effect. In response, NMFS or USFWS issues a biological opinion (BO), with a determination that the proposed program either:

- may jeopardize the continued existence of one or more listed species (jeopardy finding) or result in the destruction or adverse modification of critical habitat (adverse modification finding), or
- will not jeopardize the continued existence of any listed species (no jeopardy finding) or result in adverse modification of critical habitat (no adverse modification finding).

The BO issued by NMFS or USFWS may stipulate discretionary "reasonable and prudent" conservation measures. If the project would not jeopardize a listed species, USFWS or NMFS issues an incidental take statement to authorize the proposed activity.

Critical Habitat

Critical habitat, as defined in ESA Section 3, is:

I. the specific area within the geographic area occupied by a species, at the time it is listed in accordance with ESA, on which are found those biological features
    i. essential to the conservation of the species, and
    ii. may require special management considerations or protection; and

II. specific areas outside the geographical area occupied by a species at the time it is listed, upon a determination that such areas are essential for the conservation of the species.

Aquatic habitats in the study area have been designated as critical habitat for the following species:

- Central Valley spring-run Chinook salmon,
- Central Valley winter-run Chinook salmon,
- Central Valley steelhead, and
- Delta smelt.

Clean Water Act

The CWA was enacted as an amendment to the Federal Water Pollution Control Act of 1972, which outlined the basic structure for regulating discharges of pollutants to waters of the United States.

The CWA serves as the primary Federal law protecting the quality of the nation's surface waters, including lakes, rivers, and coastal wetlands.

The CWA empowers EPA to set national water quality standards and effluent limitations and includes programs addressing both point-source and nonpoint-source pollution. Point-source pollution is pollution that originates or enters surface waters at a single, discrete location, such as an outfall structure or an excavation or construction site. Nonpoint-source pollution originates over a broader area and includes urban contaminants in stormwater runoff and sediment loading from upstream areas. The CWA operates on the principle that all discharges into the nation's waters are unlawful unless specifically authorized by a permit; permit review is the CWA's primary regulatory tool. The following sections provide additional details on pertinent sections of the CWA.

Section 404: Permits for Fill Placement in Waters and Wetlands

USACE and EPA regulate the discharge of dredged and fill material into waters of the United States under Section 404 of the CWA. USACE jurisdiction over non-tidal waters of the United States extends to the OHWM, provided the jurisdiction is not extended by the presence of wetlands (33 CFR Part 328, Section 328.4). The OHWM is defined in the Federal regulations to mean:

> [T]hat line on the shore established by the fluctuations of water and indicated by physical characteristics such as clear, natural line impressed on the bank, shelving, changes in the character of soil, destruction of terrestrial vegetation, the presence of litter and debris, or other appropriate means that consider the characteristics of the surrounding areas (33 CFR Part 328, Section 328.3[e]).

USACE typically will exert jurisdiction over that portion of the project site that contains waters of the United States and adjacent or isolated wetlands. This jurisdiction equals approximately the bank-to-bank portion of a creek along its entire length up to the OHWM and adjacent wetland areas that will either be directly or indirectly adversely affected by a proposed project.

Magnuson-Stevens Fishery Conservation and Management Act

The Magnuson-Stevens Fishery Conservation and Management Act (Magnuson-Stevens Act) establishes a management system for national marine and estuarine fishery resources. This legislation requires all Federal agencies to consult with NMFS regarding all actions or proposed actions permitted, funded, or undertaken that may adversely affect essential fish habitat (EFH). EFH is defined as "waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity." The legislation states that migratory routes to and from anadromous fish spawning grounds should also be considered EFH. The phrase "adversely affect" refers to the creation of any effects that reduce the quality or quantity of EFH. Federal activities that occur outside an EFH but that may, nonetheless, have an effect on EFH waters and substrate must also be considered in the consultation process. Under the Magnuson-Stevens Act, effects on habitat managed under the Pacific Salmon Fishery Management Plan must also be considered.

3.9.2.1.2 State

California Endangered Species Act

CESA, which is administered by DFG, protects wildlife and plants listed by the California Fish and Game Commission as threatened and endangered under the act. CESA prohibits all persons from taking species that are state-listed as threatened or endangered except under certain circumstances; the CESA definition of take is any action or attempt to "hunt, pursue, catch, capture, or kill."

CESA Section 2081 provides a means by which agencies or individuals may obtain authorization for incidental take of state-listed species, except for certain species designated as "fully protected" under the California Fish and Game Code. Take must be incidental to, and not the purpose of, an otherwise lawful activity. Requirements for a Section 2081 permit are similar to those used in the ESA Section 7 process. They include identification of effects on listed species, development of mitigation measures that minimize and fully mitigate effects, development of a monitoring plan, and assurance of funding to implement mitigation and monitoring.

California Fish and Game Code Section 1600: Streambed Alteration Agreements

DFG has jurisdictional authority over wetland resources associated with rivers, streams, and lakes under Sections 1600–1607. DFG has the authority to regulate all work under the jurisdiction of the State of California that would substantially divert, obstruct, or change the natural flow of a river, stream, or lake; substantially change the bed, channel, or bank of a river, stream, or lake; or use material from a streambed.

In practice, DFG marks its jurisdictional limit at the top of the stream or lake bank, or the outer edge of the riparian vegetation, where present, and sometimes extends its jurisdiction to the edge of the 100-year floodplain. Because riparian habitats do not always support wetland hydrology or hydric soils, wetland boundaries, as defined by CWA Section 404, sometimes include only portions of the riparian habitat adjacent to a river, stream, or lake. Therefore, jurisdictional boundaries under Section 1600 may encompass a greater area than those regulated under CWA Section 404.

DFG enters into a streambed alteration agreement with an applicant and can impose conditions on the agreement to ensure that no net loss of wetland values or acreage will be incurred. The streambed or lakebed alteration agreement is not a permit, but a mutual agreement between DFG and the applicant.

3.9.2.1.3 Local

City of West Sacramento General Plan

Section VI, Natural Resources Goals and Policies, of the *City of West Sacramento General Plan* identifies policies designed to protect habitat and biological resources that are applicable to the resources located in the study area. The policies listed below are pertinent to fish resources in the project area (City of West Sacramento 2004, II-68-69).

Goal C: To protect sensitive native vegetation and wildlife communities and habitat in West Sacramento

Policies:

2. The City shall support state and Federal policies for preservation and enhancement of riparian and wetland habitats by incorporating, as deemed appropriate, the findings and recommendations of the *Sacramento Greenway Plan*, California Department of Fish and Game and the U.S. Fish and Wildlife Service into site-specific development proposals.

3. The City shall require site-specific surveys to identify significant wildlife habitat and vegetation resources for development projects located in or near riparian or wetland areas.

4. The City shall support mitigation measures which provide for no net loss of riparian or wetland habitat acreage and value by regulating development in and near these habitats and promoting projects that avoid sensitive areas. Where habitat loss is unavoidable, the City shall seek replacement on at least a 1:1 basis. Replacement entails creating habitat that is similar in extent and ecological value to that displaced by the project. The replacement habitat should consist of locally occurring, native species and shall be located as close as possible to the project site or be part of a larger replacement habitat project.

7. The City shall seek to minimize the loss or degradation of wetland and riparian habitats at the following sites: Lake Washington and associated wetlands; Bee Lakes and associated riparian woodlands; riparian woodlands along the Sacramento River north of the I Street Bridge and south of the barge canal; and riparian woodlands along the Deep Water Ship Channel and the Yolo Bypass.

9. The City shall seek to preserve populations of rare, threatened, and endangered species by ensuring that development does not adversely affect such species or by fully mitigating adverse effects.

10. The City shall not approve projects that would cause unmitigable impacts on rare, threatened, or endangered wildlife or plant species.

11. The City shall implement measures to ensure that development in the city does not adversely affect fishery resources in the Sacramento River, Deep Water Ship Channel, and Lake Washington.

12. Public access and recreation facilities shall not eliminate or degrade riparian habitat values. Trails, picnic areas, and other developments shall be sited to minimize impacts on sensitive wildlife habitat or riparian vegetation.

13. The City shall promote the use of native plants, especially valley oaks, for landscaping roadsides, parks, and private properties. In particular, native plants should be used along the Sacramento River and in areas adjacent to riparian and wetland habitats.

Yolo County General Plan

The *Yolo County General Plan* was adopted in 1983. The objective of the general plan is to provide guidance for the development of Yolo County. The general plan promotes the preservation of farm land and open spaces to minimize the area of urbanization. The Open Space and Recreation Element of the general plan was updated in 2002. The following goals, objectives, and policies are relevant to fish resources in the study area:

Goals and Supporting Objectives

- **OG-4:** Protect and manage local water resources.
    - **OO-5:** Provision for open space corridors within existing and future development.
- **OG-5:** Preserve and enhance existing biological resources.
    - **OO-6:** No net loss of wetland and/or riparian habitat.
    - **OO-7:** Maintenance of unique or sensitive plant or animal habitat.

Solano County General Plan

Chapter 4 of the *Solano County General Plan* identifies the following policies with respect to biological resources:

RS.P-1: Protect and enhance the county's natural habitats and diverse plant and animal communities, particularly occurrences of special-status species, wetlands, sensitive natural communities, and habitat connections.

RS.P-5: Protect and enhance wildlife movement corridors to ensure the health and long-term survival of local animal and plant populations.

3.9.2.2 Environmental Setting

This section discusses the existing conditions related to fisheries in the study area.

3.9.2.2.1 Study Area

The proposed program reaches are located in the city of West Sacramento in Yolo County, California, and range in elevation from approximately 15 feet to 25 feet above mean sea level. The study area includes the entire WSAFCA boundary, which encompasses portions of the Sacramento River, the Yolo Bypass, the Sacramento Bypass, and the DWSC. The levee system associated with these waterways includes more than 50 miles of levees in RD 900, RD 537, RD 811, DWR Maintenance Area 4, and the DWSC (Figure 1-2, WSLIP Study Area). These levees completely surround the city.

Sacramento River

The Sacramento River serves as an important migration and juvenile rearing corridor for anadromous fish species, which have been the focus of many restoration programs for the Sacramento River system. Native fish, such as delta smelt and Sacramento splittail, also may spawn in the Sacramento River within the study area along shallow river margins and on adjacent floodplain habitat, when available.

Sacramento River North Levee Reach

The Sacramento River North Levee reach extends along the right bank of the Sacramento River from its confluence with the Sacramento Bypass downstream approximately 6.0 miles to the entrance to the barge canal. This section of the Sacramento River provides migratory habitat for anadromous fish such as steelhead, Chinook salmon, river lamprey, and green sturgeon. This reach contains riparian vegetation and shaded riverine aquatic (SRA) cover.

Sacramento River South Levee Reach

The Sacramento River South Levee reach extends along the right bank of the Sacramento River from the entrance of the barge canal downstream approximately 6.4 miles to the South Cross Levee. This section of the Sacramento River provides migratory habitat for anadromous fish such as steelhead, Chinook salmon, river lamprey, and green sturgeon. Riparian vegetation and SRA cover occur in this reach, although vegetation is less dense than it is in the Sacramento River North Levee reach.

Sacramento and Yolo Bypasses

The Sacramento and Yolo Bypasses provide emigration and rearing habitat for juvenile anadromous fish and spawning and rearing habitat for splittail. The occurrence of these life stages in the Sacramento and Yolo Bypasses is limited mainly to periods when flooding (via the Fremont and Sacramento Weirs) allows individuals to access the area from the Sacramento River. Sacramento splittail and juvenile Chinook salmon have been captured in the Sacramento Bypass (Jones & Stokes 2001). The Yolo Bypass seasonally provides habitat for delta smelt, splittail, steelhead, and Chinook salmon (Sommer et al. 2001). Most juveniles emigrate from the Sacramento and Yolo Bypasses during winter and spring before the floodplains become dry. Thus, the potential for these species' life stages to occur in these areas in any given year depends on the occurrence of flooding; the timing, magnitude, and duration of flooding; and the seasonal timing of specific life stages. However, the occurrence of these species is not limited to periods when the bypasses are flooded. In a trapping study at the Yolo Bypass Toe Drain, a perennial tidal channel that runs along the east side of the Yolo Bypass and drains adjacent fields, Harrell and Sommer (2003) found that adult Chinook salmon and white sturgeon (among a suite of other native and introduced fish species) occur in the toe drain even in years when the bypasses are not flooded.

Sacramento Bypass Levee Reach

The Sacramento Bypass Levee reach extends along the left bank of the Sacramento Bypass, approximately 1.2 miles from the Sacramento Weir, in a westerly direction (downstream) to its confluence with the left bank levee of the Yolo Bypass. This reach does not include the training levee that extends in a westerly direction approximately 0.4 mile into the Yolo Bypass.

This reach provides migratory and rearing habitat for emigrating juvenile salmonids, green sturgeon, and river lamprey when inundated during high winter and spring flows. Sacramento splittail also use the Sacramento Bypass for spawning and juvenile rearing. This reach is a floodplain habitat that is covered with terrestrial vegetation. No SRA cover occurs in this reach.

Yolo Bypass Levee Reach

The Yolo Bypass Levee reach extends along the east bank of the Yolo Bypass, approximately 3.8 miles from its intersection with the east bank levee of the Sacramento Bypass, in a southerly direction to its intersection with the DWSC West Levee.

The Yolo Bypass provides migratory and rearing habitat for emigrating juvenile salmonids, green sturgeon, and river lamprey when inundated during high winter and spring flows. Sacramento splittail also use the Yolo Bypass for spawning and juvenile rearing. The toe drain is in this reach and has little SRA cover.

Deep Water Ship Channel

The DWSC, which was constructed in 1963 to accommodate deep-draft ocean-going vessels, does not support spawning, rearing, or migratory habitat for special-status fish species. However, anadromous fish do stray into the DWSC because of its downstream connection with, and proximity to, the Sacramento River. Steelhead and Chinook salmon have been captured by DFG during intermittent studies in the DWSC (National Marine Fisheries Service n.d.). Fish that stray into the DWSC are unable to continue migrating upstream into the Sacramento River because the locks at the barge canal are permanently closed, and no fish passage facilities currently exist.

Port North Levee Reach

The Port North Levee reach includes the combination of levees, structures, and high ground along the northern bank of the barge canal and the DWSC channel from the Sacramento River west to the levee along the left bank of the Yolo Bypass. This area includes the ground surrounding the Port of West Sacramento's turning basin. This reach is highly channelized, with low-value rearing and migratory fish habitat, and sparse riparian vegetation and SRA cover.

Special-status fish can stray into the easternmost portion of the barge canal from the mainstem of the Sacramento River but are blocked from further migration up the barge canal and into the DWSC by the barge locks. During upstream migration, special-status fish could stray into the DWSC from the mainstem of the Sacramento River via Cache Slough and have access to the habitat along the westernmost portion of the Port North Levee. These special-status fish species include steelhead, Chinook salmon, river lamprey, and green sturgeon.

Port South Levee Reach

The Port South Levee reach includes the combination of levees and high ground along the southern bank of the barge canal and the DWSC from the Sacramento River west to the levee on the east bank of the DWSC. The same fish and migratory and rearing habitat occur as in the Port North Levee reach. This reach is highly channelized, and riparian vegetation and SRA cover are sparse.

Deep Water Ship Channel West Levee Reach

The DWSC West reach extends along the east bank of the Yolo Bypass, approximately 22 miles from its intersection with the western limit of the Port North Levee, in a southerly direction to Miners Slough. The same fish and migratory and rearing habitat occur as in the Port North Levee reach. The DWSC is highly channelized with no SRA cover.

Deep Water Ship Channel East Levee Reach

The DWSC East reach extends along the east bank of the DWSC, approximately 2.8 miles from the high ground making up the western limit of the Port South Levee reach, in a southerly direction to the intersection of Jefferson Boulevard with the South Cross Levee. The DWSC is highly channelized with no SRA cover. Fish migration through the DWSC to the Sacramento River is blocked by the barge locks.

South Cross Levee Reach

This reach extends for approximately 1.2 miles from the intersection of Jefferson Boulevard and the levee along the east bank of the DWSC to the Sacramento River where it intersects the southern limit of the Sacramento River South Levee reach. There is a drainage for runoff from the housing development in this reach, but it does not connect with the Sacramento River or the DWSC. No special-status fish species habitat occurs in this reach.

3.9.2.2.2 Aquatic Habitats

Aquatic habitats in the study area consist of perennial, intertidal, and seasonal habitats. Fish and other species use these habitats for growth, survival, and reproduction. Fish use these habitats differently, depending on species and life stage. Many different aquatic habitats exist in the study

area and can be characterized as nearshore and SRA cover, open water (pelagic), and floodplain. These habitats are described in greater detail below.

Nearshore and Shaded Riverine Aquatic Cover

Nearshore areas support large and diverse fish and wildlife populations. These areas are important to fish for rearing and migration because they create attachment sites for aquatic insects (a food source for fish) and provide fish with shelter from predators. For example, juvenile Chinook salmon and steelhead rely on nearshore habitats as fry, smolt, or yearlings and to some extent as adults. In addition, vegetated nearshore habitat can also provide spawning areas for some fish species, such as splittail, delta smelt, black bass, and sunfish. Riparian vegetation is a component of nearshore and SRA cover and directly influences the quality of fish habitat. Its presence has an effect on cover, food, instream habitat complexity, streambank stability, and temperature regulation. Large woody debris usually originates from riparian trees and provides habitat complexity in aquatic environments, an essential component of fish habitat. The roots of riparian vegetation at the land-water interface and on adjacent berms provide streambank stability and cover for rearing fish. (Meehan and Bjorn 1991.)

Cover describes the physical components of a stream environment that provide shelter and hiding, resting, rearing, holding, and feeding areas for fish and other aquatic organisms. Gravel, cobbles, boulders, ledges, undercut banks, aquatic plants, saplings, brush, trees, and instream woody material (e.g., tree limbs, logs, rootwads) all provide cover. The quantity and quality of cover for fish and aquatic invertebrates is a primary determinant of habitat availability and suitability. The occurrence of many aquatic species, including juvenile salmonids, depends on the size, density, and continuity of suitable cover.

Riparian vegetation also provides shade and an insulating canopy that moderates water temperatures in both summer and winter. While the influence of shade on regulating river temperatures decreases as rivers become larger, the moderating effects of shade on nearshore water temperatures may be important to some fish species, including juvenile salmonids, during the growing season.

Riparian vegetation also influences the food chain of a stream, providing organic detritus and terrestrial insects. Terrestrial organisms falling from overhanging branches contribute to the food base of the aquatic community. Salmonids in particular are primarily insectivores and feed mainly on drifting food organisms.

Habitat complexity of nearshore and SRA cover areas within the study area is variable and depends on the amount of adjacent riparian vegetation. Along the margins of the Sacramento River and toe drain, and where extensive riparian vegetation borders aquatic habitats, the extent of SRA cover is high. In contrast, riparian vegetation and SRA cover along the DWSC are relatively scarce because most of the shoreline is covered with riprap or maintained to control vegetation growth.

Open Water

Open water habitat includes areas of the Sacramento River channel, DWSC, and toe drain that are free of instream structure, such as vegetation and instream woody material, and away from the shoreline. Typically, open-water habitats have greater water depths and water velocities than nearshore habitat.

Delta smelt and striped bass are found primarily in open-water habitat. In addition, adult and juvenile salmonids use mid-channel areas for migration.

Floodplain

Recognition is growing that naturally functioning floodplains provide many benefits, including direct economic benefits, ecosystem services, and habitat for a wide diversity of species (Bayley 1991; Tockner and Stanford 2002, as cited in Ahearn et al. 2006). Floodplains provide freshwater habitat for the migration, reproduction, and rearing of native fishes (Moyle et al. 2003; Crain et al. 2004) and mitigate flood damage to human settlements (Sommer et al. 2001a).

Floodplains are highly productive habitats that flood during high flows in the winter and spring. Floodplains are important habitats for young fish, especially Chinook salmon and splittail (Moyle et al. 2005). Chinook salmon, which spawn in freshwater rivers and streams upstream of the Delta, use inundated floodplain habitats (when available) for rearing. Chinook salmon growth has been shown to be faster in floodplain habitat than in river systems (Sommer et al. 2001b). Sacramento splittail, which spawn in inundated floodplains, produce the highest numbers of young when flows are high and floodplain habitat is inundated (Moyle 2002).

3.9.2.2.3 Special-Status Fish Species

The special-status fish species listed below have the potential to occur in the study area.

- Sacramento River winter-run Chinook salmon Evolutionarily Significant Unit (ESU) (*Oncorhynchus tshawytscha*)—FE/SE.
- Central Valley spring-run Chinook salmon ESU (*O. tshawytscha*)—FT/ST.
- Central Valley fall-/late fall–run Chinook salmon ESU (*O. tshawytscha*)—FSC/SSC.
- Central Valley steelhead DPS (*O. mykiss*)—FT.
- Southern DPS of North American green sturgeon (*Acipenser medirostris*)—FT/SSC.
- Delta smelt (*Hypomesus transpacificus*)—FT/ST.
- Sacramento splittail (*Pogonichthys macrolepidotus*)—SSC.
- River lamprey (*Lampetra ayresi*)—SSC.

Special-status fish species that occur or have the potential to occur in or near the study area, as well as their likely status in the study area, are presented in Table 3.9-1. Critical habitat for winter and spring-run Chinook salmon and Central Valley steelhead falls within the study area in the Sacramento River. In addition, the Sacramento and Yolo Bypasses are designated critical habitat for Central Valley steelhead (70 FR 52612:52617 September 2, 2005) and spring-run Chinook salmon (70 FR 52597:52601 September 2, 2005). Critical habitat for delta smelt includes the Sacramento River and the Yolo Bypass upstream to the I Street Bridge (U.S. Fish and Wildlife Service 2003).

Table 3.9-1. Special-Status Fish Species with Potential to Occur in the Study Area

Common and Scientific Name	Status[a] Federal/State	California Distribution	Habitats	Occurrence in the Study Area
Delta smelt *Hypomesus transpacificus*	T/T	Primarily in the Sacramento–San Joaquin Estuary, but has been found as far upstream as the mouth of the American River on the Sacramento River and Mossdale on the San Joaquin River; range extends downstream to San Pablo Bay	Occurs in estuary habitat in the Delta where fresh and brackish water mix in the salinity range of 2–7 parts per thousand (Moyle 2002).	High
Sacramento splittail *Pogonichthys macrolepidotus*	–/SSC	Occurs throughout the year in low-salinity waters and freshwater areas of the Sacramento–San Joaquin Delta, Yolo Bypass, Suisun Marsh, Napa River, and Petaluma River (Moyle 2002).	Spawning takes place among submerged and flooded vegetation in sloughs and the lower reaches of rivers.	High
Central Valley steelhead *Oncorhynchus mykiss*	T/–	Sacramento River and tributary Central Valley rivers	Occurs in well-oxygenated, cool, riverine habitat with water temperatures from 7.8 to 18°C (Moyle 2002). Habitat types are riffles, runs, and pools.	High—spawning during migration
Sacramento River winter-run Chinook salmon *Oncorhynchus tshawytscha*	E/E	Mainstem Sacramento River below Keswick Dam (Moyle 2002)	Occurs in well-oxygenated, cool, riverine habitat with water temperatures from 8.0 to 12.5°C. Habitat types are riffles, runs, and pools. (Moyle 2002.)	High—spawning during migration
Central Valley spring-run Chinook salmon *Oncorhynchus tshawytscha*	T/T	Upper Sacramento River and Feather River	Has the same general habitat requirements as winter-run Chinook salmon. Coldwater pools are needed for holding adults (Moyle 2002).	High—spawning during migration
Central Valley fall-/late fall–run Chinook salmon *Oncorhynchus tshawytscha*	SC/SSC	Sacramento and San Joaquin Rivers and tributary Central Valley rivers	Occurs in well-oxygenated, cool, riverine habitat with water temperatures from 8.0 to 12.5°C. Habitat types are riffles, runs, and pools (Moyle 2002).	High—spawning during migration

Common and Scientific Name	Status[a] Federal/State	California Distribution	Habitats	Occurrence in the Study Area
Green sturgeon (southern DPS) *Acipenser medirostris*	T/SSC	Sacramento, Klamath and Trinity Rivers (Moyle 2002)	Spawn in large river systems with well-oxygenated water, with temperatures from 8.0 to 14°C	High—spawning during migration
River lamprey *Lampetra ayresi*	–/SSC	Sacramento, San Joaquin, and Napa Rivers; tributaries of San Francisco Bay (Moyle 2002; Moyle et al. 1995)	Adults live in the ocean and migrate into fresh water to spawn	High—spawning during migration

[a] Species Definitions

Federal

E = endangered under the Federal Endangered Species Act
T = threatened under the Federal Endangered Species Act
SC = species of concern
– = no listing

State

E = endangered under the California Endangered Species Act
T = threatened under the California Endangered Species Act.
SSC = species of special concern
– = no listing

1

Chinook Salmon

Chinook salmon are anadromous fish, meaning that adults live in marine environments and return to their natal freshwater streams to spawn. Juveniles rear in freshwater for a period of up to 1 year until smoltification (i.e., a physiological preparation for survival in marine environs) and subsequent ocean residence.

Four distinct runs of Chinook salmon occur in the Sacramento River system: winter-run, spring-run, fall-run, and late fall–run. The runs are named after the season of adult migration, with each run having a distinct combination of adult migration, spawning, juvenile residency, and smolt migration periods. In general, fall- and late fall-run Chinook salmon spawn soon after entering their natal streams, while spring- and winter-run Chinook salmon typically hold in their natal streams for up to several months before spawning.

Winter-Run

Both the ESA and CESA list the winter-run Chinook salmon ESU as an endangered species. Critical habitat for winter-run Chinook salmon includes the Sacramento River from Keswick Dam (RM 302) to Chipps Island (RM 0) in the Delta (National Marine Fisheries Service 1997).

Historically, winter-run Chinook salmon spawned in cold tributary streams upstream of present-day Shasta Reservoir, including the Little Sacramento, Pit, McCloud, and Fall Rivers and Battle Creek. Presently, winter-run Chinook salmon persist in the Sacramento River below Keswick Dam and are sustained by coldwater releases from Shasta Reservoir.

Adult winter-run Chinook salmon immigration (upstream migration) through the Delta and into the Sacramento River occurs from December through July, with peak immigration from January through April. Winter-run Chinook salmon spawn primarily in the mainstem Sacramento River between Keswick Dam (RM 302) and the Red Bluff Diversion Dam (RM 242). Winter-run Chinook salmon spawn between late April and mid-August, with peak spawning generally occurring in June (Snider et al. 2000) (Table 3.9-2).

Juvenile emigration (downstream migration) past the Red Bluff Diversion Dam (RM 242) begins in late July, peaks during September, and may extend through mid-March (National Marine Fisheries Service 1997). The peak period of juvenile emigration through the lower Sacramento River into the Delta generally occurs between January and April (National Marine Fisheries Service 1997) (Table 3.9-2). Differences in peak emigration periods between these two locations suggest that juvenile winter-run Chinook salmon may exhibit a sustained residence in the upper or middle reaches of the Sacramento River before entering the lower Sacramento River and the Delta. Although the location and extent of rearing in these lower or middle reaches is unknown, it is believed that the duration of fry presence in an area is directly related to the magnitude of river flows during the rearing period (Stevens 1989). Additional information on life history and habitat requirements is available in the NMFS BO, which was developed specifically to evaluate effects on winter-run Chinook salmon associated with Central Valley Project (CVP) and State Water Project (SWP) operations (National Marine Fisheries Service 1993).

Spring-Run

The Central Valley spring-run Chinook salmon ESU, which includes populations spawning in the Sacramento River and its tributaries, is listed as threatened under ESA and CESA. Critical habitat is

designated for spring-run Chinook salmon in the Sacramento River, but the Sacramento DWSC is excluded from the critical habitat designation (70 FR 52596).

Spring-run Chinook salmon historically occurred from the upper tributaries of the Sacramento River to the upper tributaries of the San Joaquin River. However, they have been extirpated from the San Joaquin River system. The only streams in the Central Valley with remaining wild spring-run Chinook salmon populations are the Sacramento River and its tributaries, including the Yuba River, Mill Creek, Deer Creek, and Butte Creek.

Spring-run Chinook salmon enter the Sacramento River from late March through September (Reynolds et al. 1993), but peak abundance of immigrating adults in the Delta and lower Sacramento River occurs from April through June (Table 3.9-2). Adult spring-run Chinook salmon remain in deep-water habitats downstream of spawning areas during summer until their eggs fully develop and become ready for spawning. This is the primary characteristic that distinguishes spring-run Chinook salmon from the other runs. Spring-run Chinook salmon spawn primarily upstream of the Red Bluff Diversion Dam and in the aforementioned tributaries. Spawning occurs from mid-August through early October (Reynolds et al. 1993) (Table 3.9-2). A small portion of an annual year-class may emigrate as post-emergent fry (less than 1.8 inches long) and reside in the Delta undergoing smoltification. However, most are believed to rear in the upper river and tributaries during winter and spring, emigrating as juveniles (more than 1.8 inches long). The timing of juvenile emigration from the spawning and rearing reaches can vary depending on tributary of origin and can occur from November through June (Table 3.9-2).

Fall- and Late Fall-Run

Central Valley fall-run and late fall–run Chinook salmon are commercially and recreationally important. These ESUs are Federal species of concern. Because the fall-run Chinook salmon is currently the largest run of Chinook salmon in the Sacramento River system, it continues to support commercial and recreational fisheries of significant economic importance.

All Central Valley streams that had adequate flows in the fall, even if they were intermittent during the summer, probably supported fall-run Chinook salmon. Unlike spring- and winter-run Chinook salmon that migrated to higher elevation streams, fall-run Chinook salmon likely were limited to streams of the valley floor and lower foothill reaches because of their egg-laden and generally deteriorated physical condition.

In general, adult fall-run Chinook salmon migrate into the Sacramento River and its tributaries from July through December, with immigration peaking from mid-October through November (Table 3.9-2). Fall-run Chinook salmon spawn in numerous tributaries of the Sacramento River, including the lower American River, lower Yuba River, Feather River, and tributaries of the upper Sacramento River. Most mainstem Sacramento River spawning occurs between Keswick Dam and the Red Bluff Diversion Dam. A greater extent of fall-run spawning, relative to the other three runs, occurs below the Red Bluff Diversion Dam, with limited spawning potentially occurring as far downstream as Tehama (RM 220) (Yoshiyama et al. 1996). Spawning generally occurs from October through December, with fry emergence typically beginning in late December and January (Table 3.9-2). Fall-run Chinook salmon emigrate as post-emergent fry, juveniles, and smolts after rearing in their natal streams for up to 6 months. Consequently, fall-run emigrants may be present in the lower Sacramento River from January through June (Reynolds et al. 1993) (Table 3.9-2) and remain in the Delta for variable lengths of time before ocean entry.

Adult immigration of late fall-run Chinook salmon into the Sacramento River generally begins in October, peaks in December, and ends in April (Moyle et al. 1995) (Table 3.9-2). Primary spawning areas for late fall-run Chinook salmon are located in tributaries of the upper Sacramento River (e.g., Battle Creek, Cottonwood Creek, Clear Creek, Mill Creek), although late fall-run Chinook salmon are believed to return to the Feather and Yuba Rivers as well (Moyle et al. 1995). Spawning in the mainstem Sacramento River occurs primarily from Keswick Dam (RM 302) to the Red Bluff Diversion Dam (RM 258), generally from January through April (Moyle et al. 1995). Juveniles emigrate through the lower Sacramento River primarily from October through April (Table 3.9-2).

Central Valley Steelhead

Central Valley steelhead is listed as threatened under the ESA. Critical habitat is designated for steelhead in the Sacramento River, but the Sacramento DWSC is excluded from the critical habitat designation (70 FR 52596). Steelhead, an anadromous variant of rainbow trout, is closely related to Pacific salmon. The species was once abundant in California coastal and Central Valley drainages. However, population numbers have declined significantly in recent years, especially in the tributaries of the Sacramento River. Steelhead typically migrate to marine waters after spending 1 year or more in fresh water. In the marine environment, they typically mature for 1 to 3 years before returning to their natal streams to spawn as 3- or 4-year-olds. Unlike Pacific salmon, steelhead are capable of spawning more than once before they die. Immigration of adult steelhead in the Sacramento River occurs in nearly all months but peaks in late September and October (Moyle 2002). The steelhead spawning season typically stretches from December through April (Table 3.9-2). After several months, fry emerge from the gravel and begin to feed. Juveniles rear in fresh water from 1 to 4 years (usually 2 years), then migrate to the ocean as smolts in the spring (March through June).

Sacramento Splittail

Sacramento splittail is a California species of special concern. Sacramento splittail is an endemic California minnow that was once widely distributed in lakes and rivers throughout the Central Valley, including the Sacramento River upstream to Redding and the American River as far east as Folsom (Moyle 2002). Present distribution includes Suisun Bay, the Napa and Petaluma Rivers (Sommer et al. 1997), the Sacramento River as far north as the Red Bluff Diversion Dam, portions of the Delta, and the San Joaquin River upstream of its confluence with the Tuolumne River (Moyle 2002).

Adult splittail usually reach sexual maturity in their second year. They then migrate upstream in late fall to early winter before spawning. Spawning occurs from mid-winter through July in water temperatures between 48°F and 68°F (Wang 1986) at times of high winter or spring runoff (Moyle et al. 1995). Eggs acquire adhesive properties following exposure to water and adhere to vegetation or other benthic substrates (Wang 1986). Fertilized eggs generally hatch in 3 to 5 days, and larvae begin feeding on plankton soon thereafter. Juvenile splittail inhabit shallow areas with abundant vegetation that are devoid of strong currents (Wang 1986) as they travel downstream from the spawning grounds to the Delta.

Mature splittail are generally found in the shallows of sloughs in edgewater habitat by emergent vegetation. They feed primarily on benthic invertebrates and aquatic insect larvae (Moyle 2002). Although they are tolerant of brackish water (Moyle 2002), splittail tend to move from areas of relatively high salinity to those characterized by fresh water (Moyle et al. 1995).

Delta Smelt

Delta smelt are listed as threatened under the ESA and CESA. Critical habitat is designated from the Delta into the Sacramento River. Estuarine rearing habitat for juvenile and adult delta smelt is typically found in the waters of the lower Delta and Suisun Bay where salinity is between 2 and 7 parts per thousand (ppt). Delta smelt tolerate 0 to 19 ppt salinity. They typically occupy open shallow waters but also occur in the main channel in the region where fresh and brackish water mix. The zone may be hydraulically conducive to their ability to maintain position and metabolic efficiency (Moyle 2002).

Adult delta smelt begin spawning migration into the upper Delta in December or January (Table 3.9-2). Migration may continue over several months. Spawning occurs between January and July, with peak spawning during April through mid-May (Moyle 2002) (Table 3.9-2). Spawning occurs along the channel edges in the upper Delta, including the Sacramento River above Rio Vista, Cache Slough, Lindsey Slough, and Barker Slough. Spawning has been observed in the Sacramento River up to Garcia Bend during drought conditions, possibly attributable to adult movement farther inland in response to saltwater intrusion (Wang and Brown 1993). Eggs are broadcast over the river bottom where they attach to firm substrate, woody material, and vegetation. Hatching takes approximately 9 to 13 days, and larvae begin feeding 4 to 5 days later. Newly hatched larvae contain a large oil globule and are semi-buoyant. Larval smelt feed on rotifers and other zooplankton. As their fins and swim bladder develop, they move higher into the water column. Larvae and juveniles gradually move downstream toward rearing habitat in the estuarine mixing zone (Wang 1986).

Green Sturgeon

NMFS has divided sturgeon into two DPSs: the southern and northern DPS. The northern DPS comprises sturgeon from the Eel River northward; the southern DPS comprises populations below the Eel, specifically the Sacramento River population (71 FR 17757). The southern DPS, which occurs in the study area, is federally listed as threatened (71 FR 17757, April 7, 2006). Green sturgeon are known to occur in the lower reaches of large rivers, including the Klamath, Eel, and Smith Rivers from the Delta northward (Moyle 2002). Green sturgeon also have been found in saltwater from Ensenada, Mexico, to the Bering Sea and Japan (Miller and Lea 1972). Adults of this species tend to be associated with marine environments more than the more common white sturgeon, although spawning populations have been identified in the Sacramento and Klamath Rivers (Beak Consultants 1993). Virtually all green sturgeon spawning occurs upstream of Hamilton City and as far upstream as Keswick Dam (Adams et al. 2002). Green sturgeon are thought to spawn upstream of the Red Bluff Diversion Dam following modifications to the operation of that facility (Adams et al. 2002). The preferred spawning substrate is thought to be large cobble, although the substrate type may range from clean sand to bedrock. Eggs are broadcast and fertilized in relatively fast-flowing water where depths typically exceed 10 feet (Moyle 2002). In the Sacramento River, green sturgeon presumably spawn at temperatures ranging from 46°F to 57°F (Beak Consultants 1993).

River Lamprey

River lamprey is a state species of special concern. River lamprey are relatively small (averaging 6.7 inches long) and highly predaceous (Moyle 2002). They are anadromous and will attack fish in both fresh and saltwater (Moyle 2002). A great deal of what is known about the species is based on populations in British Columbia. There, adults migrate from the Pacific Ocean into rivers and

streams in September and spawn in winter. Adults excavate a saucer-shaped depression in sand or gravel riffles where eggs are deposited. After spawning, the adults perish. Juvenile river lamprey, called ammocoetes, remain in backwaters for several years where they feed on algae and microorganisms (Moyle et al. 1986). The metamorphosis from juvenile to adult begins in July and is complete by the following April. From May through July, following completion of metamorphosis, river lamprey aggregate in the Delta before entering the ocean.

River lamprey is distributed in streams and rivers along the eastern Pacific Ocean from Juneau, Alaska, to San Francisco Bay. It may have its greatest abundance in the Sacramento and San Joaquin River systems, although it is not commonly observed in large numbers (Moyle et al. 1986).

Table 3.9-2. Life Stage Timing and Distribution of Selected Species Potentially Affected by the Proposed Program

3.9.2.2.4 Factors that Affect Abundance of Fish Species

Information relating abundance with environmental conditions is most available for listed species, especially Chinook salmon. The following section focuses on factors that have potentially affected the abundance of listed species in the Central Valley. Although not all species are discussed, factors affecting the listed species are assumed also to affect the abundance of other native and non-native species in similar fashion.

Spawning Habitat Area

Spawning habitat area may limit the production of juveniles and subsequent adult abundance of some species. Spawning habitat area for fall- and late fall–run Chinook salmon, which compose more than 90% of the Chinook salmon returning to the Central Valley streams, has been identified as limiting their population abundance. Existing spawning habitat area has not been identified as a limiting factor for the less-abundant winter-run and spring-run Chinook salmon (National Marine Fisheries Service 1996; U.S. Fish and Wildlife Service 1996), although habitat may be limiting in some streams (e.g., Butte Creek) during years of high adult abundance.

Delta smelt spawn in fresh water at low tide on aquatic, submerged, and inshore plants and over sandy and hard bottom substrates of sloughs and shallow edges of channels in the upper Delta and Sacramento River above Rio Vista (Wang 1986; Moyle 2002). Spawning habitat area has not been identified as a factor affecting delta smelt abundance (U.S. Fish and Wildlife Service 1996), but little is known about specific spawning areas and requirements in the Delta.

A lack of sufficient seasonally flooded vegetation may limit splittail spawning success (Young and Cech 1996; Sommer et al. 1997). Splittail spawn over flooded vegetation and debris on floodplains inundated by high flows from February to early July in the Sacramento River and San Joaquin River systems. The onset of spawning appears to be associated with rising water levels, increasing water temperature, and day length (Moyle 2002). The Sutter and Yolo Bypasses along the Sacramento River are important spawning habitat areas during high flow.

Rearing Habitat Area

Rearing habitat area may limit the production of juveniles and subsequent adult abundance of some species. USFWS (1996) has indicated rearing habitat area in Central Valley streams and rivers limits the abundance of juvenile fall-run and late fall–run Chinook salmon and juvenile steelhead. Rearing habitat for salmonids is defined by environmental conditions such as water temperature, dissolved oxygen (DO), turbidity, substrate, water velocity, water depth, and cover (Jackson 1992; Bjornn and Reiser 1991; Healey 1991). Chinook salmon also rear along the shallow vegetated edges of Delta channels (Grimaldo et al. 2000).

Environmental conditions and interactions among individuals, predators, competitors, and food sources determine habitat quantity and quality and the productivity of the stream (Bjornn and Reiser 1991). Everest and Chapman (1972) found juvenile Chinook salmon and steelhead of the same size using similar in-channel rearing area.

Rearing area varies with flow. High flow increases the area available to juvenile Chinook salmon because they extensively use submerged terrestrial vegetation on the channel edge and the floodplain. Deeper inundation provides more overhead cover and protection from avian and terrestrial predators than shallow water (Everest and Chapman in Jackson 1992). In broad, low-gradient rivers, change in flow can greatly increase or decrease the lateral area available to juvenile Chinook salmon, particularly in riffles and shallow glides (Jackson 1992).

Rearing habitat for larval and early juvenile delta smelt encompasses the lower reaches of the Sacramento River below Isleton and the San Joaquin River below Mossdale. Estuarine rearing by juveniles and adults occurs in the lower Delta and Suisun Bay. USFWS (1996) has indicated that loss of rearing habitat area would adversely affect the abundance of larval and juvenile delta smelt. The area and quality of estuarine rearing habitat are assumed to be dependent on the downstream location of approximately 2 ppt salinity (Moyle et al. 1992). The condition where 2 ppt salinity is located in the Delta is assumed to provide less habitat area and lower quality than the habitat provided by 2 ppt salinity located farther downstream in Suisun Bay. During years of average and high outflow, delta smelt may concentrate anywhere from the Sacramento River around Decker Island to Suisun Bay (Moyle 2002). This geographic distribution may not always be a function of outflow and 2 ppt isohaline position. Outflow and the position of the 2 ppt isohaline may account for only about 25% of the annual variation in abundance indices for delta smelt (California Department of Water Resources and Bureau of Reclamation 1994).

Rearing habitat has not been identified as a limiting factor in splittail population abundance, but as with spawning, a lack of sufficient seasonally flooded vegetation may be limiting population abundance and distribution (Young and Cech 1996). Rearing habitat for splittail encompasses the Delta, Suisun Bay, Suisun Marsh, the lower Napa River, the lower Petaluma River, and other parts of San Francisco Bay (Moyle 2002). In Suisun Marsh, splittail concentrate in the dead-end sloughs that have small streams feeding into them (Daniels and Moyle 1983; Moyle 2002). As splittail grow,

salinity tolerance increases (Young and Cech 1996). Splittail are able to tolerate salinity concentrations as high as 29 ppt and as low as 0 ppt (Moyle 2002).

Migration Habitat Conditions

The Sacramento River and the Delta provide a migration pathway between freshwater and ocean habitats for adult and juvenile steelhead and all runs of Chinook salmon.

Migration habitat conditions include streamflows that provide suitable water velocities and depths that provide successful passage. Flow in the Sacramento River and in the Delta provides the necessary depth, velocity, and water temperature; however, flow and environmental conditions in the Central Valley are not always at optimal levels (e.g., see discussion below for water temperature). In the Delta, the channel pathways affect migration of juvenile Chinook salmon. Juvenile Chinook salmon survival is lower for fish migrating through the central Delta (i.e., diverted into the Delta Cross Channel and Georgiana Slough) than for fish continuing down the Sacramento River (Newman and Rice 1997). Similarly, juvenile Chinook salmon entering the Delta from the San Joaquin River appear to have higher survival rates if they remain in the San Joaquin River channel instead of moving into Old River and the south Delta (Brandes and McLain 2001).

Larval and early juvenile delta smelt are transported by currents that flow downstream into the upper end of the mixing zone of the estuary where incoming saltwater mixes with outflowing fresh water (Moyle et al. 1992). Reduced flow may adversely affect transport of larvae and juveniles to rearing habitat.

Adult splittail gradually move upstream during the winter and spring months to spawn. Year-class success of splittail is positively correlated with wet years, high Delta outflow, and floodplain inundation (Sommer et al. 1997; Moyle 2002). Low flow impedes access to floodplain areas that support rearing and spawning.

Water Temperature

Fish species have different responses to water temperature conditions depending on their physiological adaptations. Salmonids in general have evolved under conditions in which water temperatures need to be relatively cool. Delta smelt and splittail can tolerate warmer temperatures. In addition to species-specific thresholds, different life stages have different water temperature requirements. Eggs and larval fish are the most sensitive to warm water temperature.

Unsuitable water temperatures for adult salmonids such as Chinook salmon and steelhead during upstream migration lead to delayed migration and the potential for lower reproduction rates. Elevated summer water temperatures in holding areas cause mortality of spring-run Chinook salmon (U.S. Fish and Wildlife Service 1996). Warm water temperature and low DO also increase egg and fry mortality. USFWS (1996) cited elevated water temperatures as limiting factors for fall- and late fall-run Chinook salmon.

Juvenile salmonid survival, growth, and vulnerability to disease are affected by water temperature. In addition, water temperature affects prey species abundance and predator occurrence and activity. Juvenile salmonids alter their behavior depending on water temperature, including movement to take advantage of local water temperature refugia (e.g., movement into stratified pools, shaded habitat, subsurface flow) and improve feeding efficiency (e.g., movement into riffles).

Water temperature in Central Valley rivers frequently exceeds the tolerance of Chinook salmon and steelhead life stages. For example, adult fall-run Chinook salmon have been observed to stop their upstream migration when water temperatures exceed 66°F (Hallock et al. 1970). For Chinook salmon eggs and larvae, survival during incubation is assumed to decline with increasing temperature between 54°F and 61°F (Myrick and Cech 2001; Seymour 1956 in Alderice and Velsen 1978). For juvenile Chinook salmon, survival is assumed to decline as temperature warms from 64°F to 75°F (Myrick and Cech 2001; Rich 1987). Relative to rearing, Chinook salmon require cooler temperatures to complete the parr-smolt transformation and maximize their saltwater survival. Successful smolt transformation is assumed to deteriorate at temperatures ranging from 63°F to 73°F (Marine 1997 in Myrick and Cech 2001; Baker et al. 1995).

For steelhead, successful adult migration and holding are assumed to deteriorate as water temperature warms between 52°F and 70°F. Adult steelhead appear to be much more sensitive to thermal extremes than are juveniles (National Marine Fisheries Service 1996; McCullough 1999). Conditions supporting steelhead spawning and incubation are assumed to deteriorate as temperature warms between 52°F and 59°F (Myrick and Cech 2001). Juvenile rearing success is assumed to deteriorate at water temperatures ranging from 63°F to 77°F (Raleigh et al. 1984; Myrick and Cech 2001). Relative to rearing, smolt transformation requires cooler temperatures, and successful transformation occurs at temperatures ranging from 43°F to 50°F. Juvenile steelhead, however, have been captured at Chipps Island in June and July at water temperatures exceeding 68°F (Nobriga and Cadrett 2001). Juvenile Chinook salmon have also been observed to migrate at water temperatures warmer than expected based on laboratory experimental results (Baker 1995).

Delta smelt and splittail populations are adapted to water temperature conditions in the Delta. Delta smelt may spawn at temperatures as high as 72°F (U.S. Fish and Wildlife Service 1996) and can rear and migrate at temperatures as warm as 82°F (Swanson and Cech 1995). Splittail may withstand temperatures as warm as 91°F but prefer temperatures between 66°F and 75°F (Young and Cech 1996).

Entrainment

All fish species are entrained to varying degrees by the SWP and CVP Delta export facilities and many other smaller diversions in the Delta and Central Valley rivers. Fish entrainment and subsequent mortality are highly variable among species and may be a function of the size of the diversion, the location of the diversion, the behavior of the fish (Swanson et al. 2004, 2005), and other factors, such as fish screens, the presence of predatory species, and water temperature. Diversions that divert relatively little water from the total channel and with low approach velocities are assumed to minimize stress and protect fish from entrainment.

Juvenile striped bass populations have steadily declined since the mid-1960s partially because of entrainment losses of eggs and young fish at water diversions (Foss and Miller 2001). The CVP and SWP fish facilities indicate entrainment of adult delta smelt during spawning migration from December through April (California Department of Water Resources and Bureau of Reclamation 1994). Juveniles are entrained primarily from April through June. Young-of-year splittail are entrained between April and August when fish are moving downstream into the estuary (Cech et al. 1979 as cited in Moyle 2002). Juvenile Chinook salmon are entrained in all months but primarily from November through June when juveniles are migrating downstream.

Although several studies documenting entrainment at small, unscreened Delta diversions are available, few address population-level effects or accurately estimate the total loss of fish at the

diversions studied (Moyle and Israel 2005). Some diversions may in fact entrain large numbers of individuals. However, many studies report capturing mostly larval or post-larval fish, with the majority of the catch being dominated by non-native species such as gobies, threadfin shad, and striped bass (Cook and Buffaloe 1998; Nobriga et al. 2004).

Contaminants

In the Sacramento and San Joaquin River basins, industrial and municipal discharge and agricultural runoff transport contaminants into rivers and streams that ultimately flow into the Delta. Principal pollutants in the Delta are agricultural chemicals and their derivatives (Herbold et al. 1992). Organophosphate insecticides, such as carbofuran, chlorpyrifos, and diazinon, are present throughout the Central Valley and dispersed in agricultural and urban runoff. The "first-flush" storm event or the "dormant spray" storm event is of most concern because of the higher concentration of contaminants in the runoff. In particular, diazinon and chlorpyrifos are applied to control wood-boring insects in dormant stone fruit orchards from December to February (Zamora et al. 2003). These contaminants enter rivers in winter runoff and enter the estuary in concentrations that can be toxic to invertebrates (CALFED Bay-Delta Program 2000). Unlike severe bioaccumulators such as organochlorine pesticides, organophosphate pesticides are typically metabolized by most invertebrates. However, some organophosphate pesticides do not bioaccumulate, and some do bioaccumulate. In particular, diazinon has a solubility of 68.9 milligrams per liter (mg/L) (at 68°F), but should not bioaccumulate in aquatic organisms (Zamora et al. 2003). Chlorpyrifos, on the other hand, is more persistent in the environment and tends to be hydrophobic to the water column. Chlorpyrifos has a lower solubility than diazinon (1.12 mg/L at 75°F) and has a significant potential to bioaccumulate in aquatic organisms (Zamora et al. 2003). Because some organophosphate may accumulate in living organisms, they may become toxic to fish species, especially those life stages that remain in the system year-round and spend considerable time there during the early stages of development, such as Chinook salmon, steelhead, splittail, green sturgeon, and delta smelt.

Mercury contamination from historical mining activities is extensive on both sides of the Central Valley and occurs primarily from widely scattered hydraulic mining debris along eastside tributaries and active abandoned mines and associated debris piles on the west side. These sources continue to deposit significant amounts of mercury into the Bay-Delta system. The Cosumnes River, Yolo Bypass, and Sacramento River are the primary ongoing sources of mercury contamination in the Bay-Delta. Mercury occurs in several forms, including pure elemental mercury and toxic methylmercury. Mercury is mobile in aquatic systems as aqueous mercury or when attached to suspended particulate matter. Methylmercury is a significant water quality concern because small amounts can bioaccumulate in fish to levels that are toxic to humans and wildlife. In the Delta, mercury concentrations in bluegill, Sacramento sucker, and largemouth bass have been found to exceed the human health standard of 0.5 part per million (ppm) by two to six times (Slotten 1991).

Other contaminants of particular concern in the Bay-Delta system include high concentrations of trace elements such as selenium, copper, cadmium, and chromium; however, their effects on higher trophic levels are poorly understood, in part as a result of the complex distribution of high concentrations in both time and space (Herbold et al. 1992). In general, it appears that the highest concentrations occur in areas where human activity adjacent to the bay is also the highest. Although these trace elements also occur naturally, concentrations of these trace elements have been found to be high enough to adversely affect the growth and reproduction of aquatic animals in laboratory experiments (Herbold et al. 1992).

Further discussion on water quality constituents of concern can be found in Section 3.3, Water Quality and Groundwater Resources.

Predation

Nonnative species cause substantial predation mortality on native species. Studies at Clifton Court Forebay estimated predator-related mortality of hatchery-reared fall-run Chinook salmon to be from about 60% to more than 95%. Although the predation contribution to mortality is uncertain, the estimated mortality suggests that striped bass and other predatory fish, primarily non-native, pose a threat to juvenile Chinook salmon moving downstream, especially where the stream channel has been altered from natural conditions. Turbulence from water passing over dams and other structures may disorient juvenile Chinook salmon and steelhead, increasing their vulnerability to predators. Predators such as striped bass, largemouth bass, and catfish also prey on delta smelt and splittail (U.S. Fish and Wildlife Service 1996).

Food

Food availability and type affect survival of fish species. Species such as threadfin shad and wakasagi may affect delta smelt survival through competition for food. Introduction of non-native food organisms also may have an effect on delta smelt and other species' survival. Non-native zooplankton species are more difficult for small smelt and striped bass to capture, increasing the likelihood of larval starvation (Moyle 2002). Splittail feed on opossum shrimp, which in turn feed on native copepods that have shown reduced abundance, potentially attributable to the introduction of non-native zooplankton and the Asiatic clam (*Potamorcorbula amurensis)*. In addition, flow affects the abundance of food in rivers, the Delta, and Suisun Bay. In general, higher flows result in higher productivity, including a higher input of nutrients from channel margins and floodplain inundation, and higher production when low salinity occurs in the shallows of Suisun Bay. Higher productivity increases the availability of prey organisms for delta smelt and other fish species.

3.9.3 Environmental Consequences

This section describes the effect analysis relating to fisheries for the proposed program. It describes the methods used to determine the effects of the program and lists the thresholds used to conclude whether an effect would be adverse or significant. How this effect differs among reaches is discussed, if applicable. Measures to mitigate (i.e., avoid, minimize, rectify, reduce, eliminate, or compensate for) adverse effects accompany each effect discussion.

3.9.3.1 Assessment Methods

3.9.3.1.1 Prefield Investigation

To prepare for the field surveys and analysis of the potential effects of the proposed program on fish species, fisheries biologists reviewed existing resource information related to the study area to evaluate whether sensitive habitats and special-status fish species are known from or could occur in the study area. The information reviewed included the following sources:

- a USFWS list of endangered, threatened, and proposed species for the Sacramento West, Clarksburg, Liberty Island, and Rio Vista USGS 7.5-minute quadrangle and Sacramento and Yolo Counties (U.S. Fish and Wildlife Service 2009); and
- published and unpublished documents and reports pertaining to the study area.

3.9.3.1.2 Field Surveys

A reconnaissance-level survey of the study area was conducted by an ICF International fisheries biologist on October 26, 2007. During the survey, fish habitat was identified and evaluated for its ability to support special-status fish species.

3.9.3.2 Determination of Effects

For this analysis, an effect pertaining to special-status fish species and their habitats was considered adverse under NEPA or significant under CEQA if it would result in any of the following environmental effects, which are based on professional practice and CEQA Guidelines Appendix G (14 CCR 15000 *et seq.).*

Assessment species are selected based on listing under the ESA and/or CESA. An effect was considered adverse under NEPA and significant under CEQA if program actions would substantially reduce the abundance and distribution of the identified important fish species. Additionally, adverse effects/significant impacts may occur if the program alternatives would result in:

- substantial interference with the movement of any resident or migratory fish species;
- substantial long- or short-term loss of habitat quality or quantity;
- substantial adverse effects on rare or endangered species, candidate species, other special-status species, or habitat of the species; or
- substantial adverse effects on fish communities or species protected by applicable environmental plans and goals.

3.9.3.2.1 Effect Assumptions

The determination of significance requires that:

- environmental conditions are measurably changed by the program,
- the change in environmental conditions adversely affects a species or its habitat,
- the change in environmental conditions is permanent or ongoing or affects a substantial proportion of the species population, or
- species population abundance is likely reduced, including a short-term reduction.

Qualitative relationships between environmental conditions and life stage survival are the basis of the effect assessment. Cause-and-effect relationships are identified for assessment species, including the relationship between environmental conditions and habitat and the effects of changes in habitat on survival. Determination of significance requires a qualitative or quantitative assessment of population sensitivity to changes in survival of specific life stages.

3.9.3.2.2 Effect Mechanisms

The assessment of effects considers the occurrence and potential occurrence of species and life stages relative to the magnitude, timing, frequency, and duration of program activities. Species habitat attributes potentially affected by construction activities include rearing habitat area and migration habitat conditions. Short-term effects on fish species attributable to bank protection activities include water quality effects and noise and disturbance. Long-term effects on fish habitat include loss of aquatic vegetation and SRA cover. This evaluation of effects on special-status fish species was based on the analysis of the proposed levee treatments.

Short-term construction effects are evaluated qualitatively based on general knowledge of the physiological tolerances and behavioral responses of listed fish species to potential increases in turbidity and suspended sediment, noise, and contaminants.

3.9.3.3 Effects and Mitigation Measures

3.9.3.3.1 No Action Alternative

The No Action Alternative is the continuation of the existing deficiencies along the nine levee reaches and absence of levee improvements to increase the level of protection. Current levee operations and maintenance activities would continue. No construction-related release of contaminants would occur, and no noise and disturbance to special-status fish species or construction-related loss of habitat for special-status fish species would occur. The current levee maintenance activities, including mowing and application of herbicides, would continue.

Without levee improvements, there is the continued risk of levee failure. Under these conditions, any of the deficiencies could cause portions of the levee system to fail, triggering widespread flooding and extensive damage. A catastrophic levee failure could result in the displacement of fish into flooded areas and the potential for stranding and mortality. In addition, adverse water quality effects could result from the release of hazardous materials during a flooding event, which could lead to stress and direct mortality or adversely affect migration, spawning and rearing habitat of fish species in the Sacramento River, Yolo Bypass, and the Delta. Emergency clean-up and earth-moving activities could also result in an increase in sediment and turbidity and the release of hazardous materials into the Sacramento River, the Delta and adjacent waterways that adversely affect migration, spawning or rearing habitat, or result in direct mortality of special status fish species. Depending on the magnitude of the flood, emergency clean-up activities could last for days, weeks, or even months. If a flood occurred in late winter, clean-up activities could last into the spring, a critical time for migration, movement and rearing of winter-run and spring-run Chinook salmon, steelhead, and green sturgeon. Given the unpredictable nature of emergency clean-up activities, is it likely that implementation of BMPs and measures to reduce effects on fish would not be possible. All of these effects would be considered significant. Furthermore, if levees along the Sacramento River were to collapse, important SRA habitat would be lost. Restoration of this critical habitat could require decades. All of these effects would be considered significant; however, given the uncertainty of the occurrence or magnitude of such an event, potential effects on fisheries cannot be quantified based on available information.

As discussed under the No Action Alternative in section 3.8, Vegetation and Wetlands, compliance with the vegetation-free zone as described in the USACE's Vegetation Guidance would be required with or without program implementation. Compliance with the vegetation guidance could result in

the removal of a substantial amount of vegetation, including riparian vegetation that supports SRA habitat. This would result in adverse impacts on fish and their habitats. However, given the uncertainties surrounding the potential for variances and implementation of the vegetation guidance, an estimation of effects is too speculative.

3.9.3.3.2 Flood and Recreation Program Alternatives

Effect FISH-1: Permanent Loss of Habitat, Including Shaded Riverine Aquatic Cover, for Special-Status Fish Species Resulting from Levee Vegetation Removal

All levee alternatives proposed under the WSLIP would follow USACE's policies regarding vegetation on levees, which forbid all woody vegetation on the crown, slopes, and within 15 feet of the waterside and landside levee toes. These zones would be maintained free of woody vegetation in perpetuity. Thus, the removal of a substantial amount of mature trees and vegetation from the banks of the Sacramento River may be required.

Permanent loss of the woody vegetation in compliance with USACE's policies would result in a substantial adverse effect on riparian habitat and potentially on SRA. The full extent of this effect is dependent on what portions of the existing levee would be officially deemed as the levee prism according to USACE. In some cases, the current levees are wider than the minimum requirements (or may become wider with the implementation of program alternatives such as an adjacent levee raise) and existing vegetation may fall outside of the vegetation- free zone. Moreover, dependent on site conditions, variances may be issued on a case-by-case basis that would allow vegetation to remain.

Because of the numerous ways that riparian vegetation influences the stream ecosystem, the effects of altering riparian vegetation are highly variable, ranging from increased sedimentation and warmer localized stream temperature to decreased food production and habitat complexity.

Removal of riparian vegetation would expose soils to erosive forces such as wind and rain, and could reduce overhead and instream cover (e.g., SRA cover). The removal of riparian vegetation, large woody debris, and aquatic vegetation directly affects the quantity and quality of cover for fish and aquatic invertebrates.

The loss of riparian vegetation that supports SRA cover as a result of vegetation removal and maintenance activities would result in greater fragmentation of existing SRA cover. Although some of the existing SRA cover currently is fragmented, further loss or fragmentation of SRA cover in the study area contributes to the increasing and cumulative degradation of the sensitive natural community in the Sacramento River. The study area reach of the Sacramento River is the only pathway for anadromous fish species to up-migrate from the Pacific Ocean (where they live their adult life stage) to upstream habitat where they spawn and rear, and conversely is the only out-migration pathway except in cases where individuals may use the Yolo Bypass as they are carried that way in high-water events. Loss of habitat in this reach would substantially impede the ability of anadromous fish (including special-status species) to complete their life cycle and reproduce.

Because of the unique value and relative scarcity of this cover type in the Sacramento and San Joaquin River systems, and because SRA cover is an essential component of fish habitat, removal of SRA cover would result in an adverse/significant effect on special-status fish such as juvenile Chinook salmon, steelhead, and Sacramento splittail. Implementation of Mitigation Measure FISH-MM-1 would reduce the effect on species in the area over time but because mature riparian habitat

cannot be replaced in the short term, this effect would still be an adverse effect on special-status fish species. In addition, dependent on the amount of the effect, implementation of Mitigation Measure FISH-MM-1 may reduce but not fully compensate for effects which would, therefore, be potentially adverse and unavoidable.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall ▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Closure structure ▪ Interior drain ▪ Jet grouting ▪ Relief wells	▪ Seepage berm ▪ Sheet pile wall ▪ Slurry cutoff wall ▪ Slope flattening ▪ Stability berm ▪ Rock slope protection ▪ Setback levee
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

Although different flood alternatives are proposed for the reaches, this effect would occur at the following reaches: Sacramento River North and South Levees, Port North and South Levees, Yolo Bypass Levee, and the Sacramento Bypass Levee. SRA cover occurs in the Sacramento River North Levee and Sacramento River South Levee reaches. Other reaches have little or no existing SRA.

Effect FISH-1 Finding	With Mitigation
Significant	Potentially significant and unavoidable

Mitigation

Mitigation Measure FISH-MM-1: Compensate for Unavoidable Effects on Shaded Riverine Aquatic Cover

WSAFCA will compensate for effects on SRA cover. WSAFCA will apply the USFWS Habitat Evaluation Procedure (HEP) and Standard Assessment Program (SAM) to compensate for SRA cover, which includes shallow water, natural substrates, inundated vegetation during spring and winter, overhanging shade, and instream structure. The objective of this plan will be to protect existing high-value SRA cover, minimize unavoidable losses of SRA cover, and fully compensate for these losses through a combination of on- and off-site planting of native riparian vegetation in the study area. This plan will be implemented prior to or concurrently with program implementation and will include measurable objectives and performance measures, monitoring methods, and remedial actions to ensure full compensation of SRA cover and riparian losses. Direct and indirect effects resulting in permanent losses of SRA cover will be calculated by the HEP and SAM and compensated for accordingly. Elements of the plan will include limiting the extent of bank and channel armor to

the minimum necessary to meet the flood-protection objectives, preserving large riparian trees and large woody debris, and incorporating native woody vegetation in the rock slope protection proposed for the bank and low-flow shoreline of the Sacramento River. In addition, the compensation plan will include measures to compensate for and enhance SRA cover and riparian vegetation in the area adjacent to the Sacramento River. Potential compensation and enhancement measures include removing existing concrete or rock armor and/or planting banks and adjacent floodplains in areas where low-quality SRA and riparian values currently exist. These measures are expected to compensate (to the degree allowable) for program effects on SRA cover and riparian habitat and minimize potential effects on listed species to negligible levels.

Effect FISH-2: Loss of Habitat for Special-Status Fish Species as a Result of Construction

Program actions would result in the construction-related loss of riparian habitat. As discussed above under Effect FISH-1, riparian vegetation that supports SRA cover directly influences the quality of fish habitat, affecting cover, food, in-stream habitat complexity, stream bank stability, and temperature regulation. Large woody debris usually originates from riparian trees and provides habitat complexity in aquatic environments, an essential component of fish habitat.

Removal of SRA cover is considered an adverse/significant effect because of the unique value and relative scarcity of this cover type in the Sacramento and San Joaquin River systems, and because SRA cover is an essential component of fish habitat, especially for salmonids.

Removal of riparian vegetation, SRA, nearshore aquatic habitat, and floodplain habitat during construction would result in adverse effects on special-status fish such as juvenile Chinook salmon, steelhead, and Sacramento splittail. This effect is considered adverse. As discussed above under FISH-1 regarding the limitations caused by the vegetation-free zone, and dependent on the amount of the effect, implementation of FISH-MM-1 may reduce but not fully compensate for effects. Effect FISH-2 may, therefore, be potentially adverse and unavoidable.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall	▪ Seepage berm
	▪ Levee raise (in place)	▪ Sheet pile wall
	▪ Levee raise (adjacent)	▪ Slurry cutoff wall
	▪ Levee raise (full)	▪ Slope flattening
	▪ Closure structure	▪ Stability berm
	▪ Interior drain	▪ Rock slope protection
	▪ Jet grouting	▪ Setback levee
	▪ Relief wells	▪ Vegetation removal
Recreation	▪ Trails	▪ Developed water access
	▪ Riverside parks	▪ Special projects

Affected Reaches

Although different flood alternatives are proposed for the reaches, this effect would occur primarily at the following reaches: Sacramento River North and South Levees, Port North and South Levee, Yolo Bypass Levee, and the Sacramento Bypass Levee. SRA cover occurs in the Sacramento River North Levee and Sacramento River South Levee reaches. Other reaches have little or no existing SRA.

Effect FISH-2 Finding	With Mitigation
Significant	Less than significant to potentially significant and unavoidable

Mitigation

Mitigation Measure FISH-MM-1: Compensate for Unavoidable Effects on Shaded Riverine Aquatic Cover

Effect FISH-3: Increase in Sedimentation and Turbidity in Adjacent Water Bodies as a Result of Construction

Program actions would require ground-disturbing activities that potentially cause erosion and soil disturbance, subsequently resulting in sediment transport and delivery to aquatic habitats. Increases in sedimentation and turbidity have been shown to affect fish physiology, behavior, and habitat. An increase in sedimentation and turbidity could occur in adjacent water bodies during earth-moving activities.

High concentrations of suspended sediment can have direct and indirect effects on fish. In general, larger fish tend to be more tolerant than smaller fish, while eggs and fry are the least tolerant. For salmonids, elevated turbidity levels have been observed to elicit several behavioral and physiological responses: gill flaring, coughing, avoidance, and increase in blood sugar levels. These responses indicate some levels of stress. Stress responses are generally higher with increasing turbidity and decreasing particle size. Turbidity may reach levels associated with avoidance behavior and reduced feeding success. Migrating adult salmonids have been reported to avoid high silt loads or cease migration when such loads are unavoidable (Cordon and Kelley 1961 in Bjornn and Reiser 1991).

Short-term increases in turbidity and suspended sediment may disrupt feeding activities or result in a temporary displacement of fish from preferred habitats. High concentrations of fine sediments reduce or eliminate much of the suitable substrate necessary for macroinvertebrate production, essentially limiting the food available to juvenile salmonids (Meehan 1991) and other species. Consequently, growth rates of fish could be reduced if suspended sediment and turbidity levels substantially exceed ambient levels for prolonged periods. In addition, substantial sediment input could adversely affect the migration of migratory species.

Disturbance of soil adjacent to the shoreline along levee toes and faces would temporarily increase turbidity above natural backgrounds in the immediate vicinity of these activities, potentially affecting fish species. It is expected that turbidity resulting from construction and maintenance activities would be intense in the vicinity of the activity but would rapidly attenuate with time and space.

The potential for adverse effects on fish from an increase in turbidity and sedimentation in adjacent waters is low for the following reasons.

- Environmental commitments, including an erosion and sediment control plan and SWPPP, would be developed and implemented before and during construction activities and would minimize the potential for increasing sedimentation and turbidity.
- Any increases in turbidity and sedimentation as a result of program activities would be temporary and limited to small portions of the overall water body.
- In-water construction would be limited to the typical construction season and during periods of low fish abundance, and outside the principal spawning and migration season. Typical construction season generally corresponds to the dry season, but WSLIP construction may occur outside the limits of the dry season, only as allowed by applicable permit conditions.
- Migratory and resident fish would likely move upstream, downstream, or laterally to an unaffected portion of the river in response to in-channel work and would therefore be unaffected by any increases in turbidity or sedimentation should they occur.
- If present, migratory species, such as adult and juvenile salmonids, would be expected to bypass channel reaches with elevated turbidity and sediment levels because a sufficient portion of the channel's width (i.e., zone of passage) would remain unaffected.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall ▪ Levee raise (in place) ▪ Levee raise (full) ▪ Closure structure ▪ Jet grouting ▪ Sheet pile wall	▪ Slurry cutoff wall ▪ Slope flattening ▪ Rock slope protection ▪ Setback levee ▪ Vegetation removal
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

Although different flood alternatives are proposed for the reaches, this effect would primarily occur at the following reaches: Sacramento River North and South Levees, Yolo Bypass Levee, Sacramento Bypass Levee. To a lesser extent this effect would occur in the Port North and South Levee reaches and the DWSC East and West Levees because the DWSC and Barge Canal do not typically support habitat for special status fish species, but do provide habitat for resident species.

Effect FISH-3 Finding	With Mitigation
Less than significant	N/A

Effect FISH-4: Release of Contaminants into Adjacent Water Bodies as a Result of Construction

Program actions may involve storage, use, or discharge of toxic and other harmful substances near the Sacramento River and other water bodies (or in areas that drain to these water bodies). Construction activities will involve the use of heavy equipment, cranes, compactors, and other construction equipment that use petroleum products (e.g., fuels, lubricants, hydraulic fluids, coolants). All of these materials may be toxic to fish and other aquatic organisms. An accidental spill or inadvertent discharge of these materials could affect the water quality of the river or water body and thereby affect fish or fish habitat.

Potential effects can range from avoidance of habitat in the vicinity of the construction activity to mortality, which could occur through exposure to lethal concentrations of contaminants or exposure to non-lethal levels that cause physiological stress and increased susceptibility to other sources of mortality (e.g., predation, disease).

Under the proposed program, accidental spills of construction materials such as concrete, fuels, oils, and coolants are not expected to occur. The program would adhere to environmental commitments to implement an SWPPP and an SPCCP, and a BSSCP, as described in Section 2.9 of Chapter 2, Alternatives, which would make any construction-related effects on water quality (and fish or fish habitat) not adverse/less than significant. If a spill were to occur, the SPCCP and Fran-Out Contingency Plan would be followed and Mitigation Measure WQ-MM-1, Implement Measures to Maintain Surface Water Quality and Groundwater Quality (as described in Section 3.3, Water Quality and Groundwater Resources), would be implemented to ensure water quality is returned to baseline conditions.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall	▪ Sheet pile wall
	▪ Levee raise (in place)	▪ Slurry cutoff wall
	▪ Levee raise (adjacent)	▪ Slope flattening
	▪ Levee raise (full)	▪ Rock slope protection
	▪ Closure structure	▪ Setback levee
	▪ Jet grouting	▪ Vegetation removal
Recreation	▪ Trails	▪ Developed water access
	▪ Riverside parks	▪ Special projects

Affected Reaches

Although different flood alternatives are proposed for the reaches, this effect would occur at the following reaches: Sacramento River North and South Levees, Port North and South Levee, Yolo Bypass Levee, Sacramento Bypass Levee, and the DWSC East and West Levees.

Effect FISH-4 Finding	With Mitigation
Less than significant	N/A

Effect FISH-5: Noise and Disturbance of Special-Status Fish Species as a Result of Construction

Construction-related short-term effects on fish would include effects related to noise, vibrations, artificial light, and other physical disturbances caused by heavy equipment operation. These types of physical disturbances can disrupt or delay normal activities, or cause injury or mortality. The potential magnitude of effects depends on a number of factors, including the type and intensity of the disturbance, proximity of the action to the water body, timing of actions relative to the occurrence of sensitive life stages, and frequency and duration of activities.

For most activities, if present, noise-related effects on fish would be limited to avoidance behavior in response to movements, noises, and shadows caused by construction personnel and equipment operating in or adjacent to the water body. However, construction-related noise levels are not expected to cause delay or adversely affect upstream or downstream migration of salmon, steelhead, and other migratory species for the reasons listed below.

- Construction would be limited to the typical construction season and during periods of low abundance, and outside the principal spawning and migration season. Typical construction season generally corresponds to the dry season, but WSLIP construction may occur outside the limits of the dry season, only as allowed by applicable permit conditions.
- Migratory and resident fish would likely move upstream, downstream, or laterally to an unaffected portion of the river in response noise or disturbance and would therefore be unaffected.
- If present, migratory species, such as adult and juvenile salmonids, would be expected to bypass channel reaches with noises or disturbances because a sufficient portion of the channel's width (i.e., zone of passage) would remain unaffected.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall	▪ Sheet pile wall
	▪ Levee raise (in place)	▪ Slurry cutoff wall
	▪ Levee raise (adjacent)	▪ Slope flattening
	▪ Levee raise (full)	▪ Rock slope protection
	▪ Closure structure	▪ Setback levee
	▪ Jet grouting	▪ Vegetation removal
Recreation	▪ Riverside parks	▪ Developed water access

Affected Reaches

Although different flood alternatives are proposed for the reaches, this effect would occur at the following reaches: Sacramento River North and South Levees, Port North and South Levee, Yolo Bypass Levee, Sacramento Bypass Levee, and the DWSC East and West Levees.

Effect FISH-5 Finding	With Mitigation
Less than significant	N/A

Effect FISH-6: Loss of Fish, Including Special-Status Species, from Direct Injury as a Result of Construction

Program construction elements would involve using heavy equipment and other techniques that could result in direct injury, including mortality, to fish in the study area. In-water construction associated with levee degradation and reconstruction could directly kill or injure fish through direct contact with construction equipment. Placement of materials such as rock slope protection could directly kill or injure fish present during time of rock placement. Resident fish that use nearshore habitats are the most likely to be affected because these species would be most abundant in these habitats during time of construction (summer and early fall). In contrast, sensitive native species such as juvenile salmonids would be less likely to be affected because these species typically occur in the study area only seasonally (fall, winter and spring); consequently, their relative abundances at the time of construction would be low.

The number of fish potentially injured during construction would likely be small because of the reasons listed below.

- In-water construction would be limited to periods of low abundance, and outside the principal spawning and migration season, of sensitive native species (e.g., salmonids).
- Most fish would move upstream, downstream, or laterally to avoid the affected portion of the river in response to in-channel work.
- In-water construction activity would occur over a relatively short period (i.e., one construction season per project).
- The aquatic habitat that would be directly affected by construction equipment and placement of any materials represents a small percentage of the total stream habitat available, thereby limits the number of fish potentially exposed to directly injury and mortality.

Direct injury or mortality associated with direct contact with construction equipment and placement of materials (rock slope protection) during construction would result in effects that are less than significant.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Levee raise (full) ▪ Setback levee	▪ Slope flattening ▪ Rock slope protection
Recreation	▪ Riverside parks	▪ Developed water access

Affected Reaches

Although different flood and recreation alternatives are proposed for the reaches, this effect would occur at the following reaches: Sacramento River North and South Levees, Port North and Port South Levees, and the DWSC East and West Levees.

Effect FISH-6 Finding	With Mitigation
Less than significant	N/A

Effect FISH-7: Increase in Sedimentation and Turbidity of Adjacent Water Bodies as a Result of Boating Activity

Boating activity associated with the new marinas may contribute to shoreline erosion and increase the concentration of suspended sediment and turbidity in the area, resulting in potential adverse effects on fish and other aquatic organisms. Wakes generated by passing boats can suspend fine sediments, increase turbidity, and disrupt the activities of juvenile fish in shallow waters along the shoreline. The effects of boat wakes and associated turbidity on listed fish species likely would be limited to behavioral effects.

Potential effects on listed fish species would be minimized by enforcing the existing No-Wake Zone, with its 5-mile-per-hour speed limit in the main river, and posting "no-wake" signs at the marinas and other high-visibility locations upstream and downstream of the marinas.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative
Recreation	▪ Developed water access ▪ Riverside parks

Affected Reaches

This effect would occur in the following reaches: Sacramento River North and South Levee reaches and the Port North and Port South Levee reaches. Each of these reaches includes riverside parks and developed water access. The Sacramento River North reach includes recreation elements proposed for the Washington Planning Area, Triangle Planning Area and Central Park (the Stone Lock Park component). The recreation elements for this reach include features such as marinas, docks, a water taxi, and floating restaurants. The Sacramento River South and Port North and South Levee reaches all encompass portions of the planned Central Park, which includes components such as a marina, improved boat ramps, and boat storage.

Effect FISH-7 Finding	With Mitigation
Less than significant	N/A

Effect FISH-8: Release of Contaminants to Adjacent Water Bodies as a Result of Boating Activity

Long-term operation of the marinas and the berthing of boats would increase the chance of spills or the leakage of gasoline, oil, and other contaminants into the Sacramento River. Operation and maintenance of the new marinas also would increase the amount of surface runoff from impervious surfaces (building roofs and parking areas), thereby increasing the potential for discharges of contaminants into the river.

Watercraft powered by carbureted and electronic injection two-stroke engines (manufactured before 1999) emits up to 25-30 percent of its fuel unburned into the water or atmosphere (California Department of Boating and Waterways 2010). Petroleum products have been shown to

be toxic to salmonids and other fish including lower organisms on the food chain such as the water flea *ceriodaphnia dubia* (National Marine Fisheries Service 2004). In general, the degree of toxicity depends on the concentration and duration of exposure. Direct effects of exposure to petroleum products include the physical coating of fish gills (reduction in oxygen uptake efficiency), disruption of the food absorption, and toxicological effects that can cause illness or death in fish. Indirect effects are less visible and may result in increased susceptibility to pathogens and parasites or adverse effects on prey organisms.

The construction of buildings, parking areas, roads, and walkways would increase impervious surfaces adjacent to the Sacramento River. These impervious surfaces would increase surface runoff by concentrating and redirecting stormwater during rain events and potentially increasing the concentrations of pollutants that enter the Sacramento River. These pollutants, which include heavy metals, hydrocarbons, nutrients, pesticides, polychlorinated biphenyls (PCBs), bromide, cyanide, sulphate, pathogenic bacteria, rubber, and sediment, threaten local water quality and can adversely affect the health of fish and other aquatic organisms.

The potential for adverse direct or indirect effects of toxic substances and other sources of pollution on listed fish species is generally low for small marinas as long as adequate measures are implemented to control runoff, prevent spills, and dispose of waste. Such measures include the SWPPP environmental commitment, which will help with construction-related erosion and the potential for chemicals to enter the waterway. Marinas and subject boaters would be required to follow environmental boating laws detailed by the California Coastal Commission. In addition, the California Clean Marina Program is an ongoing endeavor by a marina industry alliance, administered through the Marina Recreation Association, to provide environmentally clean facilities and protect the state's coastal and inland waters from pollution through compliance with management practices. Management practices include the following:

- petroleum containment;
- topside boat maintenance and cleaning;
- underwater boat hull cleaning;
- marina operations review and debris cleaning;
- boat sewage discharge containment;
- solid and liquid waste containment;
- fish waste containment;
- hazardous materials containment; and
- stormwater runoff control.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Recreation	▪ Developed water access	▪ Riverside parks

Affected Reaches

This effect would occur in the following reaches: Sacramento River North and South Levee reaches and the Port North and Port South Levee reaches. Each of these reaches includes riverside parks and developed water access. The Sacramento River North includes recreation elements proposed for the Washington Planning Area, Triangle Planning Area, and Central Park (the Stone Lock Park component). The recreation elements for this reach include features such as marinas, docks, a water taxi, and floating restaurants. The Sacramento River South and Port North and South Levee reaches all encompass portions of the planned Central Park, which includes components such as a marina, improved boat ramps, and boat storage.

Effect FISH-8 Finding	With Mitigation
Less than significant	N/A

Effect FISH-9: Disturbance of Special-Status Fish Species as a Result of Increased Boating Activity

Boating activity associated with the new marinas likely would increase ambient noise levels in the study area by a small, incremental amount. Little information is available to evaluate the effects of boating noise on fish. Exposure to boat engine noise has been found to cause temporary losses of hearing in the fathead minnow, according to a hearing specialist (Scholick and Yan 2002). The loss of hearing sensitivity may adversely affect the ability of fish to detect predators, locate prey, or sense their acoustic environment (Hastings and Popper 2005). Because ambient noise levels associated with recreational boat traffic generally fall within ranges that can affect fish behavior, increased boating activities associated with the new marinas may increase the frequency of disturbance or harassment of fish in the area. The potential for adverse behavioral effects is highest for juvenile fish that may respond in ways (e.g., leaving protective cover) that increase their vulnerability to predators.

Potential effects on listed fish species would be minimized by enforcing the existing No-Wake Zone, with its 5-mile-per-hour speed limit in the main river, and posting “no-wake” signs at the marinas and other high-visibility locations upstream and downstream of the marinas.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Recreation	▪ Developed water access	▪ Riverside parks

Affected Reaches

This effect would occur in the following reaches: Sacramento River North and South Levee reaches and the Port North and Port South Levee reaches. Each of these reaches includes riverside parks and developed water access. The Sacramento River North includes recreation elements proposed for the Washington Planning Area, Triangle Planning Area, and Central Park (the Stone Lock Park component). The recreation elements for this reach include features such as marinas, docks, a water

taxi, and floating restaurants. The Sacramento River South and Port North and South Levee reaches all encompass portions of the planned Central Park, which includes components such as a marina, improved boat ramps, and boat storage.

Effect FISH-9 Finding	With Mitigation
Less than significant	N/A

Effect FISH-10: Injury to or Mortality of Special-Status Fish Species as a Result of Pile Driving

Noise, vibrations, and other physical disturbances can harass fish, disrupt or delay normal activities, and cause injury or mortality. In fish, the hearing structures and swim bladder and surrounding tissues are particularly vulnerable to high-pressure sounds (Popper et al. 2006). The type and severity of effects depends on several factors, including the intensity and characteristics of the sound, the distance of the fish from the source, the timing of actions relative to the occurrence of sensitive life stages, and the frequency and duration of the noise-generating activities. The range of effects potentially includes behavioral effects, physiological stress, physical injury (including hearing loss), and mortality.

Given the proposed construction activities, the effects of noise on fish would be limited primarily to avoidance behavior in response to movements, vibrations, and noise caused by construction personnel and equipment operating in or adjacent to the Sacramento River. However, underwater pile-driving noise may reach levels that would be capable of injury or mortality of fish. Potential exposure of adult and juvenile salmonids to pile-driving sounds would be minimized by conducting all in-water pile-driving activities during a single construction season between July 1 and September 30 when the lowest numbers of Chinook salmon and steelhead are likely to be present in the area. Juvenile and adult green sturgeon may be present in the lower Sacramento River at this time.

There is no formal agreement on the thresholds that should be used to evaluate the potential for adverse behavioral effects from underwater pile-driving noise. NMFS and USFWS generally use 150 decibel (dB) root mean square as the threshold for behavioral effects for listed salmonids. Although no scientific support for this criterion is available, it is considered a general threshold for identifying potential behavioral responses (e.g., avoidance or alarm response) that could disrupt normal activity patterns or decrease the ability of fish to avoid predators.

Juvenile fish, including green sturgeon, that may be residing in the detection range of pile-driving sounds (approximately 1,100 yards) may respond in ways (e.g., leaving protective cover) that increase their vulnerability to predators.

The following measures are part of the proposed program and intended to reduce potential adverse effects on ESA-listed species and their habitat.

- All in-water construction activities will be limited to the period of June 1 through October 31 to avoid the primary migration periods of listed salmonids.
- In-water pile driving will be restricted to the period of July 1 through September 30 to avoid or minimize exposure of adults and juvenile salmonids to underwater pile-driving sounds.

- All pile driving will be conducted by a vibratory pile driver to minimize underwater sound levels during pile-driving operations.
- Pile driving will be conducted by barge to minimize disturbance of riparian habitat.
- Following construction, (where possible) native riparian vegetation will be planted on disturbed or exposed soils to control erosion and offset any losses of vegetation on the waterside slope of the levee

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Recreation	▪ Developed water access	▪ Riverside parks

Affected Reaches

This effect would occur in the following reaches: Sacramento River North and South Levee reaches and the Port North and Port South Levee reaches. Each of these reaches includes riverside parks and developed water access. The Sacramento River North includes recreation elements proposed for the Washington Planning Area, Triangle Planning Area, and Central Park (the Stone Lock Park component). The recreation elements for this reach include features such as marinas, docks, a water taxi, and floating restaurants. The Sacramento River South and Port North and South Levee reaches all encompass portions of the planned Central Park, which includes components such as a marina, improved boat ramps, and boat storage.

Effect FISH-10 Finding	With Mitigation
Less than significant	N/A

Effect FISH-11: Change in Predation on Native Fish Species Attributable to New Overwater and In-Water Structures

Overwater and in-water structures can alter underwater light conditions and provide potentially favorable holding conditions for adult fish, including species that prey on juvenile fishes. Permanent shading from the addition of floating docks and the permanent installation of piles and other structures in the Sacramento River could increase the number of predatory fish (e.g., striped bass, largemouth bass) holding in the study area and their ability to prey on juvenile salmonids and other fish.

The presence of floating docks, boats, and piles may result in localized increases in predation rates on juvenile salmon and steelhead relative to existing conditions. However, predation rates on juvenile salmon and steelhead at this location are likely low and will likely remain low under program conditions because most juveniles will continue to avoid the study area because of the lack of shallow-water habitat and suitable cover in the nearshore aquatic zone.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative
Recreation	• Developed water access

Affected Reaches

This effect would primarily occur within the Sacramento River North and South Levee reaches where developed water access components of the Recreation Program include construction of overwater and in-water structures such as marinas, docks, and floating restaurants. These recreation program alternatives could result in an increase in predation of native fish species such as juvenile salmonids. The Port North and South Levee reaches also include overwater and in-water structures within the Barge Canal; however, the likelihood of the presence of juvenile salmonids is limited because the passage is blocked from the mainstem of the Sacramento River by the barge locks. Therefore, the degree of this effect would be less in these reaches.

Effect FISH-11 Finding	With Mitigation
Less than significant	N/A

Effect FISH-12: Temporary Effects on Seasonal Floodplain Habitat for Special-Status Fish

Seasonal floodplain habitat may be adversely affected by program construction activities. Floodplain habitat is used by juvenile Chinook salmon for rearing and by Sacramento splittail for spawning and rearing. Studies (Sommer et al. 2001, 2005) conducted at the Yolo Bypass indicate that seasonal floodplain habitat provides substantially better rearing conditions than main channel habitat because of increased food production and reduced predation and competition from alien species (Jones & Stokes 2007). Green sturgeon and delta smelt may use floodplain habitat during migration. Effects on floodplain habitat would be temporary and primarily related to construction activities. Post-construction, any disturbed areas would be hydroseeded to provide reestablishment of wetland vegetation. Direct effects on fish would not be adverse because construction would be limited to the typical construction season and outside the principal spawning and migration season. Typical construction season generally corresponds to the dry season, but WSLIP construction may occur outside the limits of the dry season, only as allowed by applicable permit conditions.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Sheet pile wall ▪ Slurry cutoff wall	▪ Slope flattening ▪ Closure structure

Affected Reaches

This effect would occur in the Yolo Bypass and the Sacramento Bypass reaches.

Effect FISH-12 Finding	With Mitigation
Less than significant	N/A

Section 3.10
Wildlife

3.10.1 Introduction

This section describes the regulatory and environmental setting for wildlife resources, effects on wildlife resources that would result from the proposed program, and the mitigation measures that would reduce these effects.

The key sources of data and information used in the preparation of this section are listed and briefly described below.

- CNDDB records search of the Sacramento West, Clarksburg, Liberty Island, and Rio Vista USGS 7.5-minute quadrangles and the nine quads surrounding each (California Natural Diversity Database 2009)
- USFWS list of endangered, threatened, and proposed species for the Sacramento West, Clarksburg, Saxon, Liberty Island, and Rio Vista USGS 7.5-minute quadrangle and Sacramento, Yolo, and Solano Counties (U.S. Fish and Wildlife Service 2009)
- Vegetation data from the Yolo Natural Heritage Program (Yolo Natural Heritage Program 2009)
- Aerial photographs of the program study area
- *City of West Sacramento General Plan 2004* (City of West Sacramento 2004)
- *Yolo County General Plan* (Yolo County 2002)
- *Solano County General Plan* (Solano County 2008)
- Published and unpublished reports
- ICF International file information

An ICF International biologist conducted prefield investigations and reconnaissance-level field surveys in the study area, as described in the Environmental Consequences section below. This information was used to develop lists of special-status wildlife species that could be present in the study area. Special-status species with potential to occur in the study area are discussed in the Environmental Setting section.

3.10.2 Affected Environment

3.10.2.1 Regulatory Setting

3.10.2.1.1 Federal

Federal Endangered Species Act

The Federal ESA of 1973 and subsequent amendments provide for the conservation of listed endangered or threatened species or candidates for listing and the ecosystems on which they

depend. USFWS has jurisdiction over federally listed plants, wildlife, and resident fish and NMFS has jurisdiction over anadromous fish and marine fish and mammals.

Section 7: ESA Authorization Process for Federal Actions

Section 7 of the ESA provides a means for authorizing take of threatened and endangered species by Federal agencies. It applies to actions that are conducted, permitted, or funded by a Federal agency. Under ESA Section 7, the lead Federal agency conducting, funding, or permitting an action must consult with USFWS or NMFS, as appropriate, to ensure that the proposed action will not jeopardize the continued existence of an endangered or threatened species or destroy or adversely modify designated critical habitat. If a proposed action may affect a listed species or designated critical habitat, the lead agency is required to prepare a biological assessment (BA) evaluating the nature and severity of the expected effect. In response, USFWS or NMFS issues a biological opinion (BO), with a determination that the proposed action either:

- may jeopardize the continued existence of one or more listed species (jeopardy finding) or result in the destruction or adverse modification of critical habitat (adverse modification finding), or
- will not jeopardize the continued existence of any listed species (no jeopardy finding) or result in adverse modification of critical habitat (no adverse modification finding).

The BO issued by USFWS or NMFS may stipulate discretionary "reasonable and prudent" conservation measures. If it is determined the proposed program would not jeopardize the continued existence of a listed species, USFWS or NMFS would issue an incidental take statement to authorize the proposed activity.

Section 9: ESA Prohibitions

Section 9 of ESA prohibits the take of any fish or wildlife species listed under ESA as endangered. *Take*, as defined by ESA, means "to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in any such conduct." Harm is defined as "any act that kills or injures the species, including significant habitat modification." Take of threatened species also is prohibited under Section 9 unless otherwise authorized by Federal regulations.[1] Additionally, Section 9 prohibits removing, cutting, and maliciously damaging or destroying federally listed plants on sites under Federal jurisdiction.

Migratory Bird Treaty Act

The Migratory Bird Treaty Act (MBTA) (16 USC 703) enacts the provisions of treaties between the United States, Great Britain, Mexico, Japan, and the Soviet Union and authorizes the U.S. Secretary of the Interior to protect and regulate the taking of migratory birds. It establishes hunting seasons and capture limits for game species and protects migratory birds, their occupied nests, and their eggs (16 USC 703, 50 CFR 21, 50 CFR 10).

Executive Order 13186 (January 10, 2001) directs each Federal agency taking actions that have or may have a negative effect on migratory bird populations to work with USFWS to develop a

[1] In some cases, exceptions may be made for threatened species under ESA Section 4[d]; in such cases, USFWS or NMFS issues a "4[d] rule" describing protections for the threatened species and specifying the circumstances under which take is allowed.

memorandum of understanding (MOU) that will promote the conservation of migratory bird populations. Protocols developed under the MOU must include the following agency responsibilities:

- avoid and minimize, to the extent practicable, adverse effects on migratory bird resources when conducting agency actions;
- restore and enhance migratory bird habitats, as practicable; and
- prevent or abate the pollution or detrimental alteration of the environment for the benefit of migratory birds, as practicable.

The executive order is designed to assist Federal agencies in their efforts to comply with the MBTA, and does not constitute any legal authorization to take migratory birds.

Fish and Wildlife Coordination Act

The Fish and Wildlife Coordination Act, as amended in1946, requires consultation with USFWS and the state fish and wildlife agencies where the waters of any stream or other body of water are proposed, authorized, permitted, or licensed to be impounded, diverted, or otherwise controlled or modified under a Federal permit or license. Consultation is undertaken for the purpose of preventing loss of and damage to wildlife resources.

3.10.2.1.2 State

California Endangered Species Act

California implemented the CESA in 1984. The act prohibits the take of listed endangered and threatened species. Section 2090 of CESA requires state agencies to comply with endangered species protection and recovery and to promote conservation of these species. DFG administers the act and authorizes take through Section 2081 agreements (except for species designated as fully protected).

California Fish and Game Code

Section 1602 of the California Fish and Game Code (CFGC) requires project proponents to notify DFG before any project that would divert, obstruct, or change the natural flow, bed, channel, or bank of any river, stream, or lake. Preliminary notification and project review generally occur during the environmental process. When an existing fish or wildlife resource may be substantially adversely affected, DFG is required to propose reasonable changes to the project to protect the resources. These modifications are formalized in a streambed alteration agreement that becomes part of the plans, specifications, and bid documents for the project.

The CFGC provides protection from take for a variety of species, referred to as fully protected species. CFGC 5050 lists protected amphibians and reptiles. CFGC 5515 prohibits take of fully protected fish species. CFGC 3511 prohibits take of fully protected bird species. Fully protected mammals are protected under CFGC 4700. The CFGC defines take as "hunt, pursue, catch, capture, or kill, or attempt to hunt, pursue, catch, capture, or kill." Except for take related to scientific research, all take of fully protected species is prohibited.

CFGC 3503 prohibits the killing of birds or the destruction of bird nests. CFGC 3503.5 prohibits the killing of raptor species and destruction of raptor nests. Many bird species could potentially nest in the study area or vicinity. These nests would be protected under these sections of the CFGC.

3.10.2.1.3 Local

City of West Sacramento General Plan

In 1990, the City adopted the *City of West Sacramento General Plan*. The general plan was last revised and adopted in December 8, 2004. The general plan outlines goals and policies related to natural resources within the study area. The following objectives, policies, and implementation procedures are relevant to the study area:

Objective: To protect native vegetation and wildlife communities and habitat in West Sacramento

Policies

1. The City shall encourage and support development projects and programs that enhance public appreciation and awareness of the natural environment.
2. The City shall support state and federal policies for preservation and enhancement of riparian and wetland habitats by incorporating, as deemed appropriate, the findings and recommendations of *Sacramento Greenway Plan*, DFG, and USFWS into site-specific development proposals.
3. The City shall require site-specific surveys to identify significant wildlife habitat and vegetation resources for development projects locate in or near riparian or wetland areas.
4. The City shall support mitigation measures which provide for no net loss of riparian or wetland habitat acreage and value by regulating development in and near these habitats and promoting projects that avoid sensitive areas. Where habitat loss is unavoidable, the City shall seek replacement on at least a 1:1 basis. Replacement entails creating habitat that is similar in extent and ecological value to that displaced by the project. The replacement habitat should consist of locally occurring, native species and shall be located as close as possible to the project site or be part of a larger replacement habitat project.
5. To minimize disturbance to wildlife, the City shall require the provisions and maintenance of an adequate setback between significant wetland habitat and adjacent development. The buffer shall be landscaped with native or compatible introduced ornamental vegetation and may be used for passive recreation purposes.
6. The City shall encourage the maintenance of marsh and riparian vegetation along irrigation/drainage canals and along the Deep Water Ship Channel by encouraging that routine maintenance and clearing disturb only one bank per year and maintain the fringes of marsh vegetation.
7. The City shall seek to minimize the loss and degradation of wetland and riparian habitats at the following sites: Lake Washington and associated wetlands; Bee Lakes and associated riparian woodlands; riparian woodlands along the Sacramento River north of the I Street Bridge and south of the barge canal; and riparian woodlands along the Deep Water Ship Channel and the Yolo Bypass.
8. The City shall seek a cooperative effort with other jurisdictions; the State, and the federal government to conserve habitat. The goal of this effort shall be to preserve and enhance habitat values in appropriate large areas while allowing the orderly development within the incorporated areas of Yolo County. In the event a multi-jurisdictional effort is unsuccessful, the City shall adopt a conservation ordinance or plan that identifies specific habitats and sites where

development could diminish or eliminate significant biological habitat and protects them from the adverse effects of excavating, grading, filling, dredging, removing vegetation, landscaping with exotic species, and other incompatible uses and activities. In event protection is not possible, full mitigation shall be required.

9. The City shall seek to preserve populations of rare, threatened, and endangered wildlife or plant species.
10. The City shall not approve project that would cause unmitigatible impacts on rare, threatened, or endangered wildlife or plant species.
11. The City shall implement measures to ensure that development in the city does not adversely affect fishery resources in the Sacramento River, Deep Water Ship Channel, and Lake Washington.
12. Public access and recreation facilities shall not eliminate or degrade riparian habitat values. Trails, picnic areas, and other developments shall be sited to minimize impacts on sensitive wildlife habitat or riparian vegetation.
13. The City shall promote the use of native plants, especially valley oaks, for landscaping roadsides, parks, and private properties. In particular, native plants shall be used along the Sacramento River and in areas adjacent to riparian and wetland habitats.

Yolo County General Plan

The *Yolo County General Plan* was adopted in 1983. The objective of the general plan is to provide guidance for the development of Yolo County. The general plan promotes the preservation of farm land and open spaces to minimize the area of urbanization. The Open Space and Recreation Element of the general plan was updated in 2002. The following goals, objectives, and policies are relevant to wildlife resources in the study area:

Goals and Supporting Objectives

- OG-1: Preserve open space lands utilizing a variety of land use controls and regulations.
    - OO-1: Creation and maintenance of regulatory framework that places a high priority on preservation of public and private open space lands.
- OG-2: Preserve agricultural land as the principal component of the local open space program.
    - OO-2: Maintenance of Urban Boundaries to direct urban growth into existing towns and cities to protect open space and agricultural lands.
- OG-3: Ensure a harmonious relationship between open space users and agriculture.
    - OO-3: Avoidance of conflicts with agricultural activities.
    - OO-4: Clearly demarcated boundaries between public open space and private agricultural lands.
- OG-4: Protect and manage local water resources.
    - OO-5: Provision for open space corridors within existing and future development.
- OG-5: Preserve and enhance existing biological resources.
    - OO-6: No net loss of wetland and/or riparian habitat.

- OO-7: Maintenance of unique or sensitive plant or animal habitat.

- OG-8: Create a continuous open space corridor along Lower Cache Creek and provide expanded public access to the Yolo Bypass, Lower Putah Creek, Willow Slough, the Sacramento River, and the Blue Ridge Mountains.
  - OO-10: Development of partnerships with local stakeholder watershed organizations to expand existing public open space along Cache Creek, Lower Putah Creek, the Sacramento River and within the Yolo Bypass.

Policies

- **OP-4:** The County shall encourage and support coordinated efforts by State and federal agencies, cities, special districts, and non-profit and conservation organizations to protect lands containing open space resources.
- **OP-5:** The County shall utilize the CEQA process to identify significant impacts to open space and shall require new development to implement county-implemented mitigation measures that minimize such impacts.
- **OP-7:** Development shall be directed away from naturally occurring riparian areas and wetlands.
- **OP-8:** Open space buffers shall be utilized to separate incompatible uses from areas of unique biological or agricultural importance.
- **OP-18:** The County, in conjunction with cities in Yolo County, shall endeavor to adopt a Natural Communities Conservation Plan that protects wildlife resources, open space, and agricultural production.

Solano County General Plan

The *Solano County General Plan* was adopted by the Board of Supervisors on August 5, 2008. The general plan contains a resources element that strives to ensure conservation, preservation, and enhancement of natural, cultural, and open space resources to ensure a high quality of life for current and future county residents. The resources chapter of the general plan identifies the following goals, policies, and implementation measures associated with natural (biological) resources that will be used by Solano County in day-to-day decision making to protect these resources.

General Resource Goals

The goals and accompanying policies describe outcomes consistent with the following strategic directions of the general plan:

- preserving of the county's valued natural, cultural, and scenic resources;
- enhancing and restoring the natural environment and the county's diverse landscapes; and
- ensuring sustainable provision of energy, water, and mineral resources.

General Resource Policies

- **RS.G-1:** Manage and preserve the diverse land, water, and air resources of the county for the use and enrichment of the lives of present and future generations.

- **RS.G-2:** Ensure continued presence and viability of the county's various natural resources.
- **RS.G-3:** Repair environmental degradation that has occurred, and seek an optimum balance between the economic and social benefits of the county's natural resources.
- **RS.G-4:** Preserve, conserve, and enhance valuable open space lands that provide wildlife habitat; conserve natural and visual resources; convey cultural identity; and improve public safety.
- **RS.G-5:** Ensure availability of affordable energy supplies and require efficiency and conservation measures to minimize energy consumption.
- **RS.G-6:** Preserve the visual character and identity of communities by maintaining open space areas between them.
- **RS.G-7:** Ensure provision of an adequate, competitively priced and sustainable water supply and associated infrastructure to serve the needs of existing and future water users.
- **RS.G-8:** Achieve ongoing coordination between land use and water supply planning.
- **RS.G-9:** Protect, monitor, restore and enhance the quality of surface and groundwater resources to meet the needs of all beneficial uses.
- **RS.G-10:** Foster sound management of the land and water resources in Solano County's watersheds to minimize erosion and protect water quality using best management practices and protect downstream waterways and wetlands.

Biological Resource Policies

- **RS.P-1:** Protect and enhance the county's natural habitats and diverse plant and animal communities, particularly occurrences of special-status species, wetlands, sensitive natural communities, and habitat connections.
- **RS.P-2:** Manage the habitat found in natural areas and ensure its ecological health and ability to sustain diverse flora and fauna.
- **RS.P-3:** Focus conservation and protection efforts on high-priority habitat areas.
- **RS.P-4:** Together with property owners and federal and state agencies, identify feasible and economically viable methods of protecting and enhancing natural habitats and biological resources.
- **RS.P-5:** Protect and enhance wildlife movement corridors to ensure the health and long-term survival of local animal and plant populations. Preserve contiguous habitat areas to increase habitat value and to lower land management costs.
- **RS.P-6:** Protect oak woodlands and heritage trees and encourage the planting of native tree species in new developments and along road rights-of-way.

3.10.2.2 Environmental Setting

This section discusses the existing conditions related to wildlife resources in the study area.

3.10.2.2.1 Study Area

For the purposes of this program-level analysis, the study area for wildlife consists of the levees listed below plus an approximate 500-foot-wide landside buffer. The study area occurs in West Sacramento within the counties of Yolo and Solano.

The study area occurs along the reaches of the following levees:

- Sacramento Bypass Levee
- Sacramento River North Levee
- Yolo Bypass Levee
- Port North Levee
- Port South Levee
- DWSC West Levee
- DWSC East Levee
- Sacramento River South Levee
- South Cross Levee

The approximate elevations in the study area range from 10 to 35 feet above mean sea level.

3.10.2.2.2 Prefield Investigation

To prepare for the field surveys and analysis of the potential effects of the proposed program on wildlife species, wildlife biologists reviewed existing resource information related to the study area to evaluate whether sensitive habitats and special-status wildlife species are known from or could occur in the study area. The information reviewed included the following sources:

- a CNDDB records search of the Sacramento West, Clarksburg, Liberty Island, and Rio Vista USGS 7.5-minute quadrangles and the nine quads surrounding each (California Natural Diversity Database 2009);
- a USFWS list of endangered, threatened, and proposed species for the Sacramento West, Clarksburg, Liberty Island, and Rio Vista USGS 7.5-minute quadrangle and Sacramento and Yolo Counties (U.S. Fish and Wildlife Service 2009); and
- published and unpublished documents and reports pertaining to the study area.

3.10.2.2.3 Field Surveys

A reconnaissance-level survey of the study area was conducted by ICF International wildlife biologists on November 29, 2007, and on December 18 and 19, 2008; and January 9, 2009. During all surveys, wildlife habitat uses associated with land cover types were identified and habitats were evaluated for their ability to support special-status wildlife species.

A list of wildlife species observed in the study area is provided in Table 3.10-1.

Table 3.10-1. Wildlife Species Observed in the Study Area

Common Name	Scientific Name
Birds	
Acorn woodpecker	*Melanerpes formicivorus*
American coot	*Fulica americana*
American crow	*Corvus brachyrhynchos*
American goldfinch	*Carduelis tristis*
American kestrel	*Falco sparverius*
American white pelican	*Pelecanus erythrorhynchos*
Belted kingfisher	*Megaceryle alcyon*
Black-crowned night heron	*Nycticorax nycticorax*
Black phoebe	*Sayornis nigricans*
Brewer's blackbird	*Euphagus cyanocephalus*
Bufflehead	*Bucephala albeola*
Bushtit	*Psaltriparus minimus*
California towhee	*Pipilo crissalis*
Canada goose	*Branta canadensis*
Dark-eyed junco	*Junco hyemalis*
Double-crested cormorant	*Phalacrocorax auritus*
Eared grebe	*Podiceps nigricollis*
European starling	*Sturnus vulgaris*
Golden-crowned sparrow	*Zonotrichia atricapilla*
Great blue heron	*Ardea herodias*
Great egret	*Ardea alba*
Green heron	*Butorides virescens*
Gull sp.	*Larus* sp.
House wren	*Troglodytes aedon*
Killdeer	*Charadrius vociferus*
Mallard	*Anas platyrhynchos*
Mourning dove	*Zenaida macroura*
Northern flicker	*Colaptes auratus*
Northern harrier	*Circus cyaneus*
Red-tailed hawk	*Buteo jamaicensis*
Red-shoulder hawk	*Buteo lineatus*
Red-winged blackbird	*Agelaius phoeniceus*
Rock dove	*Columba livia*
Ruddy duck	*Oxyura jamaicensis*
Say's phoebe	*Sayornis saya*
Snowy egret	*Egretta thula*
Spotted towhee	*Pipilo erythrophthalmus*
Turkey vulture	*Cathartes aura*
Western meadow lark	*Sturnella neglecta*
Western scrub jay	*Aphelocoma californica*

Common Name	Scientific Name
White-crowned sparrow	*Zonotrichia leucophrys*
White-tailed kite	*Elanus leucurus*
Yellow-billed magpie	*Pica nuttalli*
Yellow-rumped warbler	*Dendroica coronata*
Mammals	
Black-tailed jack rabbit	*Lepus californicus*

3.10.2.2.4 Wildlife Habitat—Land Cover Type Associations

According to Yolo County overview vegetation map data (Yolo Natural Heritage Program 2009), the following land cover types occur in the study area: perennial aquatic (open water), emergent wetland, valley foothill riparian, woodlands and forest, grasslands and prairies, agricultural lands, and unvegetated, vacant, or developed lands. Each of the seven land cover types is discussed below and shown in Figure 3.8-1, in Section 3.8, Vegetation and Wetlands. These land cover types include jurisdictional wetlands and other waters of the United States and sensitive natural communities (foothill riparian forest and emergent wetland). The artificial land cover types consist of agricultural lands and developed lands.

This section summarizes the land cover types identified in the study area, describes the relationship between land cover types and wildlife habitats, and identifies common and special-status wildlife species associated with each habitat type. Although land cover types emphasize floristic composition, structure, and other physical attributes, each land cover type provides a specific function and value for wildlife species. In some instances, two or more land cover types may provide similar functions and values for wildlife (e.g., valley foothill riparian and woodlands and forest).

Perennial Aquatic

Within the study area, open water areas occur in the Sacramento River, DWSC, permanent ponds, and irrigation canals. Open water provides breeding, foraging, and migration habitat for numerous wildlife species. Mammal species commonly known to use perennial aquatic open water habitats include river otter (*Lontra canadensis*), which uses these areas for foraging and escape cover, and muskrat (*Ondatra zibethicus*), which may use deepwater areas as migration corridors between suitable foraging areas. Open water areas also provide essential foraging habitat for wading birds including great blue heron (*Ardea herodias*), great egret (*Ardea alba*), and snowy egret (*Egretta thula*); numerous waterfowl species including mallard (*Anas platyrhynchos*), ruddy duck (*Oxyura jamaicensis*), and bufflehead (*Bucephala albeola*); other water birds including eared grebe (*Podiceps nigricollis*), double-crested cormorants (*Phalacrocorax auritus*), and American white pelicans (*Pelecanus erythrorhynchos*); and land birds including black phoebe (*Sayornis nigricans*) and belted kingfisher (*Megaceryle alcyon*). These areas also provide rearing habitat, escape cover, and foraging habitat for reptiles and amphibians including western pond turtle (*Actinemys marmorata*), common garter snake (*Thamnophis sirtalis*), giant garter snake (*Thamnophis gigas*), bullfrog (*Rana catesbeiana*), Pacific tree frog (*Hyla regilla*), and western toad (*Bufo boreas*). The vegetated areas below the OHWM provide nesting habitat for numerous songbirds, including red-winged blackbird (*Agelaius phoeniceus*) and marsh wren (*Cistothorus palustris*), and wading birds such as Virginia rail (*Rallus limicola*).

Emergent Wetland

Although emergent wetland does not occur in large continuous patches within the study area, this habitat type is designated as a sensitive natural community by DFG and provides important wildlife habitat value. This land cover type provides nesting and foraging habitat for several songbirds, including red-winged blackbird, tricolored blackbird (*Agelaius tricolor*), and marsh wren; foraging and nesting habitat for northern harrier (*Circus cyaneus*) and Virginia rail; foraging and cover habitat for the reptiles and amphibians mentioned above; and potential nesting habitat for western pond turtle.

Valley Foothill Riparian

Riparian habitats are considered to be among the most productive wildlife habitats in California and typically support the most diverse wildlife habitats. In addition to providing important nesting and foraging habitat, riparian habitats function as wildlife movement corridors. Riparian habitat is designated by DFG as sensitive natural and provides high value to wildlife.

Riparian forest habitat along the Sacramento River has a dominant overstory of valley oak (*Quercus lobata*) with Fremont cottonwood (*Populus freemontii*), California sycamore (*Platanus racemosa*, and various willow species (*Salix* sp.). Depending on the location, the understory may consist of dense shrubs including blue elderberry (*Sambucus mexicana*) and Himalayan blackberry (*Rubus discolor*), or grass-dominated vegetation.

Overstory trees may be used for nesting and roosting by numerous raptors, including Swainson's hawk (*Buteo swainsoni*), white-tailed kite (*Elanus leucurus*), red-tailed hawk (*Buteo jamaicensis*), red-shouldered hawk (*Buteo lineatus*), great horned owl (*Bubo virginianus*), Cooper's hawk (*Accipiter cooperii*), and American kestrel (*Falco sparverius*) and the herons and egrets mentioned as foraging in open water areas. Overstory trees also provide suitable habitat for song birds such as Bullock's oriole (*Icterus bullockii*), yellow-rumped warbler (*Dendroica coronata*), tree swallow (*Tachycineta bicolor*), and western scrub jay (*Aphelocoma californica*). Riparian forest also provides important foraging habitat for resident, migratory, and wintering songbirds. The understory of riparian woodlands provide habitat for mammals, including various species rodents, raccoon (*Procyon lotor*), Virginia opossum (*Didelphis virginiana*), and striped skunk (*Mephitis mephitis*). Areas containing large, dense shrubby vegetation dominated by willow or blackberry may support tricolored blackbird. Riparian forests also provide cover and foraging habitat for reptiles and amphibians, such as terrestrial garter snake (*Thamnophis elegans*), gopher snake (*Pituophis catenifer*), Pacific tree frog, and western toad. Suitable areas in the understory may also be used as nesting habitat for western pond turtles.

Woodlands and Forest

Small patches of woodland and forest occur in the study area along the Sacramento River outside of the riparian forest areas. These areas are dominated by valley oak and provide similar wildlife habitat uses as the valley foothill riparian forest. Wildlife species that use valley foothill riparian forest typically use woodlands and forest areas. Additionally, yellow-billed magpie (*Pica nuttalli*), acorn woodpecker (*Melanerpes formicivorus*), and northern flicker (*Colaptes auratus*) nest and forage in these habitats. Reptiles including gopher snake (*Pituophis catenifer*) and California king snake (*Lampropeltis getulus californiae*) also frequent these habitats.

Grasslands and Prairies

Areas mapped as grasslands and prairies in the study area are dominated by non-native annual grasses, non-native ruderal vegetation, and may support stands of noxious weeds. Grassland generally occurs in disturbed areas, such as levee faces and edges of agricultural fields and roads; the species in this land cover type are generally weedy to invasive. The largest area of non-native annual grassland occurs near the DWSC East and West and Port South Levees, but grasslands are generally scattered throughout the study area.

Annual grasslands provide nesting and foraging habitat for several species of songbirds, including savanna sparrow (*Passerculus sandwichensis*), white-crowned sparrow (*Zonotrichia leucophrys*), and western meadowlark (*Sturnella neglecta*); and foraging habitat for several species of raptors including red-tailed hawk, white-tailed kite, northern harrier, great-horned owl, and Swainson's hawk. California ground squirrels commonly occur in annual grassland habitat. Their burrows provide important nesting habitat for western burrowing owls (*Athene cunicularia hypugea*). Reptiles found in these habitats include California kingsnake, gopher snake, and western rattlesnake (*Crotalus viridis*). Additionally, annual grassland areas surrounding levees and those adjacent to aquatic habitat may also provide potential winter hibercula for giant garter snake.

Agricultural Lands

Within the study area, agricultural lands include pasture, grain and hay fields, deciduous orchard (i.e., nuts, fruits), irrigated hay field, and irrigated row and field crops. General farming practices result in monotypic stands of vegetation for the growing season and bare ground in the fall and winter. Irrigation ditches are a part of most of the agricultural fields in the study area. Because the habitat provided by irrigation ditches is different from that of agricultural fields, it is discussed under the open water areas section above.

Agricultural lands provide foraging habitat for many wildlife species that occur in the study area. The value of agricultural lands for wildlife species depends on the crop type and typically varies by season and year, depending on the crop cycle and on the vegetative cover present at the site.

Row and field agricultural lands can provide high value foraging habitat for numerous resident and wintering raptors (particularly Swainson's hawk), songbirds, shorebirds, and wading birds. Agricultural lands also provide foraging habitat for rodents including deer mouse (*Peromyscus maniculatus*) and California meadow vole (*Microtus californicus*); other mammals including coyote (*Canis latrans*), raccoon, Virginia opossum; and reptiles including gopher snake and terrestrial garter snake.

Orchard crops typically provide less value to wildlife but may be used for nesting or foraging by American crow (*Corvus brachyrhynchos*), yellow-billed magpie, Brewer's blackbird (*Euphagus cyanocephalus*), brown-headed cowbird (*Molothrus ater*), European starling (*Sturnus vulgaris*), mourning dove (*Zenaida macroura*), and rock dove (*Columba livia*).

Developed Lands

Developed lands mapped in the study area include areas within levee roads, railways, roads, buildings, and landscapes as well as barren areas that have been disturbed and are not vegetated. A minimal amount of this cover type occurs in the study area. Because of the disturbance related to

installation of landscaping and the ongoing maintenance, these areas provide minimal value to wildlife.

3.10.2.2.5 Special-Status Wildlife Species

Special-status wildlife species are defined as animals that are legally protected under the ESA, CESA, or other regulations, and species that are considered sufficiently rare by the scientific community to qualify for such listing. Special-status species are defined as:

- species that are listed or proposed for listing as threatened or endangered under the ESA (50 CFR 17.12 for listed plants, 50 CFR 17.11 for listed animals, and various notices in the *Federal Register* for proposed species);
- species that are candidates for future listing as threatened or endangered under the ESA (72 FR 69034, December 6, 2007);
- species listed or proposed for listing by the State of California as threatened or endangered under the CESA (14 CCR 670.5);
- species that meet the definitions of rare or endangered under CEQA (State CEQA Guidelines Section 15380);
- animals that are California species of special concern (California Department of Fish and Game 2008; Remsen 1978; California Department of Fish and Game and Point Reyes Bird Observatory 2001 [birds]; Williams 1986 [mammals]; and Jennings and Hayes 1994 [amphibians and reptiles]); and
- animals fully protected in California (CFGC 3511 [birds], 4700 [mammals], and 5050 [reptiles and amphibians].

Based on the USFWS (2009) list for the quadrangles within the study area and Sacramento, Solano, and Yolo Counties, a review of CNDDB (2009) occurrences within a 10-mile radius of the study area, and personal observations, 35 special-status wildlife species were identified as having potential to occur within the study area and surrounding region (Table 3.10-2). Of these, 20 have low to no potential to occur because the study area is outside the species' known range or suitable habitat is absent. The remaining 15 could occur in the study area and are described in more detail below.

Table 3.10-2. Special-Status Wildlife Species with Potential to Occur in the Study Area

Common and Scientific Names	Status[a] Federal/State/ Other	Geographic Distribution	Habitat Requirements	Potential Occurrence in Study Area
Invertebrates				
Delta green ground beetle *Elaphrus viridus*	T/–/–	Restricted to Olcott Lake and other vernal pools at Jepson Prairie Preserve, Solano County	Sparsely vegetated edges of vernal lakes and pools; occur up to 250 feet from pools	None. Study area is outside of the species' range
Valley elderberry longhorn beetle *Desmocerus californicus dimorphus*	T/–/–	Stream side habitats below 3,000 feet throughout the Central Valley	Riparian and oak savanna habitats with elderberry shrubs; elderberries are the host plant	High. Known occurrences within the study area
Conservancy fairy shrimp *Branchinecta conservatio*	E/–/–	Disjunct occurrences in Solano, Merced, Tehama, Ventura, Butte, and Glenn Counties	Large, deep vernal pools in annual grasslands	None. Study area is outside of the species' range
Vernal pool fairy shrimp *Branchinecta lynchi*	T/–/–	Central Valley, central and south Coast Ranges from Tehama County to Santa Barbara County. Isolated populations also in Riverside County	Common in vernal pools; also found in sandstone rock outcrop pools	Low. No suitable habitat in the study area
Vernal pool tadpole shrimp *Lepidurus packardi*	E/–/–	Shasta County south to Merced County	Vernal pools and ephemeral stock ponds	Low. No suitable habitat in the study area
Lange's metalmark butterfly *Apodemia mormo langei*	E/–/–	Once found throughout the Antioch Dunes; range now reduced to less than 10 acres of Antioch Dunes in Contra Costa County	Limited to dense to moderately dense patches of food plant, wild buckwheat, in stabilized sand dunes	None. Study area is outside of the species' range
Amphibians				
California tiger salamander *Ambystoma californiense*	T/SSC/–	Central Valley, including Sierra Nevada foothills, up to approximately 1,000 feet, and coastal region from Butte County south to northeastern San Luis Obispo County.	Small ponds, lakes, or vernal pools in grass-lands and oak woodlands for larvae; rodent burrows, rock crevices, or fallen logs for cover for adults and for summer dormancy	None. No suitable habitat in the study area

Common and Scientific Names	Status[a] Federal/State/ Other	Geographic Distribution	Habitat Requirements	Potential Occurrence in Study Area
California red-legged frog *Rana aurora draytonii*	T/SSC/–	Found along the coast and coastal mountain ranges of California from Marin County to San Diego County and in the Sierra Nevada from Tehama County to Fresno County	Permanent and semi-permanent aquatic habitats, such as creeks and cold-water ponds, with emergent and submergent vegetation. May estivate in rodent burrows or cracks during dry periods	None. The study area is outside of this species' current known range. This species is believed to be extirpated from the valley floor
Reptiles				
Silvery legless lizard *Anniella pulchra pulchra*	–/SSC/–	Along the Coast, Transverse, and Peninsular Ranges from Contra Costa County to San Diego County with spotty occurrences in the San Joaquin Valley	Habitats with loose soil for burrowing or thick duff or leaf litter; often forages in leaf litter at plant bases; may be found on beaches, sandy washes, and in woodland, chaparral, and riparian areas	Low. No CNDDB occurrences within the study area. Potential habitat within the study area
Giant garter snake *Thamnophis couchi gigas*	T/T/–	Central Valley from the vicinity of Burrel in Fresno County north to near Chico in Butte County; has been extirpated from areas south of Fresno	Sloughs, canals, low gradient streams and freshwater marsh habitats where there is a prey base of small fish and amphibians; also found in irrigation ditches and rice fields; requires grassy banks and emergent vegetation for basking and areas of high ground protected from flooding during winter	Moderate to high. CNDDB occurrences within 3 miles of study area. Suitable habitat within study area
Western pond turtle *Actinemys marmorata*	–/SSC/–	Occurs from the Oregon border of Del Norte and Siskiyou Counties south along the coast to San Francisco Bay, inland through the Sacramento Valley, and on the western slope of Sierra Nevada	Occupies ponds, marshes, rivers, streams, and irrigation canals with muddy or rocky bottoms and with watercress, cattails, water lilies, or other aquatic vegetation in woodlands, grasslands, and open forests	High. Species observed within study area in ponds west of South River Road

Common and Scientific Names	Status[a] Federal/State/ Other	Geographic Distribution	Habitat Requirements	Potential Occurrence in Study Area
Birds				
Double-crested cormorant *Phalacrocorax auritus* (rookery site)	–/SSC/–	Winters along the entire California coast and inland over the Coast Ranges into the Central Valley from Tehama County to Fresno County; a permanent resident along the coast from Monterey County to San Diego County, along the Colorado River, Imperial, Riverside, Kern and King Counties, and the islands off San Francisco; breeds in Siskiyou, Modoc, Lassen, Shasta, Plumas, and Mon Counties; also breeds in the San Francisco Bay Area and in Yolo and Sacramento Counties	Rocky coastlines, beaches, inland ponds, and lakes; needs open water for foraging, and nests in riparian forests or on protected islands, usually in snags	Low. Observed foraging in the Sacramento River near the study area. No CNDDB nesting records within study area. Potential nesting habitat within study area
White-faced ibis *Plegadis chihi* (rookery site)	–/SSC/–	Both resident and winter populations on the Salton Sea and in isolated areas in Imperial, San Diego, Ventura, and Fresno Counties; breeds at Honey Lake, Lassen County, at Mendota Wildlife Management Area, Fresno County, and near Woodland, Yolo County	Prefers freshwater marshes with tules, cattails, and rushes, but may nest in trees and forage in flooded agricultural fields, especially flooded rice fields	Low. No CNDDB nesting records within study area. Low quality nesting habitat within study area
California black rail *Laterallus jamaicensis coturniculus*	–/T/–	Permanent resident in the San Francisco Bay and eastward through the Delta into Sacramento and San Joaquin Counties; small populations in Marin, Santa Cruz, San Luis Obispo, Orange, Riverside, and Imperial Counties	Tidal salt marshes associated with heavy growth of pickleweed; also occurs in brackish marshes or freshwater marshes at low elevations	None. No suitable habitat within study area

Common and Scientific Names	Status[a] Federal/State/ Other	Geographic Distribution	Habitat Requirements	Potential Occurrence in Study Area
California clapper rail *Rallus longirostris obsoletus*	E/E/–	Marshes around the San Francisco Bay and east through the Delta to Suisun Marsh	Restricted to salt marshes and tidal sloughs; usually associated with heavy growth of pickle-weed; feeds on mollusks removed from the mud in sloughs	None. Study area is outside of the species' range
Mountain plover *Charadrius montanus*	PT/SSC/–	Does not breed in California; in winter, found in the Central Valley south of Yuba County, along the coast in parts of San Luis Obispo, Santa Barbara, Ventura, and San Diego Counties; parts of Imperial, Riverside, Kern, and Los Angeles Counties	Occupies open plains or rolling hills with short grasses or very sparse vegetation; nearby bodies of water are not needed; may use newly plowed or sprouting grainfields	None. Species does not breed within study area.
Western snowy plover (inland population) *Charadrius alexandrinus nivosus*	–/SSC/–	Nests at inland lakes throughout northeastern, central, and southern California, including Mono Lake and Salton Sea	Barren to sparsely vegetated ground at alkaline or saline lakes, reservoirs, ponds and riverine sand bars; also along sewage, salt-evaporation, and agricultural waste-water ponds	None. No suitable nesting habitat within the study area
Northern harrier *Circus cyaneus*	–/SSC/–	Occurs throughout lowland California. Has been recorded in fall at high elevations	Grasslands, meadows, marshes, and seasonal and agricultural wetlands	Moderate. No CNDDB nesting records within the study area. Suitable nesting habitat in study area
White-tailed kite *Elanus leucurus*	–/FP/–	Lowland areas west of Sierra Nevada from the head of the Sacramento Valley south, including coastal valleys and foothills to western San Diego County at the Mexico border	Low foothills or valley areas with valley or live oaks, riparian areas, and marshes near open grasslands for foraging	Moderate. No CNDDB nesting records within the study area. Suitable nesting habitat in study area
Swainson's hawk *Buteo swainsoni*	–/T/–	Lower Sacramento and San Joaquin Valleys, the Klamath Basin, and Butte Valley. Highest nesting densities occur near Davis and Woodland, Yolo County.	Nests in oaks or cottonwoods in or near riparian habitats. Forages in grasslands, irrigated pastures, and grain fields.	High. CNDDB nesting records within study area

Common and Scientific Names	Status[a] Federal/State/ Other	Geographic Distribution	Habitat Requirements	Potential Occurrence in Study Area
Western burrowing owl *Athene cunicularia hypugea*	–/SSC/–	Lowlands throughout California, including the Central Valley, northeastern plateau, southeastern deserts, and coastal areas. Rare along south coast	Level, open, dry, heavily grazed or low stature grassland or desert vegetation with available burrows	High. CNDDB nesting records within study area
Western yellow-billed cuckoo *Coccyzus americanus occidentalis*	–/E/–	Nests along the upper Sacramento, lower Feather, south fork of the Kern, Amargosa, Santa Ana, and Colorado Rivers	Wide, dense riparian forests with a thick understory of willows for nesting; sites with a dominant cottonwood overstory are preferred for foraging; may avoid valley-oak riparian habitats where scrub jays are abundant	None. No suitable nesting habitat within the study area; forests in study area are dominated by valley oak and contain abundant scrub jays
Loggerhead shrike *Lanius ludovicianus*	–/SSC/–	Resident and winter visitor in lowlands and foothills throughout California; rare on coastal slope north of Mendocino County, occurring only in winter	Prefers open habitats with scattered shrubs, trees, posts, fences, utility lines, or other perches	Moderate. No CNDDB nesting records within the study area. Suitable nesting habitat in study area
Tricolored blackbird *Agelaius tricolor*	–/SSC/–	Permanent resident in the Central Valley from Butte County to Kern County; breeds at scattered coastal locations from Marin County south to San Diego County and at scattered locations in Lake, Sonoma, and Solano Counties; rare nester in Siskiyou, Modoc, and Lassen Counties	Nests in dense colonies in emergent marsh vegetation, such as tules and cattails, or upland sites with blackberries, nettles, thistles, and grain fields; habitat must be large enough to support 50 pairs; probably requires water at or near the nesting colony	High. CNDDB nesting records within study area

Common and Scientific Names	Status[a] Federal/State/ Other	Geographic Distribution	Habitat Requirements	Potential Occurrence in Study Area
Yellow-headed blackbird *Xanthocephalus xanthocephalus*	–/SSC/–	Locally numerous in the Klamath Basin, Modoc Plateau, Great Basin desert, and large mountain valleys in northeastern California; and in the San Joaquin Valley. Common breeders in the Colorado River valley, the Salton Sink, and the western Mojave desert; scarce in the Sacramento Valley and along the southern coast in Los Angeles, Riverside, and San Bernardino counties.	Nest in marshes with tall emergent vegetation, such as tules or cattails, generally in open areas and edges over relatively deep water. Breeding marshes often on edges of deep water bodies such as lakes, reservoirs, and or larger ponds	Moderate. CNDDB nesting records approximately 4.5 miles from the study area. Suitable nesting habitat in study area
Purple martin *Progne subis*	–/SSC/–	Coastal mountains south to San Luis Obispo County, west slope of the Sierra Nevada, and northern Sierra and Cascade ranges. Absent from the Central Valley except in Sacramento. Isolated, local populations in southern California	Nests in abandoned woodpecker holes in oaks, cottonwoods, and other deciduous trees in a variety of wooded and riparian habitats. Also nests in vertical drainage holes under elevated freeways and highway bridges	Moderate. CNDDB nesting records under nearby freeway. Suitable nesting habitat in study area
Bank swallow *Riparia riparia*	–/T/–	Occurs along the Sacramento River from Shasta County to Sacramento County, along the Feather and lower American Rivers, in the Owens Valley; and in the plains east of the Cascade Range in Modoc, Lassen, and northern Siskiyou Counties. Small populations near the coast from San Francisco County to Monterey County	Nests in bluffs or banks, usually adjacent to water, where the soil consists of sand or sandy loam	Moderate. No CNDDB nesting records within study area. Limited suitable nesting habitat along portions of the Sacramento River within the study area
Saltmarsh common yellowthroat *Geothlypis trichas sinuosa*	–/SSC/–	Found only in the San Francisco Bay Area in Marin, Napa, Sonoma, Solano, San Francisco, San Mateo, Santa Clara, and Alameda Counties	Freshwater marshes in summer and salt or brackish marshes in fall and winter; requires tall grasses, tules, and willow thickets for nesting and cover	None. Study area is outside of the species' range

Common and Scientific Names	Status[a] Federal/State/ Other	Geographic Distribution	Habitat Requirements	Potential Occurrence in Study Area
Grasshopper sparrow *Ammodramus savannarum*	–/SSC/–	Summer resident in the foothills of the Sierra Nevada and Coast Range from Mendocino and Trinity counties south to San Diego County.	Dry, dense grasslands with a variety of grasses and tall forbs and scattered shrubs.	Low. No CNDDB nesting records within study area. Potential nesting habitat within study area
Suisun song sparrow *Melospiza melodia maxillaris*	–/SSC/–	Restricted to the extreme western edge of the Delta, between the cities of Vallejo and Pittsburg near Suisun Bay	Brackish and tidal marshes supporting cattails, tules, various sedges, and pickleweed	None. Study area is outside of the species' range
Mammals				
Hoary bat *Lasurius cinerius*	–/SSC/–	Occurs throughout California from sea level to 13,200 feet	Primarily found in forested habitats. Also found in riparian areas and in park and garden settings in urban areas. Day roosts within foliage of trees	High. Reported in CNDDB to occur within study area. Suitable roosting habitat in study area
Pallid bat *Antrozous pallidus*	–/SSC/FSS, WBWG: High priority	Occurs throughout California except the high Sierra from Shasta to Kern County and the northwest coast, primarily at lower and mid-level elevations	Occurs in a variety of habitats from desert to coniferous forest. Most closely associated with oak, yellow pine, redwood, and giant sequoia habitats in northern California and oak woodland, grassland, and desert scrub in southern California. Relies heavily on trees for roosts	Moderate. Not reported to occur within study area; known to occur within 10 miles of the study area
Western red bat *Lasiurus blossevillii*	–/–/FSS, WBWG: High priority	Scattered throughout much of California at lower elevations	Found primarily in riparian and wooded habitats. Occurs at least seasonally in urban areas. Day roosts in trees within the foliage. Found in fruit orchards and sycamore riparian habitats in the central valley	Moderate. Not reported to occur within study area; known to occur within 10 miles of the study area
Salt marsh harvest mouse *Reithrodontomys raviventris*	E/E, FP	San Francisco, San Pablo, and Suisun Bays; the Delta	Salt marshes with a dense plant cover of pickle-weed and fat hen; adjacent to an upland site	None. Study area is outside of the species' range

Common and Scientific Names	Status[a] Federal/State/ Other	Geographic Distribution	Habitat Requirements	Potential Occurrence in Study Area
American badger *Taxidea taxus*	–/SSC/–	In California, badgers occur throughout the state except in humid coastal forests of northwestern California in Del Norte and Humboldt Counties	Badgers occur in a wide variety of open, arid habitats but are most commonly associated with grasslands, savannas, mountain meadows, and open areas of desert scrub; the principal habitat requirements for the species appear to be sufficient food (burrowing rodents), friable soils, and relatively open, uncultivated ground	Low. One historic record (1938) reported 8 miles from the study area. Limited suitable habitat within study area

[a] Status explanations:

Federal

E = listed as endangered under the Federal Endangered Species Act
T = listed as threatened under the Federal Endangered Species Act
C = species for which USFWS has on file sufficient information on biological vulnerability and threat(s) to support issuance of a proposed rule to list, but issuance of the proposed rule is precluded
– = no listing

State

E = listed as endangered under the California Endangered Species Act
T = listed as threatened under the California Endangered Species Act
FP = fully protected under the California Fish and Game Code
SSC = species of special concern in California
– = no listing

Western Bat Working Group (WBWG) Available: <http://www.wbwg.org/spp_matrix.html>

High priority = species are imperiled or at high risk of imperilment.
Moderate priority= this designation indicates a level of concern that should warrant closer evaluation, more research, and conservation actions of both the species and possible threats. A lack of meaningful information is a major obstacle in adequately assessing these species' status and should be considered a threat.
Low priority = While there may be localized concerns, the overall status of the species is believed to be secure.

1

Valley Elderberry Longhorn Beetle

Valley elderberry longhorn beetle (VELB) is federally listed as threatened under ESA. The range of the beetle extends throughout the Central Valley of California and associated foothills, from the 3,000-foot-high contour in the east foothills, through the valley floor, to the watershed of the Central Valley in the west foothills (U.S. Fish and Wildlife Service 1999a). Elderberry shrubs are found in the remaining riparian forests and grasslands of the Central Valley and adjacent foothills. The beetle is often associated with various plant species, such as Freemont's cottonwood, California sycamore, willow, and oak (U.S. Fish and Wildlife Service 1999a).

Elderberry shrubs (*Sambucus* sp.) are the host plant for VELB and are a common component of the remaining riparian forests of the Central Valley. Elderberry shrubs are also common in upland habitats. Field surveys have found that adult VELB feed on elderberry foliage and perhaps flowers and are present from March through early June. It is during this time that the adults mate. The females lay their eggs, either singularly or in small clusters, in bark crevices or at the junction of stem and trunk or leaf petriole and stem. After hatching, a larva burrows into the stem of the elderberry where it creates a gallery, which it fills with grass and shredded wood. After the larva transforms into an adult beetle, it chews an exit hole and emerges from the elderberry. The life span of VELB ranges from 1 to 2 years. Studies of the spatial distribution of occupied shrubs suggest that the beetle is a poor disperser. (U.S. Fish and Wildlife Service 1999a.)

Several CNDDB (2009) records of VELB are reported to occur in the study area along the Sacramento River North and South Levee reaches. Though not reported to occur in other levee reaches within the study area, VELB has potential to occur wherever elderberry shrubs sized 1 inch or greater at ground level occur.

Giant Garter Snake

The giant garter snake is listed as threatened under the ESA and CESA. The giant garter snake is the largest garter snake, reaching a maximum total length of at least 64 inches. Dorsal background coloration varies from brownish to olive with a checkered pattern of black spots, separated by a yellow dorsal stripe and two light colored lateral stripes. (U.S. Fish and Wildlife Service 1999b.)

Giant garter snakes are endemic to wetlands in the Sacramento and San Joaquin Valleys and inhabit marshes, sloughs, ponds, small lakes, low-gradient streams and other waterways, and agricultural wetlands such as irrigation and drainage canals and rice fields, as well as the adjacent uplands. Essential habitat components consist of:

- adequate water during the species' active season (early spring through mid-fall) to provide food and cover;
- emergent herbaceous wetland vegetation, such as cattails and bulrushes, for escape cover and foraging habitat during the active season;
- upland habitat with grassy banks and openings in waterside vegetation for basking; and
- higher-elevation uplands for cover and refuge from floodwaters during the dormant season in winter. (U.S. Fish and Wildlife Service 1999b.)

The giant garter snake is extremely aquatic and rarely found away from water. Giant garter snakes actively forage in the water and retreat to water to escape from predators and when disturbed. The

predominant prey species include crayfish, carp (*Cyprinus carpio*), mosquitofish (*Gambusia affinis*), bullfrogs, and Pacific tree frogs. Giant garter snakes are typically absent from larger rivers and other water bodies that support introduced populations of large predatory fish and from wetlands with sand, gravel, or rock substrates. Riparian woodlands do not typically provide suitable habitat because of excessive shade, lack of basking sites, and absence of prey populations. (U.S. Fish and Wildlife Service 1999b.)

Giant garter snakes hibernate in small mammal burrows and other soil crevices located near aquatic habitat above prevailing flood levels throughout the winter months (November until early spring). They typically select burrows with sunny exposure along south- and west-facing slopes. Giant garter snakes also use burrows as refuge from extreme heat during their active period. The USGS Biological Resources Division has documented giant garter snakes using burrows in summer as much as 165 feet away from the marsh edge. Overwintering giant garter snakes have been documented using burrows as far as 820 feet from the edge of marsh habitat. (U.S. Fish and Wildlife Service 1999b.)

There are no CNDDB (2009) records for giant garter snakes within the study area, although there are several occurrences within 10 miles of the study area. The closest of these occurrences is located approximately 3 miles from the study area in a drainage canal. This record is labeled as sensitive and therefore provides no specifics on location or type of observation. Other recorded occurrences within 10 miles of the study area include records for one juvenile located in a drainage canal 1.5 miles south of Del Paso Road, one adult found within the Yolo Bypass 0.75 mile south of I-80, and numerous other records that are labeled as sensitive (California Natural Diversity Database 2009). Within the study area, emergent wetlands and open water areas in the Yolo Bypass have the highest potential to support giant garter snakes. Throughout the study area, other emergent wetlands and open water areas may provide suitable aquatic habitat, and upland areas adjacent to aquatic habitat may provide winter hibernacula for this species. All levee reaches within the study area have potential to support this species.

Western Pond Turtle

The western pond turtle is a California species of special concern. The western pond turtle is the only abundant turtle native to California (California Department of Fish and Game 2005). It was historically found in most Pacific slope drainages between the Oregon and Mexican borders. It is still found in suitable habitats west of the Sierra-Cascade crest (Jennings and Hayes 1994).

Western pond turtles require some slow-water aquatic habitat and are uncommon in high-gradient streams (Jennings and Hayes 1994). The banks of inhabited waters usually have thick vegetation, but basking sites such as logs, rocks, or open banks must also be present (California Department of Fish and Game 2005). Depending on the latitude, elevation, and habitat type, the western pond turtle may become inactive over winter or remain active year-round. Nest sites are typically found on slopes that are unshaded and have high clay or silt composition (Jennings and Hayes 1994). Eggs are laid from March to August, depending on local conditions, and incubation lasts from 73 to 80 days. Western pond turtles are omnivorous and feed on aquatic plant material, aquatic invertebrates, fishes, frogs, and even carrion (California Department of Fish and Game 2005).

CNDDB (2009) records do not indicate any western pond turtle occurrences within the study area; however, pond turtles have been incidentally observed in ponds west of South River Road, located adjacent to the Sacramento River South Levee reach, by ICF International biologists. Additionally, western pond turtle is recorded to occur 7 miles east of the study area in drainage at the McClellan Air Force Base. Throughout the study area, open water (including irrigation canals) and emergent

wetland habitats provide potentially suitable aquatic habitat, while annual grassland, riparian forest, and other upland areas adjacent to aquatic habitats provide potential winter hibernacula and nesting habitat. All levee reaches within the study area have potential to support this species.

Swainson's Hawk

Swainson's hawks are protected under the MBTA and are state-listed as threatened. Swainson's hawks inhabit grasslands, sage-steppe plains, and agricultural regions of western North America during the breeding season, and winter in grassland and agricultural regions from central Mexico to southern South America (England et al. 1997).

In California, the nesting distribution includes the Sacramento and San Joaquin Valleys, the Great Basin sage-steppe communities and associated agricultural valleys in extreme northeastern California, isolated valleys in the Sierra Nevada in Mono and Inyo Counties, and limited areas of the Mojave Desert region (California Department of Fish and Game 1994).

Since 1980, based on nesting records alone, populations in California appear relatively stable. However, continued agricultural conversion and practices, urban development, and water development have reduced available habitat for Swainson's hawks throughout their range in California; this habitat reduction could potentially result in a long-term declining trend. The status of populations, particularly with respect to juvenile survivorship, remains unclear.

In California, Swainson's hawk habitat generally consists of large, flat, open, undeveloped landscapes that include suitable grassland or agricultural foraging habitat and sparsely distributed trees for nesting (England et al. 1997). Foraging habitat includes open fields and pastures. Preferred foraging habitats for Swainson's hawk include alfalfa fields, fallow fields, low-growing row or field crops, rice fields during the non-flooded period, and cereal grain crops. Prey species include ground squirrels, California voles, pocket gophers, deer mice, reptiles, and insects (California Department of Fish and Game 2000; England et al. 1997).

Swainson's hawks usually nest in large native trees such as valley oak, cottonwood, and willows, although non-native trees such as eucalyptus (*Eucalyptus* spp.) are occasionally used. Nests occur in riparian woodlands, roadside trees, trees along field borders, isolated trees and small groves, trees in windbreaks, and trees on the edges of remnant oak woodlands. In some locales, urban nest sites have been recorded. The breeding season is typically March to August (England et al. 1997).

CNDDB (2009) records indicate that Swainson's hawks are known to nest within or adjacent to all levee reaches within the study area. Large trees located in and adjacent to the study area provide suitable nesting habitat, and row and field agricultural lands and grasslands provide suitable foraging habitat.

White-Tailed Kite

The white-tailed kite is protected under the MBTA and is a fully protected species under the CFGC. White-tailed kites were threatened with extinction in North America during the early 20th century. Populations recovered throughout its range in the United States from small populations that survived in California, Texas, and Florida. However, since the 1980s, many white-tailed kite populations have been declining, apparently because of loss of habitat and increased disturbance of nests. (Dunk 1995.)

The breeding season generally extends from early February through early August. White-tailed kites usually nest in large native trees, although non-native trees also are occasionally used. Nest trees are generally at the edge of wooded habitat next to open fields. Large trees in areas that have been developed may also be used, although the trees need to be close to open fields for foraging (Dunk 1995). White-tailed kites feed primarily on small mammals including voles (*Microtus sp.*), pocket mice (*Perognathus sp.*), and harvest mice (*Reithrodontomys megalotis*).

CNDDB (2009) records indicate white-tailed kite nesting occurrences within 10 miles of the study area. Large trees in and adjacent to the study area provide suitable nesting habitat, and agricultural fields and other open areas provide suitable foraging habitat. All levee reaches in the study area provide suitable nesting and foraging habitat for this species.

Loggerhead Shrike

The loggerhead shrike (*Lanius ludovicianus*) is designated as a California species of special concern. Loggerhead shrikes are a widespread species in North America, occurring from the southern Canadian provinces across most of the United States into Mexico (Yosef 1996). In California, loggerhead shrikes occur in open habitats with scattered shrubs, trees, posts, fences, utility lines, and other perches. Habitats include valley foothill forests, pinyon-juniper, desert riparian, and Joshua tree habitats (California Department of Fish and Game 2005). Loggerhead shrikes are adaptable to urban environments as long as preferred habitat characteristics and abundant prey supplies are present (Yosef 1996).

The loggerhead shrike is a predatory songbird. As opportunistic predators, loggerhead shrikes feed on a wide variety of prey, including insects, small mammals and birds, reptiles, amphibians, and occasionally carrion. Prey is often impaled on sharp objects such as thorns and barbed wire fences (Yosef 1996). Nesting habitat includes densely foliaged shrubs and trees near open habitats (California Department of Fish and Game 2005).

CNDDB (2009) records do not indicate any loggerhead shrike occurrences within 10 miles of the study area. Al levee reaches within the study area have potential to support nesting and foraging of this species.

Tricolored Blackbird

The tricolored blackbird is a California species of special concern. Within California, active breeding colonies occur in 46 California counties with the largest colonies in the Central Valley. In the Central Valley, breeding extends east into the foothills of the Sierra Nevada. Historically, most California colonies have been located in the Sacramento and San Joaquin Valleys, but habitat loss has reduced breeding considerably in this area in recent years (Beedy and Hamilton 1999). Tricolored blackbirds have three basic requirements for selecting their breeding colonies: open, accessible water; a protected nesting substrate, including either flooded vegetation or thorny/spiny vegetation; and a suitable foraging space providing adequate insect prey within a few miles of the nesting colony. They often change their nest locations from year to year. An increasing percentage of tricolored blackbirds are using Himalayan blackberry as well as dairies for nesting habitat (Beedy and Hamilton 1999).

Suitable breeding habitats within the Central Valley have been found to include emergent marsh areas with tules or cattail and upland habitats consisting of thistle, nettle, blackberry, wheat, and other shrubby upland substrates (Meese 2006). Foraging habitats in all seasons include annual

grasslands, wet and dry vernal pools and other seasonal wetlands, agricultural fields (e.g., large tracts of alfalfa with continuous mowing schedules and recently tilled fields), cattle feedlots, and dairies. Tricolored blackbirds also occasionally forage in riparian scrub habitats and along marsh borders. Weed-free row crops and intensively managed vineyards and orchards do not serve as regular forage sites (Beedy and Hamilton 1999).

CNDDB (2009) indicated one tricolored blackbird nesting site within the study area, located near the Port of Sacramento, in the vicinity of the Port North Levee reach. The birds were reported to be nesting in an area containing thistle and mustard in 1969 and 1974. The size of this population was not reported. Emergent wetlands, Himalayan blackberry brambles, hay and grain fields, and grasslands containing dense forbs within the study area provide suitable nesting habitat. All levee reaches within the study area have potential to support this species.

Yellow-Headed Blackbird

Yellow-headed blackbird is a California species of special concern. This species breeds in central California and is a year-round resident in southern California. Nests are built in emergent vegetation of deep-water palustrine wetlands. The species also constructs nests over deeper water, primarily in cattails (*Typha* spp.), bulrushes (*Scirpus* spp.), or reeds (*Phragmites* spp.), often in the same wetlands as nesting red-winged blackbirds. Yellow-headed blackbird forages within wetlands and surrounding grasslands, as well as open agricultural areas—harvested grain fields, plowed fields, meadows, and pastures—or savanna. The species is not known to inhabit the forest interior, but it may use forest edges for roosting, loafing, or foraging. (Twedt and Richard 1995.)

During the breeding season, yellow-headed blackbirds feed primarily on aquatic prey, feeding aquatic insects to nestlings. During the post-breeding season, the species is known to consume primarily cultivated grains and weed seeds, often foraging in large flocks. (Twedt and Richard 1995.)

CNDDB (2009) indicates a historic (1899) occurrence for this species along the Sacramento River 4 miles east of the study area. Emergent wetlands within the study area provide suitable nesting habitat. All levee reaches have potential to support nesting and foraging of this species.

Purple Martin

Purple martin is a California species of special concern. This species breeds locally along eastern slopes of Cascade Mountains of California south to extreme southwestern California. The species winters in South America in lowlands east of the Andes south to northern Argentina (rarely) and southern Brazil. Purple martin is the largest swallow in North America and among the largest in the world. These martins inhabit montane forest or Pacific lowlands, restricted to areas with dead snags containing woodpecker holes, generally patchy and local in occurrence. This species is reported to typically avoid deserts and grasslands. (Brown 1997.)

Purple martin is a diurnal, aerial feeder that feeds on insects at higher elevations than other swallows, sometimes up to 490 feet. Because of the height of foraging, individuals are rarely observed foraging, with the exception being late afternoons and near dusk when birds feed low and close to nest sites. The species presumably ranges over areas immediately surrounding nest site, although there is no information on typical travel distance while foraging. Cold, rainy weather in spring forces purple martins, especially migrants, to feed low over ponds and lakes, apparently in pursuit of aquatic insects along water surface. (Brown 1997.)

The nearest CNDDB (2009) occurrence for this species is for a colony nesting in weep holes under the I-5 Freeway overpass at I Street within 1 mile of the Sacramento River North and South Levee reaches. An estimated 21 to 29 pairs of birds nest at this location. Numerous other occurrences are reported within a 10-mile radius for colonies nesting under freeway or street overpasses. These include records located just north of Arcade Creek where I-80 crosses Roseville Road; Marconi Avenue overpass of Auburn Boulevard and the Union Pacific and light rail tracks; El Camino overpass of the Union Pacific and light rail tracks; U.S. 50 at Redding Road and the Union Pacific and light rail tracks; between 65th Street and Howe Avenue; U.S. 50 from 34th Street to Stockton Boulevard; Capital City Freeway (Business I-80) between R and S Streets; the east bound U.S. 50 off-ramp to southbound SR 99 and northbound SR 99 off-ramp to eastbound U.S. 50; Sutterville Road over the Union Pacific rail yard west of SR 99; and U.S. 50 between 18th and 20th Streets. (California Natural Diversity Database 2009.)

Suitable nesting habitat for this species occurs in the riparian forest and other woodland and forest areas throughout the study area.

Bank Swallow

The bank swallow is a state-listed threatened species. Within California, bank swallow is a regular breeder from Monterey to San Francisco County and in northern California including Siskiyou, Shasta, and Lassen Counties and along Sacramento River from Shasta County south to Yolo County. Bank swallows nest in erodible soils on vertical or near-vertical banks and bluffs in lowland areas dominated by rivers, streams, lakes, and oceans. Based on the often ephemeral nature of nesting areas, bank swallow has low nest site fidelity. Foraging habitats surrounding nesting colony sites include wetlands, open water, grasslands, riparian forests, agricultural lands, shrublands, and occasionally upland woodlands. (Garrison 1999.)

Bank swallow is an aerial feeder from dawn to dusk that takes flying or jumping insects almost exclusively on the wing. The species is reported to occasionally eat terrestrial and aquatic insects or larvae and less often to consume vegetable matter. Bank swallow may feed on the ground where high concentrations of suitable insect prey are present. (Garrison 1999.)

There are no CNDDB (2009) occurrences for this species within the study area. Numerous nesting records for this species occur approximately 5 miles from the study area along the American River. Additionally, this species is recorded to nest approximately 12 miles north of the study area along the Sacramento River. Within the study area, suitable breeding habitat includes areas along the Sacramento River where banks are vertical to near-vertical. Limited suitable nesting habitat therefore occurs along the Sacramento River North and South Levee reaches of the study area.

Northern Harrier

The northern harrier is a California species of special concern and is protected under the MBTA and CFGC 3503 and 3503.5. The northern harrier is a medium-sized hawk raptor of upland grasslands and fresh- and saltwater marshes. In California, northern harriers are a permanent resident of the northeastern plateau, coastal areas, and Central Valley (Macwhirter and Bildstein 1996). Northern harriers breed in California in the Central Valley and Sierra Nevada (California Department of Fish and Game 2005).

Northern harriers frequent meadows, grasslands, desert sinks, open rangelands, and fresh- and saltwater emergent wetlands; they are seldom found associated with wooded habitats. Harriers feed

mostly on voles and other small mammals, birds, frogs, small reptiles, crustaceans, insects, and rarely on fish (California Department of Fish and Game 2005). Harriers mostly nest in emergent wetland or along rivers or lakes, but may nest in grasslands, grain fields, or sagebrush flats several miles from water (Macwhirter and Bildstein 1996). The nest is built of a large mound of sticks on wet areas and a smaller cup of grasses on dry sites.

CNDDB (2009) records do not indicate any northern harrier occurrences within 10 miles of the study area. Non-orchard agricultural fields and annual grasslands provide suitable foraging habitat, and the annual grassland, irrigated pasture, and emergent wetland habitat within the study area provides suitable nesting and foraging habitat. All levee reaches within the study area have potential to support nesting and forging of this species.

Western Burrowing Owl

Western burrowing owls are a California species of special concern and are protected under the MBTA. Western burrowing owls were formerly a common permanent resident throughout much of California, but population declines became noticeable by the 1940s and have continued to the present. Farming has taken a major toll on western burrowing owl populations and their habitat by destroying nesting burrows and exposing breeders and their young to the toxic effects of pesticides. (Haug et al. 1993.)

Western burrowing owls prefers open, dry, short grassland habitats with few trees and are often associated with burrowing mammals such as California ground squirrels. They occupy burrows, typically abandoned by ground squirrels or other burrowing mammals, but may also use artificial burrows such as abandoned pipes, culverts, and debris piles (California Department of Fish and Game 1995; Haug et al. 1993). Prey includes arthropods, amphibians, small reptiles, small mammals, and birds, particularly horned larks (Haug et al. 1993).

The breeding season usually extends from late February through August. Western burrowing owls often nest in roadside embankments, on levees, and along irrigation canals. This species is more diurnal than most owls and can often be observed during the day standing outside the entrance to its burrow. (Haug et al. 1993.)

CNDDB (2009) indicated two nesting burrowing owl records within the study area. These records are located adjacent to the DWSC 0.9 mile southeast of Greens Lake on the east side of the Yolo Bypass, within the DWSC West Levee reach, and 0.2 mile southwest of the intersection of U.S. Highway 84 and Harbor Boulevard, within the Sacramento River North Levee reach.

Numerous other nesting occurrences occur within 10 miles of the study area. The closest of these include nesting records located in the vicinity of McKinley Park near Sacramento State University and the northwest corner of Sacramento Executive Airport. The levees provide suitable nesting habitat where ground squirrel burrows are present and open areas near suitable nesting habitat provide suitable foraging habitat. All levee reaches within the study area have potential to support nesting and foraging of this species.

Hoary Bat

The hoary bat is a California species of special concern. Hoary bats are found primarily in forested habitats, including riparian forests, and may occur in park and garden settings in urban areas (Brown and Pierson 1996). Habitats that are suitable for providing maternity roosts include all

woodlands that have medium- to large-sized trees with dense foliage. Females and young tend to roost at higher sites in trees (California Department of Fish and Game 2005).

CNDDB (2009) records indicate a hoary bat observation within the study area in the Sacramento River North Levee reach. Suitable habitat in the study area occurs in riparian forests and other forests and woodlands, and all levee reaches in the study area have potential to support this species.

Western Red Bat

Western red bat is a California species of special concern that occurs throughout much of California at lower elevations. It is found primarily in riparian and wooded habitats but also occurs seasonally in urban areas (Brown and Pierson 1996). Western red bats roost in the foliage of trees that are often located on the edge of habitats adjacent to streams, fields, or urban areas. This species breeds in August and September, and young are born in May through July (Zeiner et al. 1990b).

CNDDB (2009) records indicate one western red bat observation within 10 miles of the study area. Suitable habitat within the study area occurs in riparian forests and other forests and woodlands, and all levee reaches in the study area have potential to support this species.

Pallid Bat

The pallid bat is a California species of special concern. Pallid bats are found in a variety of habitats but are particularly associated with oak woodlands, ponderosa pine, redwood, and sequoia habitats in central and northern California. Pallid bats have a high reliance on trees for day roosts. (Brown and Pierson 1996.)

CNDDB (2009) records indicate one pallid bat observation within 10 miles of the study area. Suitable habitat within the study area occurs in riparian forests and other forests and woodlands, and all levee reaches within the study area have potential to support this species.

3.10.3 Environmental Consequences

This section describes the effect analysis relating to wildlife for the proposed program. It describes the methods used to determine the effects of the program and lists the thresholds used to conclude whether an effect would be significant. How this effect differs among reaches is discussed, if applicable. Measures to mitigate (i.e., avoid, minimize, rectify, reduce, eliminate, or compensate for) significant effects accompany each effect discussion.

3.10.3.1 Assessment Methods

3.10.3.1.1 Effect Mechanisms

The following program-related activities could affect wildlife resources within the study area. These types of direct and indirect effects were used to assess effects on wildlife resources.

Direct Effects

Direct effects on wildlife could be caused by the following actions:

- vegetation clearing (including trees), grading, excavating/trenching, placement of rock slope protection, and paving activities during construction;
- temporary stockpiling and sidecasting of soil, construction materials, or other construction wastes;
- soil compaction, dust, and water runoff from the construction site;
- short-term construction-related noise (from equipment); and
- degradation of water quality in drainages and wetlands, resulting from construction runoff containing petroleum products.

Indirect Effects

Indirect effects on wildlife could e caused by the following actions:

- permanently altering light and noise levels;
- altering hydrology;
- causing damage through toxicity associated with herbicides, insecticides, and rodenticides;
- introducing pet and human disturbance (including trash dumping);
- increasing habitat for native competitors or predators; and
- introducing invasive non-native species.

3.10.3.2 Determination of Effects

For this analysis, an effect pertaining to wildlife resources was considered significant if it would result in any of the following environmental effects, which are based on professional practice and State CEQA Guidelines Appendix G (14 CCR 15000 et seq.).

- have a substantial adverse effect, either directly or through habitat modification, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations or by DFG or the USFWS;
- interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites;
- conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance;
- conflict with the provisions of an adopted habitat conservation plan, natural communities conservation plan, or other approved local, regional, or state habitat conservation plan; or
- contribute to a substantial reduction or elimination of species diversity or abundance.

Qualitative relationships between environmental conditions and life stage survival or wildlife resources are the basis of the effect assessment. Cause and effect relationships are identified for

assessment species, including the relationship between environmental conditions and habitat, and the effects of changes in habitat on survival.

The effect analysis below is qualitative and programmatic and is not based on site-specific information. The mitigation measures described for potential effects on sensitive biological resources have not been developed through formal consultation or coordination with resource agencies (e.g., DFG, USFWS, NMFS, and the USACE). As part of the environmental analysis for project phases, the program proponent will contact agencies as part of the environmental compliance process to determine specific compensatory mitigation for effects on wetlands, state- and federally listed species, and riparian habitats. Additional mitigation measures may also be identified as conditions of future action permits (e.g., a BO, Section 7 Incidental Take Statement, or Section 1602 Streambed Alteration Agreement).

3.10.3.3 Effects and Mitigation Measures

3.10.3.3.1 No Action Alternative

The No Action Alternative is a continuation of the existing deficiencies along the nine levee reaches (i.e., no levee alternatives would be implemented to meet the minimum level of acceptable flood protection). Current levee maintenance activities such as mowing and application of herbicides would continue. No direct or indirect construction-related effects on wildlife or their habitats would occur.

Without levee improvements, there is the continued risk of levee failure. A catastrophic levee failure would result in flooding and inundation that could significantly affect wildlife and their upland or wetland habitats by physical displacement, mortality, or destruction of habitat. In addition, cleanup and repair activities could result in physical displacement for extended periods of time and significant effects on habitat. If a flood event were to occur along the Sacramento River corridor, the narrow band of valuable riparian habitat located along the levees could be damaged. Given the importance of this riparian corridor for numerous special-status species and for the pacific flyway in general, loss or fragmentation of this habitat would be a significant effect, and it could take decades for a mature riparian forest to re-establish itself in the affected areas, if USACE vegetation policies allow re-establishment at all. Given the uncertainty of the occurrence or magnitude of such an event, potential effects on wildlife and their habitats cannot be quantified based on available information.

As discussed under the No Action Alternative in Section 3.8, Vegetation and Wetlands, compliance with the vegetation-free zone as described in the USACE's Vegetation Guidance would be required with program implementation but also in the absence of program implementation. Compliance with the vegetation guidance could result in the removal of a substantial amount of vegetation, including riparian vegetation that supports SRA habitat. This would result in significant effects on fish and their habitats. However, given the uncertainties surrounding the potential for variances and implementation of the vegetation guidance, any estimation of effects would be speculative.

3.10.3.3.2 Flood and Recreation Program Alternatives

Effect WILD-1: Permanent Loss of Riparian Habitat for Special-Status Wildlife Species as a Result of Levee Vegetation Removal

All levee alternatives proposed under the program would follow USACE's policies regarding vegetation on levees, which forbid all woody vegetation on the crown, slopes, and within 15 feet of the waterside and landside levee toes. These zones would be maintained free of woody vegetation in perpetuity. Thus, the removal of a substantial amount of mature trees and vegetation from the banks of the Sacramento River may be required.

Permanent loss of the woody vegetation in compliance with USACE's policies would result in a significant effect on riparian habitat. The full extent of this effect is dependent on what portions of the existing levee would be officially deemed as the levee prism according to USACE. In some cases, the current levees are wider than the minimum requirements (or may become wider with the implementation of program alternatives such as an adjacent levee raise) and existing vegetation may fall outside of the vegetation free zone. Moreover, dependent on site conditions, variances that would allow vegetation to remain may be issued on a case-by-case basis.

Riparian habitats, particularly in the Central Valley, provide essential nesting and cover habitat for numerous special-status wildlife species with known or potential occurrence in the study area, including VELB, western pond turtle, Swainson's hawk, white-tailed kite, hoary bat, western red bat, and pallid bat. VELB are dependent on riparian habitats containing elderberry shrubs, which are the host plants for VELB and are needed to complete the insect's life cycle. Western pond turtle use riparian vegetation for nesting and cover during the breeding season and for overwintering. Swainson's hawk and white-tailed kite require mature trees for nesting, which are most prevalent within the Central Valley within riparian habitats, particularly those along the Sacramento River. Though human-made structures are often used for day and night roosting by special-status bats such as hoary bat, western red bat, and pallid bat, riparian habitats provide essential natural roosting and cover habitat adjacent to important foraging areas.

Therefore, removal of woody riparian vegetation along levees, in accordance with USACE's vegetation policies, would result in the loss of substantial key habitats needed to support special-status species in the area. Because the riparian habitats within the study area are some of the most extensive in the Central Valley, the loss of these habitats would be a significant effect. Implementation of VEG-MM-1 would reduce the effect on species in the area over time but because mature riparian habitat cannot be replaced in the short term, this effect would still be significant. In addition, depending on the intensity of the effect, implementation of Mitigation Measure VEG-MM-1 may reduce but not fully compensate for effects. Therefore, this effect is potentially significant and unavoidable.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall ▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Closure structure ▪ Interior drain ▪ Jet grouting ▪ Relief wells	▪ Seepage berm ▪ Sheet pile wall ▪ Slurry cutoff wall ▪ Slope flattening ▪ Stability berm ▪ Rock slope protection ▪ Setback levee ▪ Vegetation removal
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect would occur in all nine program reaches. The degree of this effect would be greater in the Sacramento River North and South Levee reaches, Port North and South Levee reaches, and the South Cross Levee because these reaches support the greatest amount of riparian habitat and associated wildlife species in comparison to the other reaches in the study area.

Effect WILD-1 Finding	With Mitigation
Significant	Potentially significant and unavoidable

Mitigation

Mitigation Measure VEG–MM-1: Compensate for the Disturbance or Removal of Riparian Habitat

See Section 3.8, Vegetation and Wetlands, for a full description of this measure.

Effect WILD-2: Disturbance or Loss of Special-Status Wildlife Species and Their Habitats as a Result of Construction

The study area has potential to support numerous special-status wildlife species. As described above, the study area contains documented occurrences of VELB, Swainson's hawk, western burrowing owl, tricolored blackbird, and hoary bat. In addition, other special-status wildlife species that have the potential to occur within the study area because of the presence of suitable habitat include giant garter snake, western pond turtle, white-tailed kite, northern harrier, loggerhead shrike, yellow-headed blackbird, purple martin, bank swallow, western red bat, and pallid bat.

Construction in the study area could result in the direct loss or indirect disturbance of special-status wildlife or their habitats that are known to occur or could occur in the study area and surrounding region (Table 3.10-2). Effects on special-status wildlife or their habitat could result in a substantial reduction in local population size, lowered reproductive success, or habitat fragmentation.

Significant effects on special-status wildlife associated with levee alternative projects include, but are not limited to:

- direct mortality resulting from the movement of equipment and vehicles through the action area;
- direct mortality from the collapse of burrows, resulting from soil compaction;
- loss of breeding and foraging habitat resulting from the filling of emergent wetlands and open water areas;
- loss of breeding, foraging, or refuge habitat resulting from the permanent removal of grasslands, non-orchard agricultural lands, pasturelands, riparian vegetation, and other woodland and forest habitats;
- abandoned eggs or young and subsequent nest failure for special-status and nesting birds, including raptors, as a result of construction-related noises;
- loss of suitable foraging habitat for special-status raptor species; and
- loss or disruption of migration corridors.

Depending on which special-status wildlife species (listed versus unlisted) are affected and the extent of the effect, these species could experience significant effects. However, implementation of Mitigation Measures VEG-MM-1 and VEG-MM-8 and WILD-MM-1 through WILD-MM-4 would reduce effects. The final determination would need to be made on an action-by-action basis for future phases of the program in consultation with the applicable resource regulatory agency (USFWS and/or DFG). In addition, as discussed above under Effect WILD-1 regarding the limitations caused by the vegetation- free zone, and dependent upon the amount of the effect, implementation of Mitigation Measure VEG-MM-1 may reduce but not fully compensate for effects. This effect would, therefore, be potentially significant and unavoidable.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall ▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Closure structure ▪ Interior drain ▪ Jet grouting ▪ Relief wells	▪ Seepage berm ▪ Sheet pile wall ▪ Slurry cutoff wall ▪ Slope flattening ▪ Stability berm ▪ Rock slope protection ▪ Setback levee ▪ Vegetation removal
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect would occur in all nine program reaches. The degree of this effect would be greater in the

Sacramento River North and South Levee reaches, Port North and South Levee reaches, and the South Cross Levee because these reaches support the greatest amount of riparian habitat and associated wildlife species in comparison to the other reaches in the study area.

Effect WILD-2 Finding	With Mitigation
Significant	Less than significant to potentially significant and unavoidable

Mitigation

Mitigation Measure VEG–MM-1: Compensate for the Disturbance or Removal of Riparian Habitat

See Section 3.8, Vegetation and Wetlands, for a full description of this measure.

Mitigation Measure VEG-MM-8: Compensate for the Loss of Wetlands and Other Waters

See Section 3.8, Vegetation and Wetlands, for a full description of this measure.

Mitigation Measure WILD-MM-1: Document Special-Status Wildlife Species and Their Habitats

The program proponent will retain a qualified wildlife biologist to document the presence or absence of suitable habitat for special-status wildlife. The following steps will be implemented to document special-status wildlife and their habitats:

- **Review existing information**. The wildlife biologist will review existing information to develop a list of special-status wildlife species that could occur in the action area. The following information will be reviewed as part of this process: the USFWS special-status species list for the action region, DFG's CNDDB, previously prepared environmental documents, city and county general plans, habitat conservation plans and natural community conservation plans (if there are any adopted by the time the action is constructed), and USFWS-issued BOs for previous actions.
- **Coordinate with state and Federal agencies**. The wildlife biologist will coordinate with the appropriate agencies (DFG and USFWS) to discuss wildlife resource issues in the action region and determine the appropriate levels of survey necessary to document special-status wildlife and their habitats.
- **Conduct field studies**. The wildlife biologist will evaluate existing habitat conditions and determine what levels of biological survey may be required. The type of survey required will depend on species richness, habitat type and quality, and the probability of special-status species occurring in a particular habitat type. Depending on the existing conditions in the action area and the proposed construction activity, one or a combination of the following levels of survey may be required:
    - **Habitat assessment.** A habitat assessment determines whether suitable habitat is present. This type of assessment can be conducted at any time of year and is used to assess and characterize habitat conditions and determine whether return surveys are necessary. If no suitable habitat is present, no additional surveys will be required.
    - **Conduct species-focused surveys.** Species-focused surveys (or target species surveys) will be conducted if suitable habitat is present for special-status wildlife and it is necessary to determine the presence or absence of the species in the action area. The surveys will focus

on special-status wildlife species that have the potential to occur in the region. The surveys will be conducted during a period when the target species are present and/or active.

- **Conduct protocol-level wildlife surveys.** The program proponent will comply with protocols and guidelines issued by responsible agencies for certain special-status species. USFWS and DFG have issued survey protocols and guidelines for several special-status wildlife species that could occur in the study area, including (but not limited to) VELB, Swainson's hawk, western burrowing owl, and giant garter snake. The protocols and guidelines may require that surveys be conducted during a particular time of year and/or time of day when the species is present and active. Many survey protocols require that only a USFWS- or DFG-approved biologist perform the surveys. The program proponent will coordinate with the appropriate state or Federal agency biologist before initiation of protocol-level surveys to ensure that the survey results will be valid. Because some species can be difficult to detect or observe, multiple field techniques may be used during a survey period, and additional surveys may be required in subsequent seasons or years as outlined in the protocol or guidelines for each species.

Mitigation Measure WILD-MM-2: Redesign the Action to Protect Special-Status Wildlife Habitat and Develop a Mitigation Monitoring Plan

This mitigation measure focuses on avoiding and minimizing all direct and indirect effects on special-status wildlife. The program proponent will implement the following measures to avoid and minimize effects on special-status wildlife and their habitats:

- Redesign or modify the action to avoid direct and indirect effects on special-status wildlife or their habitats, if feasible.
- Protect special-status wildlife and their habitat near the action site by installing environmentally sensitive area fencing around habitat features, such as seasonal wetlands, burrows, and nest trees. The environmentally sensitive area fencing or staking will be installed at a minimum distance from the edge of the resource as determined through coordination with state and Federal agency biologists (USFWS and DFG). The location of the fencing will be marked in the field with stakes and flagging and shown on the construction drawings. The construction specifications will contain clear language that prohibits construction-related activities, vehicle operation, material and equipment storage, and other surface-disturbing activities within the fenced environmentally sensitive area.
- Restrict construction-related activities to the non-breeding season for special-status wildlife species that could occur in the action area. Timing restrictions may vary depending on the species and could occur during any time of the year.
- Coordinate with the appropriate resource agencies to determine whether a monitoring plan for special-status wildlife is necessary as part of the program. If a monitoring plan is required, it will be developed and implemented in coordination with appropriate agencies and will include:
  - a description of each of the wildlife species and the suitable habitat for species that could occur at the action site,
  - the locations of known occurrences of special-status wildlife species within 5 miles of the action site,
  - the location and size of no-disturbance zones in and adjacent to environmentally sensitive areas for wildlife,

- directions on the handling and relocating of special-status wildlife species found on the action site that are in immediate danger of being destroyed, and
- notification and reporting requirements for special-status species that are identified on the action site.

Mitigation Measure WILD-MM-3: Coordinate with Resource Agencies and Develop Appropriate Wildlife Compensation Plans for Species Listed under ESA or CESA

If mitigation measure WILD-2 is not feasible and site-specific construction activities would result in significant effects on wildlife species listed under ESA and/or CESA, a compensation plan will be developed in coordination with the appropriate resource agency, or agency-approved compensation guidelines will be followed to reduce the effect. Compensation guidelines have been identified for several special-status wildlife species, including VELB, Swainson's hawk, burrowing owl, and giant garter snake. The amount of compensation will vary depending on the amount of habitat loss or degree of habitat disturbance anticipated. The compensation plan will be developed and implemented in coordination with the appropriate state or Federal agency and will involve identifying an agency-approved mitigation bank or mitigation site (on or off site); transplanting (elderberry shrubs), re-creating (burrows), and/or preserving additional habitat for special-status wildlife species; monitoring the mitigation site; and funding the management of the mitigation site.

Mitigation Measure WILD-MM-4: Avoid or Minimize Construction-Related Effects on Nesting Birds

To avoid removing or disturbing any active migratory bird nests, tree and shrub removal, other vegetation clearing, grading, and other construction activities will be conducted during the non-breeding season (generally September 1 through February14) or after a qualified biologist determines that fledglings have left an active nest.

If activities will be conducted during the breeding season (February 15 through August 31), a qualified biologist will be retained to conduct a breeding season survey for nesting birds.

The survey will be conducted for all trees and shrubs (and vertical banks along the Sacramento River for bank swallow) that will be removed or disturbed and any suitable nesting habitat within 500 feet of construction activities, including grading. Migratory bird nest surveys will be conducted no more than 48 hours from the initiation of program activities to confirm the absence of nesting.

If the biologist determines that the area surveyed does not contain any active nests, construction activities, including tree removal, can commence without any further mitigation for species. If active nests are found, the activities will not occur until nesting activities have ceased (i.e. after a qualified biologist determines that fledglings have left the nest) or DFG is contacted to determine an appropriate buffer area needed to protect nests from program activities.

Effect WILD-3: Disturbance or Loss of Common Wildlife Species as a Result of Construction

The study area contains both natural and constructed habitats that support numerous common wildlife species. These species include a wide variety of terrestrial and aquatic invertebrates, birds and raptors, amphibians, reptiles, and mammal, as listed in the Environmental Setting section.

Numerous common migratory bird species have potential to nest within the study area, including red-tailed hawk, red-shouldered hawk, great horned owl, American kestrel, white-tailed kite, and

red-winged blackbird. Common bats, including California myotis (*Myotis californicus*) and small-footed myotis (*Myotis subulatus*), also have potential to roost in trees and snags within the study area. Tree (and shrub) removal, other vegetation clearing, grading, or other construction activities could remove or cause abandonment of active bird nests or bat roosts. Within the study area, suitable nesting habitat for migratory birds occurs in riparian forests, other woodlands and forests, grasslands, and pasturelands. Similarly, riparian forests and other woodlands and forests contain suitable bat roosting habitat. Effects on bird species protected under the MBTA and CFGC and/or bat roosts protected by DFG would be significant. Implementation of Mitigation Measures WILD-MM-4 and WILD-MM-5 would reduce this effect to less than significant.

Other common wildlife species are not afforded protection under CEQA or NEPA because they are considered to be widespread and abundant. Effects on these species are therefore less than significant.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall ▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Closure structure ▪ Interior drain ▪ Jet grouting ▪ Relief wells	▪ Seepage berm ▪ Sheet pile wall ▪ Slurry cutoff wall ▪ Slope flattening ▪ Stability berm ▪ Rock slope protection ▪ Setback levee ▪ Vegetation removal
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect would occur in all nine program reaches. The degree of this effect would be greater in the Sacramento River North and South Levee reaches, Port North and South Levee reaches, and the South Cross Levee because these reaches support the greatest amount of riparian habitat and associated wildlife species in comparison to the other reaches in the study area.

Effect WILD-3 Finding	With Mitigation
Significant	Less than significant

Mitigation

Mitigation Measure WILD-MM-4: Avoid or Minimize Construction-Related Effects on Nesting Birds

Mitigation Measure WILD-MM-5: Conduct a Preconstruction Survey for Roosting Bats and Avoid or Mitigate Potential Effects

Prior to any tree trimming and removal activities, a qualified biologist will conduct a preconstruction survey to determine whether bats are present. Trees within 100 feet of construction areas will be surveyed to ensure that adjacent bat roosts are not disturbed. The survey will consist of a nighttime emergence survey of suitable trees for evidence (presence of guano or urine stains) of use by bats, and it will be conducted no more than 14 days prior to construction activities. If the biologist determines that the area surveyed does not contain any active roosts, activities may commence without any further mitigation. If active roosts are found, roosting structures will be retained, and the need for a construction buffer will be determined through consultation with DFG. If avoidance is not possible, DFG may require that bats be excluded from the habitat prior to start of the breeding and/or hibernation season. Compensatory mitigation of the loss of roosting habitat also will be determined through consultation with DFG but may include the construction and installation of suitable replacement habitat on site, such as bat houses.

Effect WILD-4: Disruption to Wildlife Movement Corridors as a Result of Construction

Within the program study area, all levee reaches may act as movement corridors for wildlife because of their adjacency to major waterways, which provide important resources for migrating or dispersing animals. During construction of levee alternatives, movement through program sites would likely be temporarily impeded either by the placement of physical barriers (fencing) used to protect resources outside of the construction footprint or because of the presence of construction noise, which would likely discourage animals from entering the area. The nine levee reaches within the study area are considered to have high value as movement corridors, and disruption of these areas could significantly affect the ability of animals to move through these areas. However, it is assumed that construction of levee alternatives within each reach would be staggered based on varying schedule constraints at each site, and thus all sites would not be impassible at one time. Additionally, it is assumed that construction at each site would most often be completed within 1 year, thereby creating only a temporary barrier to movement within a specific localized area. The function of levee reaches to act as movement corridors would therefore be disrupted temporarily during program construction within a localized area, but this function would be restored following the completion of program construction. Further, although different levee alternatives would alter the maximum height or width of levee reaches to varying degrees, it is assumed that no treatment would drastically reduce the passability, as compared to the current condition, at any of the nine levee reaches in the study area. Therefore, this potential effect would be less than significant.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Floodwall	▪ Seepage berm
	▪ Levee raise (in place)	▪ Sheet pile wall
	▪ Levee raise (adjacent)	▪ Slurry cutoff wall
	▪ Levee raise (full)	▪ Slope flattening
	▪ Closure structure	▪ Stability berm
	▪ Interior drain	▪ Rock slope protection
	▪ Jet grouting	▪ Setback levee
	▪ Relief wells	▪ Vegetation removal
Recreation	▪ Trails	▪ Developed water access
	▪ Riverside parks	▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect would occur in all nine program reaches. The degree of this effect would be greater in the Sacramento River North and South Levee reaches, Port North and South Levee reaches, and the South Cross Levee reach because these reaches support the greatest amount of riparian habitat and associated wildlife species in comparison to the other reaches in the study area.

Effect WILD-4 Finding	With Mitigation
Less than significant	N/A

Section 3.11
Land Use and Agriculture

3.11.1 Introduction

This section describes the regulatory and environmental setting for land use, effects on land use that would result from the program, and mitigation measures that would reduce significant effects.

The key sources of data and information used in the preparation of this section are listed below.

- *City of West Sacramento General Plan* (City of West Sacramento 2004)
- *Yolo County General Plan* (Yolo County 1983)
- *Solano County General Plan* (Solano County 2008)
- California Department of Conservation resource files

3.11.2 Affected Environment

3.11.2.1 Regulatory Setting

3.11.2.1.1 Federal

Farmland Protection Policy Act

A National Agricultural Land Study conducted in the early 1980s found that millions of acres of farmland were being converted to other uses each year in the United States. As a result, a need for Congress to implement programs and policies to protect farmland was identified. Congress then passed the Agriculture and Food Act of 1981, which contained the Farmland Protection Policy Act (FPPA). The purpose of the FPPA is to minimize the extent to which Federal programs contribute to the irreversible conversion of farmland to non-agricultural uses, and to ensure that Federal programs are administered in a manner that will be compatible with state, local, Federal, and private programs and policies to protect farmland. For the purpose of the FPPA, farmland includes prime farmland, unique farmland, and land of statewide or local importance. Farmland subject to FPPA requirements does not have to be used currently for agriculture. These lands may contain forest land, pasture land, cropland, or other land but may not have water or urban built-up land.

Farmland Designations

The purpose of the FMMP farmland designations is to provide consistent and impartial data to decision makers for use in assessing the status, reviewing trends, and planning for the future of agricultural land resources in California; however, the program is not responsible for regulating farmland. FMMP rates agricultural land according to soil quality and irrigation status and updates maps every 2 years. Farmland designations are discussed below.

Prime Farmland

Prime farmland is land that has the best combination of physical and chemical characteristics for producing food, feed, fiber, forage, oilseed, and other agricultural crops with minimum inputs of fuel, fertilizer, pesticides, and labor, and without intolerable soil erosion.

Unique Farmland

Unique farmland is land other than prime farmland that is used for the production of specific high-value food and fiber crops such as, citrus, tree nuts, olives, cranberries, fruits, and vegetables.

Farmland of Statewide Importance

Farmland of statewide importance is land of statewide or local importance identified by state or local agencies for agricultural use, but not of national significance.

3.11.2.1.2 State

Williamson Act

The California Land Conservation Act of 1965, commonly referred to as the Williamson Act, enables local governments to enter into contracts with private landowners for the purpose of restricting specific parcels of land to agricultural or related open space use. In return, landowners receive property tax assessments that are much lower than normal because they are based on farming and open space uses as opposed to full market value. Local governments receive an annual subvention of forgone property tax revenues from the state via the Open Space Subvention Act of 1971.

The Williamson Act was amended in August 1998 to establish Farmland Security Zones. Under this Farm Bureau–sponsored Super Williamson Act, landowners can receive an additional 35% reduction in the land's value for property tax purposes. This additional tax reduction can be earned only if farmers and ranchers keep their property in the conservation program for at least 20 years. Farmland Security Zone contracts are comparable to the Williamson Act contracts in that each year another year is added to the agreement unless the landowner or county does not renew the contract. The legislation prohibits the annexation of land enrolled in a 20-year contract to a city, or a special district that provides non-agricultural services, or for use as a public school site.

Of California's 58 counties, 52 have adopted the Williamson Act program. Yolo County is included in those that have adopted the act. The location of these lands in the project vicinity is discussed in the Environmental Setting that follows.

3.11.2.1.3 Local

Yolo County General Plan

The *Yolo County General Plan* defines land use and zoning goals and policies for the county. The following program-related policies are included in the general plan.

Goals

- **AG-1:** Conserve and preserve agricultural lands in Yolo County, especially areas currently farmed or having prime agricultural soils and outside existing planned communities and city limits.

- **AG-3:** Ensure the compatibility of land uses adjacent to agricultural operations, so that agricultural productivity is not substantially affected.
- **AG-6:** Provide opportunities for recreation, tourism and associated support services in appropriate locations.

Policies

- **AP-1:** Land uses in areas designated for agricultural use shall be limited to those directly related to agricultural production or support of agriculture.
- **AP-2:** The County shall utilize an Agricultural Conservation Easement Program to help protect and preserve agricultural lands, as defined in this Element. This program shall require payment of an in-lieu fee sufficient to purchase a farmland conservation easement, farmland deed restriction, or other farmland conservation mechanism as a condition of approval for conversion of agricultural land to non-agricultural use. The in–lieu fee or other conservation mechanism shall recognize the importance of land value and shall require equivalent mitigation. This may include the use of a variable standard that requires a commitment to preserve fewer acres if the land to be preserved is threatened by development and a greater number of acres to be preserved if the land to be preserved is removed from development pressures.
- **AP-5:** Yolo County shall actively maintain the Williamson Act Land Conservation (Agricultural Preserve) program.

Solano County General Plan

The *Solano County General Plan* defines land use and zoning categories for the county. The following program-related policies and goals are included in the general plan.

Goals

- **LU.G-4:** Encourage land use development patterns and circulation and transportation systems that promote health and wellness and minimize adverse effects on agriculture and natural resources, energy consumption, and air quality.
- **AR.G-1:** Recognize, value, and support the critical roles of all agricultural lands in the stability and economic well-being of the county.
- **AR.G-2**: Preserve and protect the county's agricultural lands as irreplaceable resources for present and future generations.

Policies

- **LU.P-3:** The designation of specific lands and water bodies as "Agriculture", "Watershed", "Marsh", "Park & Recreation", or "Water Bodies & Courses" on the Solano County Land Use Diagram, adopted by the Solano County Board of Supervisors on December 19, 1980, and as amended subsequently consistent with Proposition A, and the Orderly Growth Initiative, shall remain in effect until December 31, 2028 except lands designated Agriculture may be re-designated pursuant to the procedure specified in Agricultural Policies AG.P-32 through AG.P-36 (providing for re-designation upon the making of specific findings, or as necessary to comply with state law requirements regarding provision of low and very low income housing, or permitting certain re-designations to open space).

In addition, these agricultural and open space lands may also be re-designated after a final judgment by a court of competent jurisdiction determining that the absence of a re-designation would constitute an unauthorized taking of private property or is otherwise unconstitutional, but only to the minimum geographical extent and intensity of use necessary to avoid such unconstitutional result. Any such re-designation shall be designed to carry out the goals and provisions of this policy to the maximum extent possible.

Further, the precise boundaries of land use designations may be subject to minor adjustment and refinement prior to development, or upon request of an affected landowner, provided such refinements reflect the overall boundaries indicated on the general plan land use diagram and are consistent with all other general plan policies, in particular, the general plan policies prohibiting piecemeal conversions of agricultural lands to non-agricultural uses.

- **LU.P-32:** Implement land use designations through a compatible zoning ordinance.
- **LU.P-34:** Promote patterns of development that encourage physical activity to reduce obesity, cardiovascular disease, asthma, diabetes, or injury; and that contribute to a "sense of place" and emotional well-being.
- **AG.P-4:** Require farmland conversion mitigation for either of the following actions:
  a. A General Plan amendment that changes the designation of any land from an agricultural to a non-agricultural use; or
  b. An application for a development permit that changes the use of land from production agriculture to a non-agricultural use, regardless of the General Plan designation.

City of West Sacramento General Plan

Land use and development in the study area are guided primarily by the *City of West Sacramento General Plan*. The general plan defines land use and zoning categories for the incorporated areas and provides an inventory of existing land uses in the city. The following policies and goals are included in the general plan.

Natural Resources

- **Goal B:** To promote the economic viability of agriculture in West Sacramento and to discourage premature development of agricultural land with non-agricultural uses, while providing for urban needs.
- **Policy 3:** The City shall encourage the County of Yolo to retain agricultural uses on lands adjacent to the city.

The general plan also includes land use standards for zoning purposes. The following program-related land use designations include public/quasi-public as a possible use: rural residential, residential, commercial/water-related, heavy industrial, industrial/water-related, waterfront, public/quasi-public, recreation and parks, and agriculture.

Delta Protection Commission

The Delta Protection Act of 1992 created the Delta Protection Commission. The Commission seeks to adaptively protect, maintain, and wherever possible, enhance and restore the overall quality of the Delta environment consistent with the Delta Protection Act. The Commission's goal is to guide

orderly, balanced conservation and development of land resources in the Delta, and to improve flood protection.

The Commission divided the Delta area into a primary zone and a secondary zone. The city of West Sacramento is in the secondary zone, and parts of the Yolo Bypass are in the primary zone. Within the primary zone, standards limit uses and practices that could affect the beneficial uses of the Delta. Local county general plans all designate the primary zone primarily for agriculture; however, recreation, wildlife habitat, and nature preserves are approved on agriculture-zoned lands.

The secondary zone of the Delta surrounds the primary zone. The area of the city that lies south of the main line is within the secondary zone. While no standards affect the secondary zone, development within these areas is coordinated with and monitored by the Commission.

3.11.2.2 Environmental Setting

This section discusses the existing conditions related to land use and agriculture in the study area.

West Sacramento lies in eastern Yolo County between the Sacramento River on the east and the east levee of the Yolo Bypass on the west. It lies directly across the Sacramento River from downtown Sacramento and is approximately 85 miles east of San Francisco. The city of West Sacramento comprises approximately 14,912 acres (23.3 square miles) and is a mix of residential, agricultural, industrial, open space, and commercial lands.

Yolo County has a long history of agricultural production, and the California Department of Conservation inventoried 390,250 acres of designated important farmland in the county in 2006, out of a total county area of 653,451 acres. Of these, 257,893 acres were designated as prime farmland, 16,989 acres as farmland of statewide importance, 50,197 acres as unique farmland, and 43,213 acres as farmland of local importance (California Department of Conservation 2008b).

3.11.2.2.1 Levee Reach Land Use

A description of the land use associated with each levee reach in the study area is presented below. Figures 3.11-1 and 3.11-2 present the City of West Sacramento zoning map and the City of West Sacramento important farmland map, respectively.

Sacramento River North Levee

The Sacramento River North Levee is located on the northern and northeastern sides of the city of West Sacramento, along the Sacramento River. Land uses along the levee are diverse and include the following zoning designations: agricultural, public open space, multiple family residential, single family residential, recreation/parks, public/quasi public, and waterfront. These lands include the Bryte Bend Water Treatment Plant, Bryte Park, Riverbank Elementary School, Bryte Elementary School, Yolo County Park, the City of West Sacramento Department of Public Works and the CHP Academy. This reach contains no lands that are listed by the Farmland Mapping and Monitoring Program (FMMP) as important farmland. A small strip of land at the northern terminus of the levee has been designated by the City as agricultural; however, it is not considered important farmland by FMMP (California Department of Conservation 2008b).

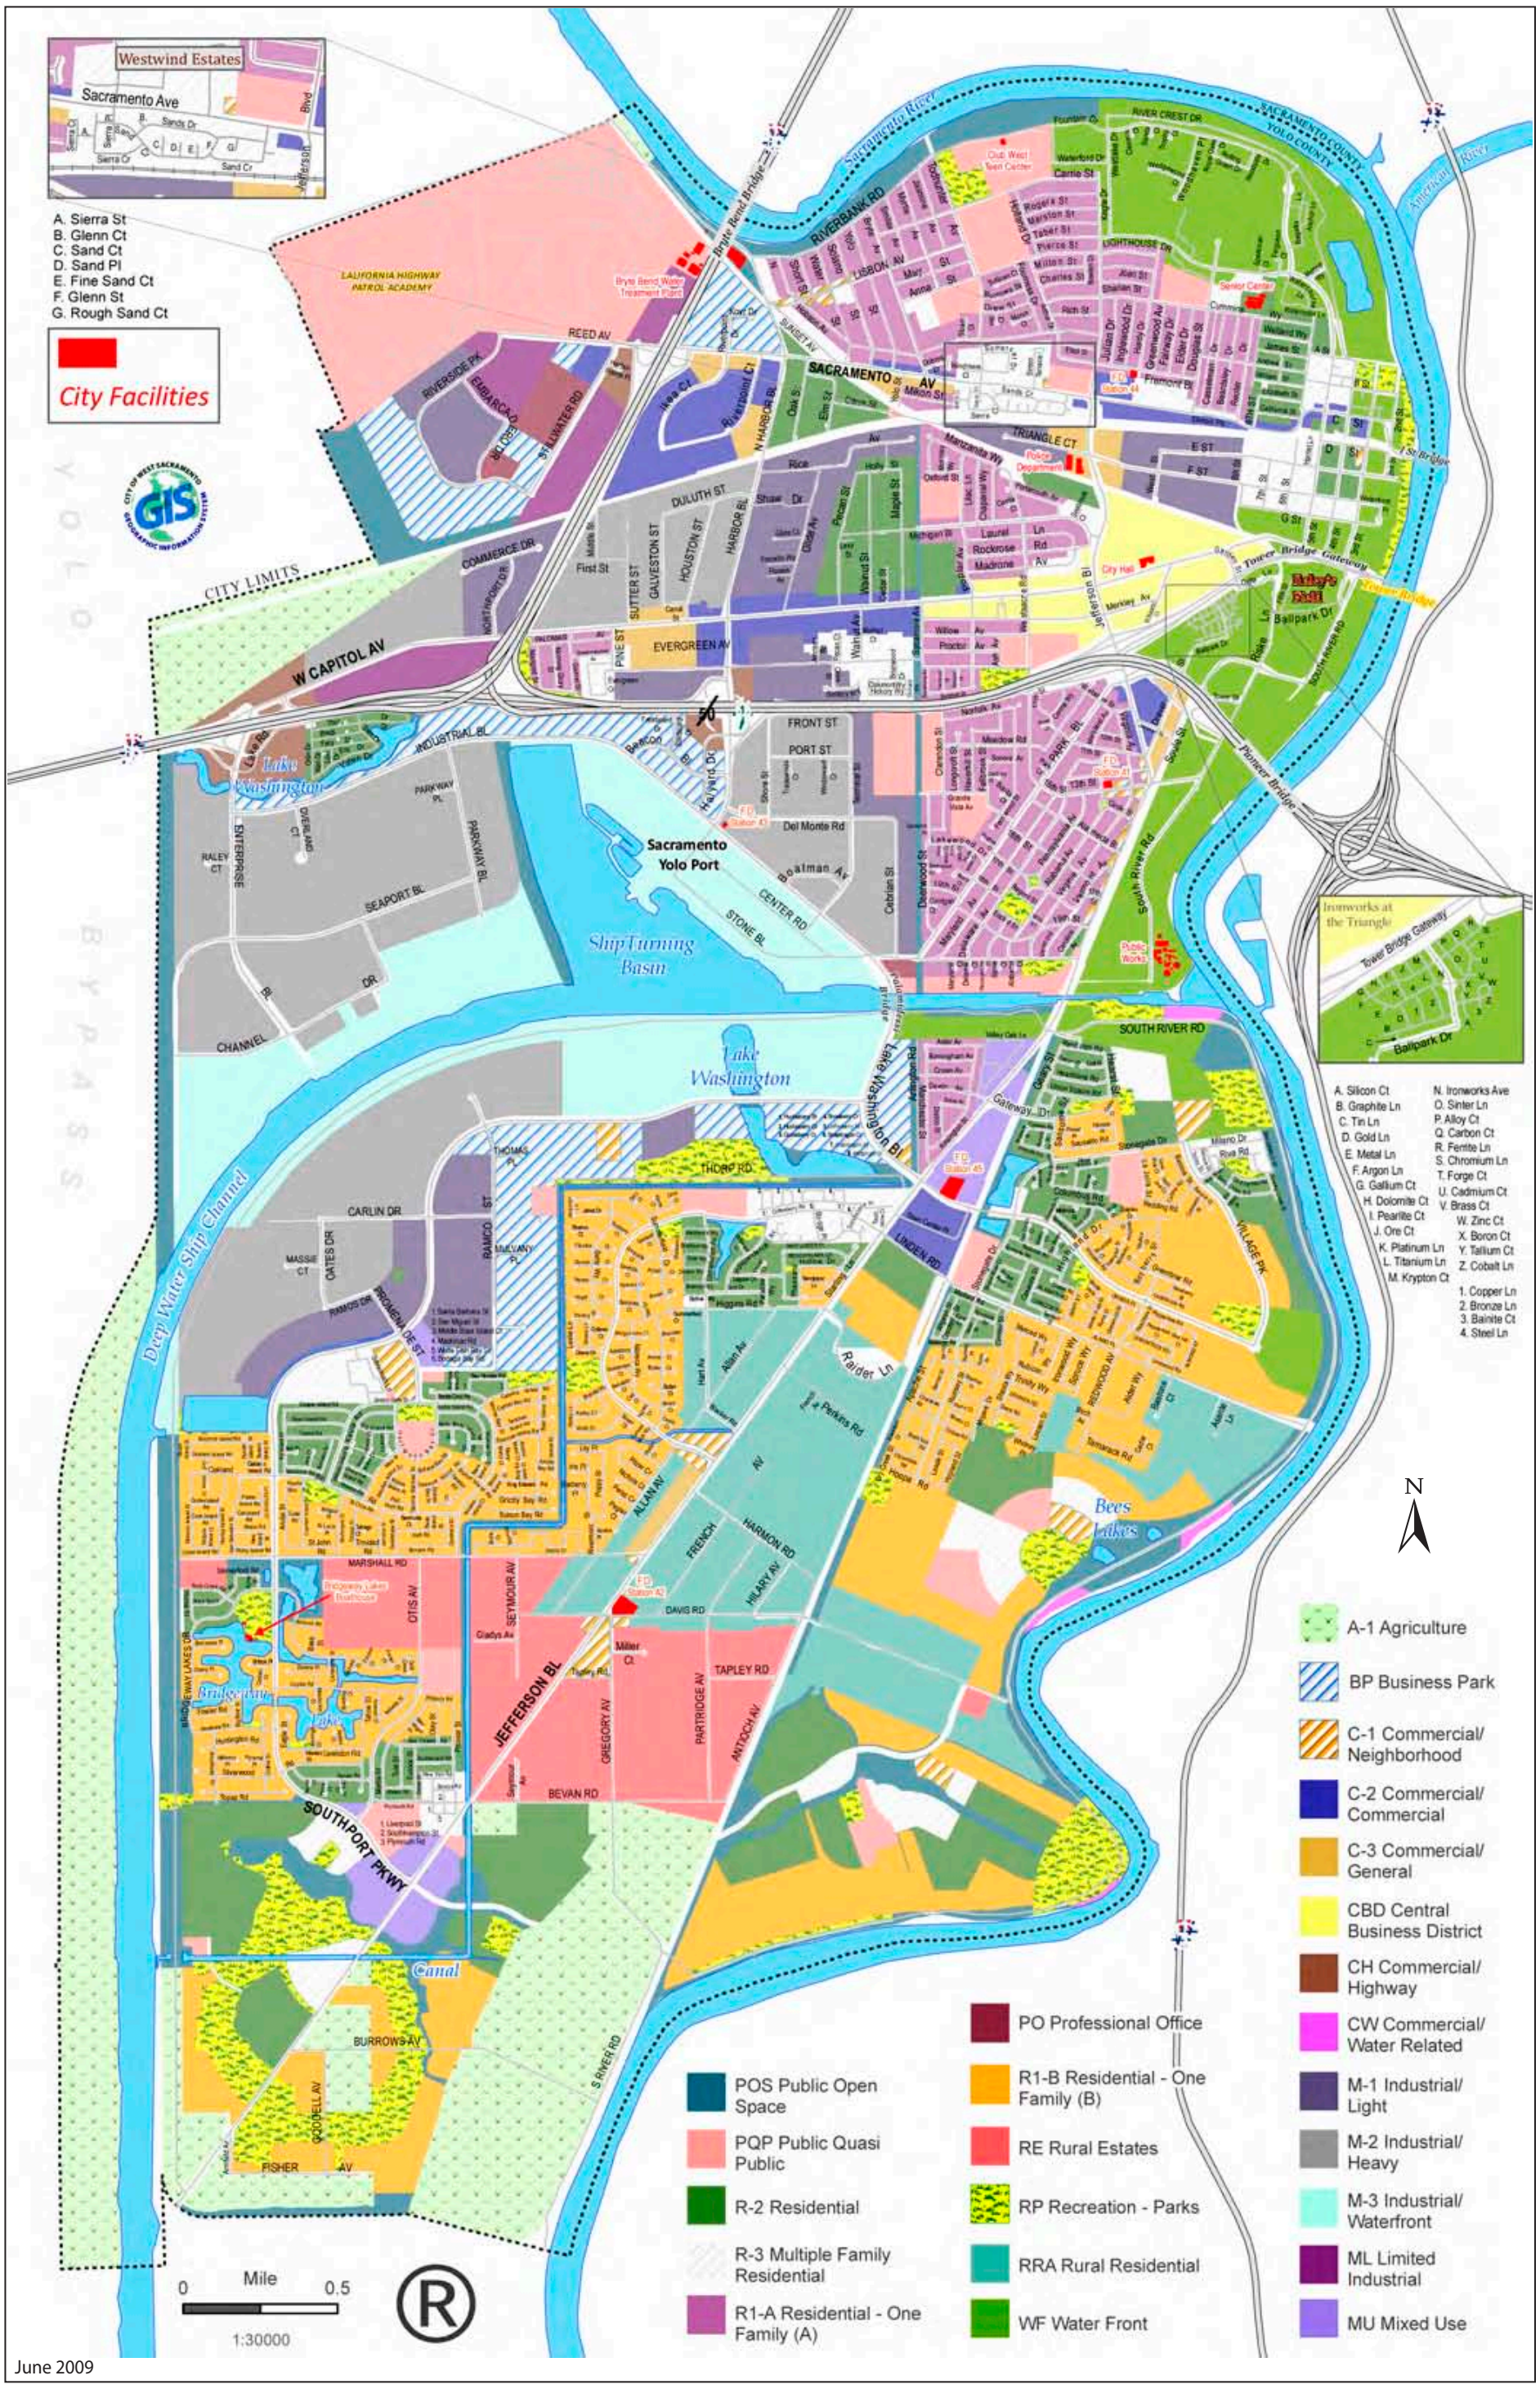
Sacramento River South Levee

The Sacramento River South Levee is located in the southeastern portion of the city of West Sacramento, along the Sacramento River. Land uses along the levee are primarily public open space, residential, single family residential, and rural residential. The area is largely undeveloped; however, recreation/parks, waterfront, agricultural, and commercial water-related uses occur along the levee. The agricultural lands are located adjacent to the southern end of the levee. FMMP has designated several areas within 500 feet of the Sacramento River South Levee as prime farmland, totaling 175 acres. Large sections of this prime farmland acreage lie between Linden Road and Davis Road, and a section runs from Oak Hall Bend to the South Cross Levee (California Department of Conservation 2008b).

Port North Levee

The Port North Levee extends from the western side of the city to the eastern side, running along the northern bank of the northern extent of the DWSC, the Port of West Sacramento, and the barge canal. Land uses adjacent to the levee are primarily industrial-waterfront, although public open space, industrial-heavy, public-quasi public, business park, residential, and waterfront zones are also located adjacent to the levee. Most of the development along this reach is related to the Port of West Sacramento. The residential zone is located near the portion of the levee that runs between Industrial Boulevard and Jefferson Boulevard. This reach contains no lands that are listed by FMMP as important farmland (California Department of Conservation 2008b).

Port South Levee

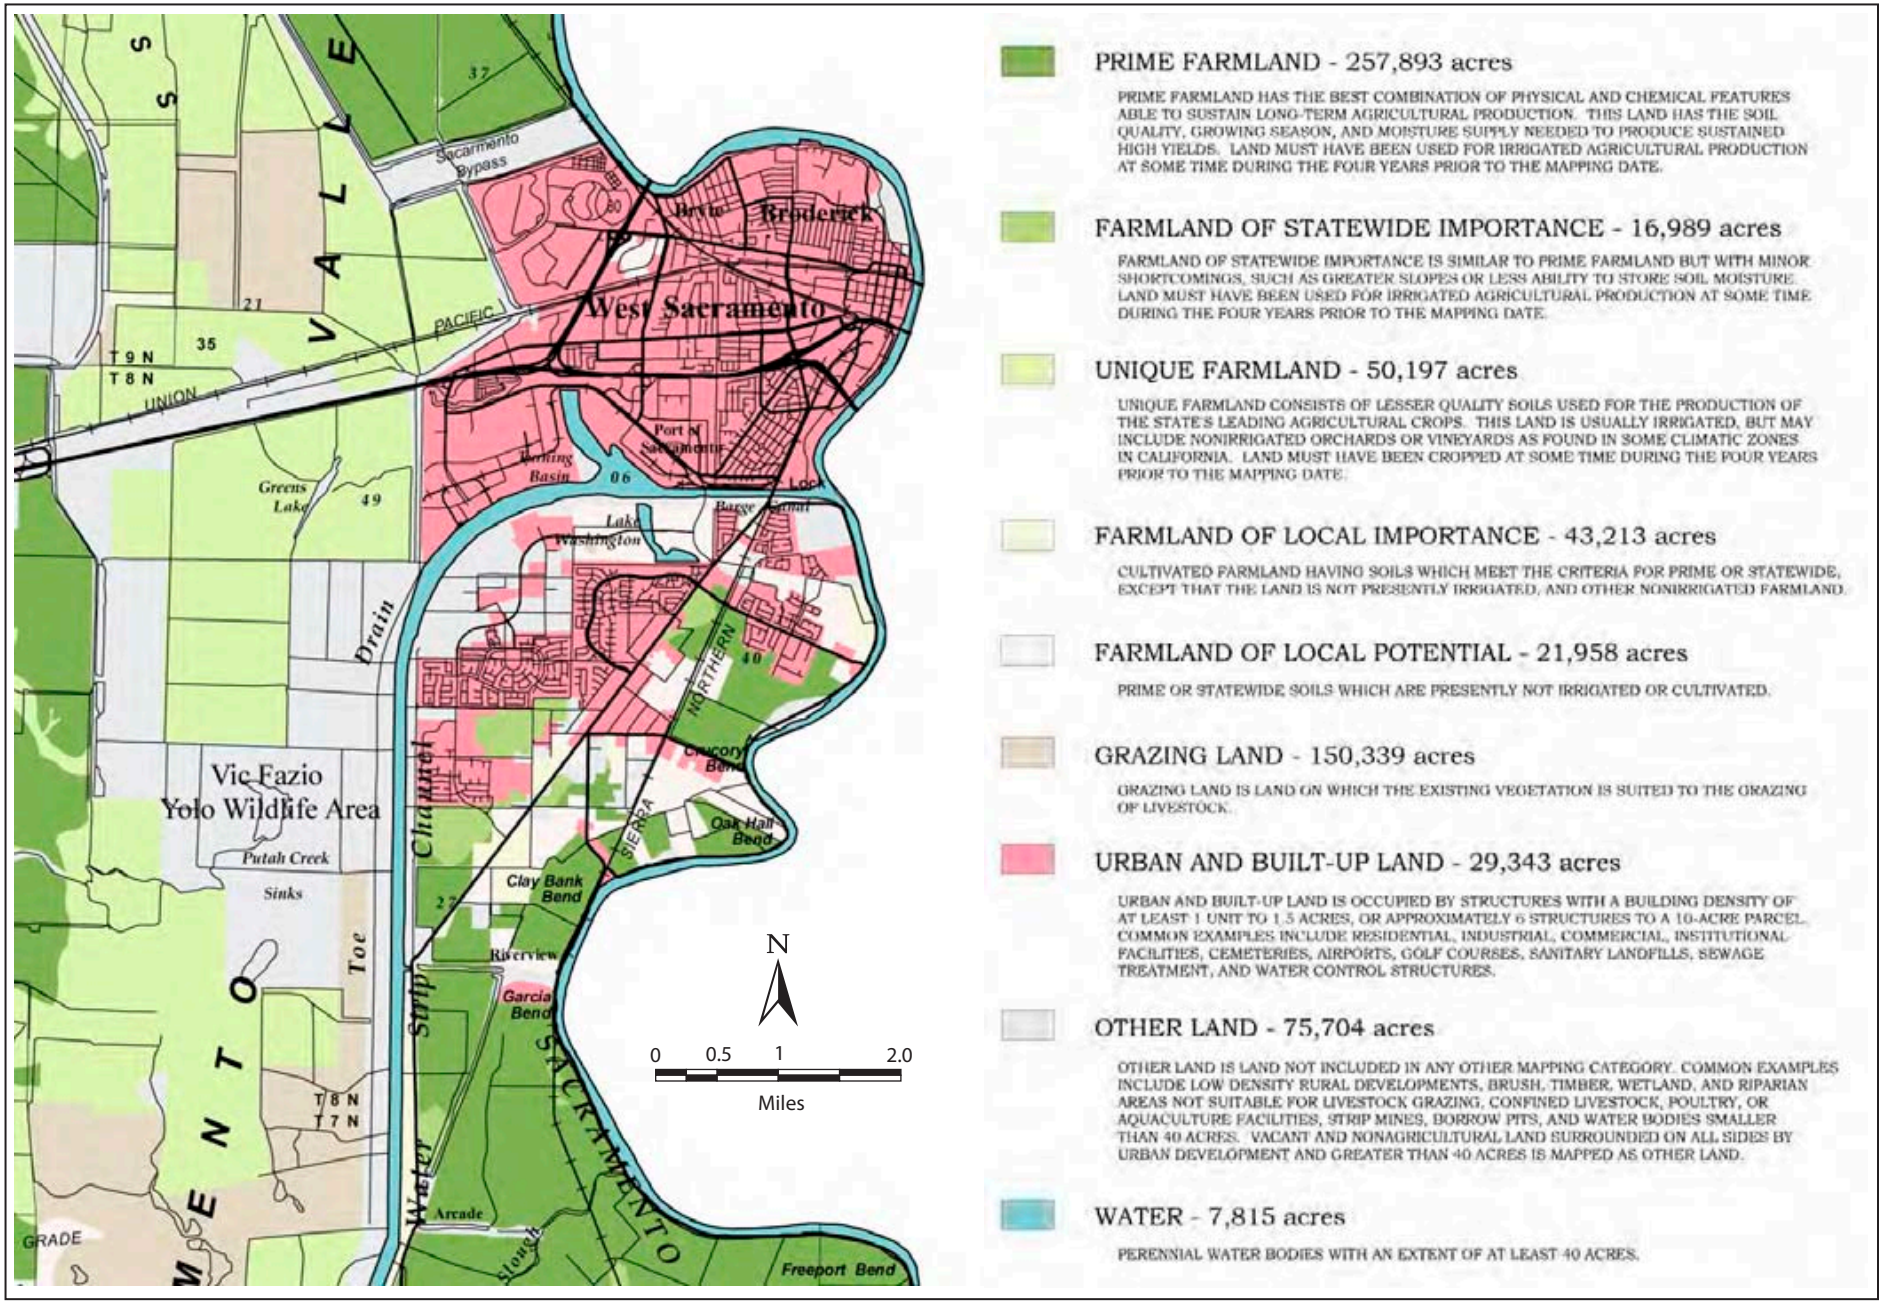


The Port South Levee extends from the western side of the city to the eastern side, running along the southern bank of the DWSC and the barge canal. Land uses adjacent to the levee are primarily industrial-waterfront, although public open space, industrial-heavy, waterfront, recreation/parks, and commercial water-related zones are also located adjacent to the levee. The lands in this reach are largely undeveloped, with the exception of a residential neighborhood located between Jefferson Boulevard and Lake Washington Boulevard, south of the barge canal. Access to the Barge Canal Recreation Area is also located along the Port South Levee. This reach contains no lands that are listed by the FMMP as important farmland (California Department of Conservation 2008b).

South Cross Levee

The South Cross Levee constitutes the southern edge of the city limits for West Sacramento, and runs east to west from the DWSC to the Sacramento River. Land uses adjacent to the levee are designated almost entirely as agricultural, although there is a small strip designated as public open space that runs along the western half of the levee. The area adjacent to the levee is undeveloped, with the exception of a few agriculture-related buildings and residences. This reach contains 29 acres of FMMP designated prime farmland within 500 feet of the north side of the levee. Additionally, 36 acres of prime farmland and 5 acres of farmland of statewide importance are within 500 feet of the south side of the levee (California Department of Conservation 2008b).

DWSC West Levee



The DWSC West Levee runs north to south along the western border of the DWSC. The levee begins just southwest of the Port of West Sacramento and continues south to Liberty Island in the Delta.

00875.07 EIR (8-09)

June 2009

Figure 3.11-1
City of West Sacramento Zoning Map

00875.07 EIR (8-09)

Figure 3.11-2
City of West Sacramento Important Farmland

The only lands adjacent to the levee that lie within the city limits of West Sacramento are located along the northernmost 3 miles of the levee and are zoned as agricultural lands by the City.

Lands south of the city limits that are adjacent to the levee are part of Yolo and Solano Counties and consist primarily of the Yolo Bypass. Lands within the Yolo Bypass in Yolo County are designated as open space, with the exception of a tract of land that is under Williamson Act contract. Open space lands include The Vic Fazio Yolo Wildlife Area (southwestern corner of the West Sacramento city limits) and The North Central Valley Wildlife Management Area (south of the city of West Sacramento). The reach contains lands that have been designated by FMMP as farmland of local importance along various portions of the levee (California Department of Conservation 2008b). Williamson Act lands are located near the levee at the southwestern corner of the city limits; however, these lands are located outside the area of potential direct effect for the program.

Lands within this reach that fall within Solano County are designated as agricultural (Solano County 2008). However, there are no FMMP lands designated as important farmland along the portion of the levee that is located in Solano County (California Department of Conservation 2008a).

This reach also has land that is located within the primary zone of the Delta, as designated by the Delta Protection Commission.

DWSC East Levee

The DWSC East Levee runs from near the north end of the DWSC to the southern edge of the city limits, along the eastern bank of the DWSC, which is on the western edge of the city. Land uses adjacent to the levee are designated as public open space, public-quasi public, residential, single family residential, rural estates, and recreation/parks, with agricultural land located along the southern portion of the levee. The residential areas are located adjacent to the northern half of the levee. This reach contains no lands that are listed by the FMMP as important farmland (California Department of Conservation 2008b).

Yolo Bypass Levee

The Yolo Bypass Levee is located along the Yolo Bypass on the northwestern edge of the city. Land uses adjacent to the levee are designated by the City primarily as public open space, industrial-heavy, and agricultural. There are also some areas zoned as business park, industrial-water front, commercial-highway, and public/quasi-public. The CHP Academy is located adjacent to the northern section of the levee. The land designated by the City as agricultural is located on the western side of the levee. The industrial areas are located along the southern portion of the levee, near the Port of West Sacramento and the DWSC. The reach contains 4 acres of land that has been designated by FMMP as unique farmland along the western side of the levee, outside the city limits of West Sacramento (California Department of Conservation 2008b).

Sacramento Bypass Levee

The Sacramento Bypass Levee is located along the northern city limits on the southern edge of the Sacramento Bypass. Land adjacent to the levee consists of the CHP Academy, designated entirely as public/quasi-public. The CHP Academy consists of a driving course, associated structures, firing range, and open space. The reach does not contain lands designated by FMMP as important farmland (California Department of Conservation 2008b).

3.11.3 Environmental Consequences

This section describes the potential effects on land use and agriculture from implementation of the proposed program. It describes the assessment methods used to determine the effects of the program and lists the thresholds used to conclude whether an effect would be significant. Measures to mitigate (i.e., avoid, minimize, rectify, reduce, eliminate, or compensate for) these significant effects accompany each discussion.

3.11.3.1 Assessment Methods

Effects on land use and agriculture were evaluated based on a review of the regulatory setting above, review of the program in regard to compliance with Federal, state and local land use plans and regulations, and field observations.

3.11.3.2 Determination of Effects

For this analysis, an effect pertaining to land use and agriculture was considered significant if it would result in any of the following environmental effects, which are based on professional practice and State CEQA Guidelines Appendix G (14 CCR 15000 *et seq*.).

3.11.3.2.1 Land Use

For the purposes of this analysis, effects on land use are considered significant if implementation of the proposed program would:

- physically divide an established community;
- conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the project adopted for the purpose of avoiding or mitigating an environmental effect; or
- conflict with any applicable habitat conservation plan or natural community conservation plan.

3.11.3.2.2 Agriculture

For the purposes of this analysis, effects on agriculture are considered significant if implementation of the proposed program would:

- convert prime farmland, unique farmland, or farmland of statewide importance;
- conflict with existing zoning for agricultural use, or a Williamson Act contract; or
- involve other changes in the existing environment, which because of their location or nature, could result in conversion of farmland to non-agricultural use.

The program would be considered to have a significant effect on important farmland (i.e., prime farmland, unique farmland, farmland of statewide importance) if it would result in an irretrievable conversion of a substantial acreage of such land. An irretrievable conversion is one that involves the conversion of land to uses that would cause serious degradation of the quality of soils and/or result in expenditures of substantial development costs that likely would preclude the practicality of future conversion back to agriculture. Implementation of the program would not physically divide an established community. There would be no conflict with any applicable habitat conservation plan or natural community conservation plan, as none covers areas located within the study area.

Additionally, there would be no conflict with a Williamson Act contract because no Williamson Act lands are located within the study area. Therefore, the first, third, and fifth criteria do not apply to the program and are not considered further.

3.11.3.3 Effects and Mitigation Measures

3.11.3.3.1 No Action Alternative

To recap from Chapter 2, Alternatives, the No Action Alternative is the continuation of the existing deficiencies along the nine levee reaches and absence of levee alternatives to increase the level of protection. Current levee operations and maintenance activities would continue. Without implementation of the program, there would be no changes to zoning designations in the city of West Sacramento, and there would be no intentional conversion of Williamson Act, important farmland, or other agricultural land to an incompatible use.

Given levee conditions, the risk of levee failure would continue under the No Action Alternative. A flood event could have severe ramifications for agriculture and land use in West Sacramento. Flooding may cause inundation, erosion or sedimentation from high flows, destruction or damage to agricultural equipment, outbuildings and processing facilities, all of which could lead to reduction in agricultural productivity. This damage may cause depression of the agricultural economy and cause abandonment of or prolonged delay in cultivation of productive lands, which could ultimately result in a change in the use of these lands that may be difficult to reverse.

Similarly, levee failure could significantly change the land uses in urban areas, both temporarily and permanently, and result in the physical division of established communities. A period of months or years would be required for clean-up and repair after a large flood event, during which time the affected parcels would be temporarily unable to support their designated land uses. Damages sustained by residential, commercial, civic, and industrial areas inundated by flooding could be so great as to render the properties permanently unusable. Additionally, the cost of cleanup and repair after flooding could be too great to make restoring the current land use worthwhile, resulting in permanent changes to land use in West Sacramento and potential division of established communities.

3.11.3.3.2 Flood and Recreation Program Alternatives

Effect LU-1: Temporary Changes in Land Uses to Accommodate Construction

During levee alternative and recreational element construction, a staging area to house offices, stockpiling areas to store soils, and staging areas to park equipment such as bulldozers, compactors, drill rigs, and excavators would be necessary. Temporary construction roads and ramps also could be built on site at specific project sites. Lands used for construction staging and stockpiling would be agricultural, vacant or undeveloped, and these lands would be returned to their original use following the completion of construction. If agricultural lands are required for long-term temporary staging and construction activities, these lands would likely represent only a small fraction of the total agricultural lands within Yolo or Solano County and production of these lands would resume after construction activities are complete. Thus, the proposed program would not result in significant effects on land use as a result of temporary land use changes. This effect is considered less than significant. No mitigation is required. Refer to Section 3.12, Socioeconomics and

Community Effects, for a discussion of effects related to compensation of agriculture-related income for temporary loss of use of farmlands.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall ▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Closure structure ▪ Interior drain ▪ Jet grouting ▪ Relief wells	▪ Seepage berm ▪ Sheet pile wall ▪ Slurry cutoff wall ▪ Slope flattening ▪ Stability berm ▪ Rock slope protection ▪ Setback levee ▪ Vegetation removal
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

Effect LU-1 would occur in all nine reaches. Temporary staging areas would be required for all of the flood and recreation alternatives.

Effect LU-1 Finding	With Mitigation
Less than significant	N/A

Effect LU-2: Change in Land Use Designations or Potential to Conflict with Land Use Designations as a Result of Construction

Implementation of levee alternatives that would extend the levee footprint landward could result in a change of land use designation to levee or levee access routes. However, the program proponent would follow a selection process for levee alternatives that would take into account criteria such as the need to purchase real estate and land use compatibility, among others. In some cases, the most appropriate treatment may require acquisition and a change in land use designation to a minimal amount of land within the city of West Sacramento or Yolo or Solano County to enable the construction and continued operation of levee alternatives. Nonetheless, the amount of change is not likely to result in the conversion or change of a substantial amount of any land use designation within the study area.

With the exception of the recreation trail on the South Cross Levee, program recreation alternatives would take place in areas that allow for public/quasi-public use and would have no effect on land use. The proposed South Cross Levee recreation trail would be constructed on land that is currently under private ownership. However, this re-designation of private land to public use is planned for in City of West Sacramento's Parks Master Plan and therefore would not conflict with existing land use plans. Therefore, these effects are considered less than significant. No mitigation is required.

Refer to Section 3.12, Socioeconomics and Community Effects, for a discussion of effects related to compensation for loss of lands or loss of agriculture-related income resulting from permanent loss of use of farmlands.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Levee raise (adjacent)	▪ Slope flattening
	▪ Levee raise (full)	▪ Stability berm
	▪ Seepage berm	▪ Setback levee

Affected Reaches

Effect LU-2 would occur in the Sacramento River North, Sacramento River South, Port South, South Cross, DWSC West, DWSC East, Yolo Bypass, and Sacramento Bypass Levee reaches. These reaches all have levee treatment options that could result in an increase in the levee footprint.

Effect LU-2 Finding	With Mitigation
Less than significant	N/A

Effect LU-3: Important Farmland Converted to Non-Agricultural Uses

It is anticipated that several staging areas and temporary-access haul roads would be developed on agricultural lands in the study area during program construction. Land at construction staging areas and haul roads classified as important farmland could be temporarily taken out of production for the duration of the construction period to accommodate pre-construction and construction activities. These areas would be returned to pre-program conditions, and agricultural uses could resume once construction is completed. Therefore, there would be no direct conversion of important farmland to non-agricultural uses in construction staging areas.

However, certain reaches of the study area are located adjacent to important farmland, as designated by the FMMP. Implementation of several program treatments (e.g., setback levees, adjacent levee raises, slope flattening) would result in a relatively small permanent loss of important farmland acreage in the city of West Sacramento, with the loss occurring in the area immediately adjacent to the levee reaches. These types of treatments would result in the conversion of important farmland to an incompatible use, with a setback levee converting the most land—111 acres. This acreage accounts for approximately 0.0284% of the 390,250 acres of important farmland in Yolo County. Compared to the amount of important farmland that still would be available for agricultural production, the amount converted by the program would be negligible. Additionally, implementation of recreational elements of the program would not result in the conversion of any important farmland. Therefore, this effect is considered less than significant. No mitigation is required.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Levee raise (adjacent) ▪ Levee raise (full)	▪ Slope flattening ▪ Stability berm ▪ Setback levee

Affected Reaches

Effect LU-3 would occur in the South Cross, DWSC East, and Sacramento River South Levee reaches. Agricultural land within the city limits is confined to the southern portion of the city.

Effect LU-3 Finding	With Mitigation
Less than significant	N/A

Section 3.12

Socioeconomic and Community Effects

3.12.1 Introduction

This section describes the regulatory and environmental setting for socioeconomic conditions, including employment, agricultural production, population, and housing; the effects on socioeconomic and community conditions that would result from the program, and mitigation measures that would reduce significant effects.

The key sources of data and information used in the preparation of this section are listed below.

- California Department of Finance City/County Population and Housing Estimates (California Department of Finance 2009a, 2009b, 2009c)
- California Department of Water Resources Land Use Survey (California Department of Water Resources 1997)
- California Employment Development Department El Dorado, Placer, Sacramento, Sutter, Yolo, Yuba, and Solano County Local Area Profiles (California Employment Development Department 2009a, b, c, d, e, f, and g)
- *City of West Sacramento General Plan Policy Document* (City of West Sacramento 2004)
- *City of West Sacramento General Plan Background Document* (City of West Sacramento 2000)
- *Solano County Department of Agriculture 2008 Crop and Livestock Report* (Solano County Department of Agriculture 2008)
- U.S. Census Bureau QuickFacts (U.S. Census Bureau 2009a, 2009b, 2009c)
- *Yolo County 2008 Agricultural Crop Report* (Yolo County Department of Agriculture 2008)

3.12.2.1 Regulatory Setting

3.12.2.1.1 Federal

Uniform Relocation Assistance and Real Property Acquisition Policies Act

Federal, state, and local government agencies, and other agencies receiving Federal financial assistance for public programs and projects that require the acquisition of real property, must comply with the policies and provisions set forth in the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, as amended in 1987 (42 USC 4601 *et seq*.) (Uniform Act), and implementing regulation, Title 49 CFR Part 24. Relocation advisory services, moving cost reimbursement, replacement housing, and reimbursement for related expenses and rights of appeal are provided for in the Uniform Act.

Property acquisition and relocation services, compensation for living expenses for temporarily relocated residents, and negotiations regarding any compensation for temporary loss of business would be accomplished in accordance with the Uniform Act and California Government Code Section 7267, *et seq*. (see discussion below).

3.12.2.1.2 State

Relocation Assistance and Property Acquisition

The State of California's Government Code Section 7260, *et seq*. brings the California Relocation Act into conformity with the Federal Uniform Act. In the acquisition of real property by a public agency, both the Federal and state acts seek to (1) ensure consistent and fair treatment of owners of real property, (2) encourage and expedite acquisition by agreement to avoid litigation and relieve congestion in the courts, and (3) promote confidence in public land acquisition.

The Relocation Assistance and Real Property Acquisition Guidelines were established by 25 CCR 1.6. The guidelines were developed to assist public entities with developing regulations and procedures for implementing 42 USC 61—the Uniform Act, for Federal and federally assisted programs. The guidelines are designed to ensure that uniform, fair, and equitable treatment is given to people displaced from their homes, businesses, or farms as a result of the actions of a public entity. Under the Uniform Act, persons required to relocate temporarily are not considered "displaced," but must be reimbursed for all reasonable out-of-pocket expenses. In accordance with these guidelines, people will not suffer disproportionate injury as a result of action taken for the benefit of the public as a whole. Additionally, public entities must ensure consistent and fair treatment of owners of such property, and encourage and expedite acquisitions by agreement with owners of displaced property to avoid litigation.

Property acquisition and relocation services, compensation for living expenses for temporarily relocated residents, and negotiations regarding any compensation for temporary loss of business would be accomplished in accordance with the Uniform Act (see discussion above) and California Government Code Section 7267, *et seq*.

General Plans

State law requires each city and county to adopt a general plan for its future growth. This plan must include a housing element that identifies housing needs for all economic segments and provides opportunities for housing development to meet those needs. At the state level, the Housing and Community Development Department estimates the relative share of California's projected population growth that will occur in each county presented by the Department of Finance's demographic research unit.

Each city and county must update its general plan housing element on a regular basis (usually every 5 years). Among other things, the housing element must incorporate policies and identify potential sites that would accommodate the city's and county's share of the regional housing need. Prior to adopting a general plan update for housing, the city or county must submit the draft to the Housing and Community Development Department for its review. The Housing and Community Development Department will take action to advise the local jurisdiction whether its housing element complies with provisions of California Housing Element Law. The *City of West Sacramento General Plan Housing Element* was last updated in 1992, but is currently undergoing an update process.

3.12.2.1.3 Local

City of West Sacramento General Plan

The *City of West Sacramento General Plan* was adopted by the City in 1990. Although the 1990 general plan contains policies related to housing and economics, these policies are out of date in light of the significant amount of development that has occurred over the past 20 years. The City is in the process of updating the general plan, which is expected to be complete in 2009. The new general plan will guide the city's growth through 2030. The *General Plan Issues and Opportunities Report*, published in June 2008, identified the following areas of focus related to housing and economics:

- designating higher densities at appropriate locations to support transit,
- promoting mixed-use development,
- maintaining rural residential land in the southern area,
- promoting tourism,
- increasing the number of good-paying jobs (especially in Southport), and
- addressing telecommunication infrastructure.

3.12.2.2 Environmental Setting

3.12.2.2.1 Sacramento Region

Employment

Much of the WSLIP study area is considered part of the greater Sacramento metropolitan region. The Sacramento Area Council of Governments defines the Sacramento metropolitan region as the area encompassing El Dorado, Placer, Sacramento, Sutter, Yolo and Yuba counties. The Sacramento region's economy is broadly based. Government and transportation are the largest sectors of employment in the area. Agriculture and mining—which were historically huge drivers of the Sacramento region's economy—are still strong contributors, but have been surpassed as leading industries by information, technology service, leisure and hospitality, education and health services, and construction. Total taxable sales for 2007 within the six-county Sacramento region topped $35 billion. (California Employment Development Department 2009a, b, c, d, e, and f.)

Technology-related companies such as Intel and Hewlett-Packard are among the Sacramento area's largest employers; proximity to research centers and a well-educated labor pool have drawn such companies to the area. Sacramento's fastest-growing employment areas include financial activities, professional and business services, and education and health services. The California Employment Development Department estimates that as of August 2009, the total labor force in the Sacramento region was approximately 1,135,200, with a 12.2% unemployment rate. (California Employment Development Department 2009a, b, c, d, e, and f.)

3.12.2.2.2 Yolo County

Employment

With its affordable housing and land and its easy access to highway, rail, water and air transportation, Yolo County has an attractive business climate. The primary business sectors are government; professional and business services; transportation, warehousing, and utilities; and agriculture (LSA Associates, Inc. 2009). The largest employers in the county are the University of California Davis, Cache Creek Casino Resort, the U.S. Postal Service, and the State of California (Yolo County 2009). Total retail taxable sales in the county in 2007 were $3,259,843,000 (California Employment Development Department 2009e).

Yolo County has a population of 200,709 (California Department of Finance 2009a). The labor force is 98,200, with 87,900 people employed and 10,300 unemployed; an unemployment rate of 10.5% (California Employment Development Department 2009e). The median household income is $55,988 and the per capita income is $19,365 (U.S. Census Bureau 2009a).

Agricultural Production

Yolo County has a long agricultural heritage and, as recently as its current general plan update, has historically set policies that preserve agriculture. Almost 99% of the county's unincorporated land (621,224 acres) is designated for agricultural use (Yolo County 2008). The 2008 Yolo County Agricultural Crop Report indicates that Yolo County's total agricultural production in 2008 was $527,330,803. This is an increase of more than 16% over 2007 yields. The top- producing crops were tomatoes, alfalfa, rice, wine grapes, and seed crops (Table 3.12-1). It should be noted that these figures represent crop values only, and do not take into account other agricultural contributions to the economy such as field labor, processing, transport, marketing, and other services. When these factors are also considered, agriculture contributes over $1.5 billion to the Yolo County economy. (Yolo County Department of Agriculture 2008.)

Table 3.12-1. Crop Yields and Values for Top-Producing Crops (and Corn and Grain) in Yolo County, 2008

	Total Tonnage Produced	Value per Ton	Total
Alfalfa	387,896	$189.24	$73,405,515
Corn (field)	44,730	$152.19	$6,807,486
Grain	53,969	$179.11	$9,666,518
Rice	105,104	$521.32	$54,792.829*
Rice, wild	3,415	$1,684.17	$5,751,816
Tomatoes	1,528,882	$68.76	$105,124,614
Wine grapes (black)	17,333	$597.72	$10,360.047
Wine grapes (white)	60,069	$526.83	$31,645,542
Seed crops (total)	24,135	Not available	$31,952,413

Source: Yolo County Department of Agriculture 2008.
* Includes Federal rice payment.

The Sacramento Area Council of Governments envisions that, because of its commitment to agriculture and natural resources, Yolo County will grow at a slower rate compared to the rest of the

region. Local retail and office jobs will expand, while industrial jobs will decline (Sacramento Area Council of Governments 2004).

3.12.2.2.3 West Sacramento

Employment

West Sacramento attracts business with an accessible and cooperative government; access to multi-modal transportation (highway, rail, and port); a regional workforce of over one million people; and low business costs (City of West Sacramento Economic Development 2009). The city's economy is moving from a climate that was historically focused the on the transportation and warehouse sectors toward newer industries such as biotech, green energy, and green technology (Mintier & Associates 2008). West Sacramento had an 89% employment growth rate between 1990 and 1999, which is the third highest growth rate of any city in the Sacramento region (City of West Sacramento Economic Development 2009). The top employers are the United Parcel Service, the U.S. Postal Service, Nor-Cal Beverage, and Raleys/Bel Air. The City is targeting the following industries in its *City of West Sacramento General Plan Update* (Mintier & Associates 2008):

- biotechnology/life sciences,
- clean energy and green technology,
- food processing,
- manufacturing,
- retail, and
- small business.

The City's retail business greatly expanded over the last 4 years with the store openings of IKEA, Wal-Mart, Target, Home Depot, Lowe's, and Nugget Market. West Sacramento now has a higher sales-to-income ratio than surrounding communities and the region as a whole (Mintier & Associates 2008). Table 3.12-2 shows West Sacramento's largest private employers.

The Sacramento Area County of Governments envisions that West Sacramento will be the fastest growing city in the region because of its proximity to Sacramento's urban core and many opportunities for reinvestment. Major job growth will be in the retail and office sectors, with less growth in the industrial sector than in the past. (Sacramento Area Council of Governments 2004.)

Table 3.12-2. West Sacramento's Largest Private Employers

Company Name	
United Parcel Service (UPS)	All Phase Security, Inc.
U.S. Postal Service	Bytheways Manufacturing Inc.
Nor-Cal Beverage	Clark Pacific
Raley's/Bel Air	Hunter Douglas
Fed-Ex Freight West, Inc.	Siemens Healthcare Diagnostics
Xyratex International	KOVR TV 13
C & S Wholesale Grocers	Idexx Veterinary Services
First Health Group Corporation	Capital Coors Company

Company Name	
Wal Mart	Consolidated Procurement Services
Prologix Distribution Services	Farmer's Rice Cooperative
Tony's Fine Foods	IKEA
Citibank	Lowe's
Roadway Express	

The City of West Sacramento has a population of 47,782 (California Department of Finance 2009a) and employs 30,655 people (Sacramento Area Council of Governments 2008a). The unemployment rate is 9.5% (California Employment Development Department 2009e). The median household income is $31,718 and the per capita income is $15,245 (U.S. Census Bureau 2009b).

Agricultural Production

The *City of West Sacramento General Plan* designates two areas within the city as agricultural: the area of Southport generally south of Bevan Road and a small part of the Yolo Bypass at the western edge of the city, immediately north of West Capitol Avenue and south of the Southern Pacific tracks (LSA Associates 2009). These areas, in addition to areas with other general plan designations, are currently used for farming (California Department of Water Resources 1997). A very conservative estimate of currently-farmed acreage located within the program footprint is 570 acres.

According to the most recently available DWR Land Use maps, the majority of the land in West Sacramento currently in agricultural production is planted in corn, grain, and alfalfa (California Department of Water Resources 1997). Alfalfa is the second highest-grossing crop in both Yolo and Solano Counties (Table 3.12-3). Grain and corn crops are much smaller overall producers in both counties (Yolo County Department of Agriculture 2008; Solano County Department of Agriculture 2008).

Table 3.12-3. Annual Yields and Values for Crops Grown in West Sacramento

	Tonnage per Acre	Value per Ton	Value per Acre
Corn (field)	5.51	$152.19	$838.57
Grains	3.21	$179.11	$574.94
Alfalfa	6.84	$189.24	$1,294.40

Source: Yolo County Department of Agriculture 2008.

The Port of West Sacramento is an inland port that has historically served the agricultural industry. In 2005, the City of West Sacramento assumed leadership of the port and has since broadened the port's duties to include green cargo (specialized cargo that enhances the environment) (City of West Sacramento 2009a). There are thousands of jobs associated with the port and related movement of goods via truck, rail, and ship (City of West Sacramento 2009b). Due to increased worldwide demand for rice, the port expects to export about 339,000 metric tons of bagged rice this year—about double its normal capacity (The Cunningham Report 2009). President Obama's proposed 2010 Civil Works budget includes $10 million for widening the DWSC that leads to the port. Deepening the DWSC would almost double the number of fully loaded oceangoing freight ships able to access the Sacramento region (Port of West Sacramento 2009).

Population

The City of West Sacramento is the third largest city in Yolo County and is currently experiencing strong, steady growth (Yolo County 2009). The City incorporated in 1987, combining the former communities of Bryte, Broderick, West Sacramento, and Southport. Southport is home to newer residences and Bryte and Broderick have higher percentages of pre-WWII homes. The U.S. Census reports that the population in West Sacramento was 31,615 in 2000 (U.S. Census Bureau 2009b). According to the California Department of Finance the estimated population of residents in West Sacramento in January 2009 was 47,782, a 1.9% increase over 2008 and 51% increase since 2000 (California Department of Finance 2009c).

As a point of reference for the city, information about population in Yolo County is presented here. Yolo County's population is currently 200,709, an increase of 1.2% over last year (California Department of Finance 2009b), and approximately 17.2% over 2000 (U.S. Census Bureau 2009a). Over 88% of Yolo County's population lives in its four incorporated cities—West Sacramento, Davis, Woodland, and Winters. The remaining 12% live in unincorporated areas of the county (Yolo County 2008).

Housing

As the population of West Sacramento grows, the city's housing stock is growing as well. The California Department of Finance estimates that there are currently approximately18,550 total housing units in the city, which is an increase of approximately 50% over the number of housing units in 2000 (California Department of Finance 2009c; U.S. Census Bureau 2009b). An unofficial vacancy rate estimate for the city in 2009 is 5.5% (Sperling's Best Places 2009).

As a point of reference for the city, information about housing in Yolo County is presented here. The California Department of Finance estimates that there are currently approximately 73,811 housing units in Yolo County, an increase of approximately 20% over 2000 levels (California Department of Finance 2009c; U.S. Census Bureau 2009a).

3.12.2.2.4 Solano County

Employment

Solano County's primary business sectors are health and educational services; arts, recreation, and other services; and retail. The top county employers are Kaiser Permanente, Six Flags Discovery Kingdom, NorthBay Healthcare System, and Alza (Solano County Administrator's Office 2007). Table 3.12-4 shows Solano County's largest employers. Total taxable sales in the county in 2007 were $6,277,832,000 (California Employment Development Department 2009g).

Solano County has a population of 426,729 (California Department of Finance 2009a). The labor force is 213,700, with 190,800 employed people and 22,900 unemployed. The unemployment rate is 10.7%. There are 122,600 total wage and salary jobs. (California Employment Development Department 2009g.) The median household income is $66,575, and the per capita income is $21,731 (U.S. Census Bureau 2009c).

Table 3.12-4. Solano County's Largest Employers

Company Name	Employees
Kaiser Permanente (Vallejo/Vacaville/Fairfield)	3,912
Six Flags Discovery Kingdom (Vallejo)	1,500
NorthBay Healthcare System (Fairfield)	1,480
ALZA Corporation (Vacaville)	1,000
Genentech (Vacaville)	950
Wal-Mart (Vacaville/Fairfield/Dixon)	872
Sutter Solano Medical Center (Vallejo)	674
Westamerica Bancorporation (Fairfield)	542
Valero Refining Company—CA (Benicia)	480
Anheuser-Busch Brewery (Fairfield)	465
Albertson's Distribution Center (Vacaville)	450

CSK Auto Incorporated (Dixon)	400
Jelly Belly Candy Company (Fairfield)	400
TIMEC Company (Vallejo)	400

Source: Solano County Administrator's Office 2007.

Agriculture

Solano County's agricultural production is ranked 27th in the state. Almost 99% of the county's unincorporated land (621,224 acres) is designated for agricultural use. The 2008 Solano County Agricultural Crop and Livestock Report indicates that Solano County's total agricultural production in 2008 was $292,840,200. This is an increase of more than 9% over 2007 yields, and an all-time high for the county. The top-producing crops were nursery crops, alfalfa, and tomatoes (Table 3.12-5). It should be noted that these figures represent crop values only, and do not take into account other agricultural contributions to the economy such as field labor, processing, transport, marketing, and other services. When these factors are also considered, agriculture greatly benefits the Solano County economy. (Solano County Department of Agriculture 2008.)

Table 3.12-5. Annual Yields and Values for Crops Grown in Solano County, 2008

	Tonnage per Acre	Value per Ton	Total
Nursery crops	Not available	Not available	$43,056,300
Alfalfa	212,663	$202	$42,889,900
Tomatoes	417,900	$71.43	$29,850,600

3.12.3 Environmental Consequences

This section describes the analysis of effects relating to socioeconomics for the proposed program. It describes the methods used to determine the effects of the program and lists the thresholds used to conclude whether an effect would be significant. Measures to mitigate (i.e., avoid, minimize, reduce, eliminate, or compensate for) significant effects accompany each effect discussion.

3.12.3.1 Assessment Methods

Potential effects on socioeconomic conditions related to construction and/or operation of the WSLIP are considered at a program level. Effects on socioeconomics related to implementation of the WSLIP were evaluated qualitatively, based on the criteria below. Additionally, the proposed program was evaluated for consistency with relevant local plans and policies at the Federal, state, and local levels.

3.12.3.2 Determination of Effects

For this analysis, an effect pertaining to socioeconomics was considered significant if it would result in any of the following environmental effects, which are based on professional practice and State CEQA Guidelines Appendix G (14 CCR 15000 *et seq*.).

- a substantial change in employment;
- inducement of substantial population growth in an area, either directly (e.g., by proposing new homes and businesses) or indirectly (e.g., through extension of roads or other infrastructure); or
- displacement of substantial numbers of existing housing or people, necessitating the construction of replacement housing elsewhere.

3.12.3.2.1 Effect Assumptions

Several of the alternatives proposed under the program would require land acquisition and may require removal of residences to accommodate the expanded footprint of the levee system. Land acquisition may be necessary for implementation of adjacent levee raises, full levee raises, relief wells, seepage berms, slope flattening, stability berms, and setback levees. In addition, sufficient land would need to be acquired to establish an appropriate maintenance corridor at the landside toes of all improved levees. Acquisition and relocation services, as well as compensation for living expenses for temporarily relocated residents, would be conducted in compliance with Federal and state relocation laws, which are the Uniform Act of 1970 (42 USC 4601 et seq.) and implementing regulation, 49 CFR Part 24; and California Government Code Section 7267 *et seq.* These laws require that appropriate compensation be provided to displaced landowners and tenants, and that residents be relocated to comparable replacement housing. More details regarding these regulations are provided above in the Regulatory Setting section. There is sufficient available housing stock for rent and purchase to accommodate displaced residents from these residences. Therefore, no new construction would be required to achieve the relocation of residents.

3.12.4 Effects and Mitigation Measures

3.12.4.1 No Action Alternative

To recap from Chapter 2, Alternatives, the No Action Alternative is the continuation of the existing deficiencies along the nine levee reaches and absence of levee alternatives to increase the level of protection, resulting in continued or even potentially increased risk of catastrophic flooding of the city. Current levee operations and maintenance activities would continue. No construction-related effects would occur.

Without implementation of the program, there would be no changes in existing population or employment but for the changes currently planned for in the appropriate local and state planning documents. No displacement of existing residences to accommodate an expanded levee footprint for certain levee alternatives would occur. However, the risk of levee failure would continue.

3.12.4.1.1 Consequences of Levee Failure

Should a levee failure and associated flooding occur, there could be widespread temporary and permanent displacement of residents. Damages suffered from flooding could lead to the long-term disruption of industrial, agricultural and retail economic activities within the city of Sacramento. Dependent on the degree of damage caused, disruption of activities could lead to a reduction in employment and short- to long-term depressed economic conditions resulting from damage to industrial, retail and agricultural facilities and major transportation facilities that support their activities. These effects are explored in more detail below.

Levee failure and subsequent flooding of the city of West Sacramento would affect the entire city, causing substantial damage to structures, contents, and other property such as landscaping and automobiles. As described in Chapter 2, Alternatives, a population of 40,439 lives in 15,448 housing units within the city (Sacramento Area Council of Governments 2008b and 2008c). All of these residents could be displaced by a catastrophic flood event. Additionally, the city is home to 30,655 jobs (Sacramento Area Council of Governments 2008a), 734 commercial and industrial structures, 46 public structures and 27 park facilities, all of which would be affected by a flood event (HDR, Inc. 2009). Agricultural operations could also sustain major damage in a flood event; 22.6% of the land area within the city is either farmland or open space (City of West Sacramento 2009c). Depending on flood event depths, land damages are estimated to be up to $237,763,648 and structural damages could be up to $1,750 ,118,102 (PB 2007).

During the recovery period after a flood event, West Sacramento residents would require temporary housing, and displacement of many or all occupants would occur while levees, buildings, and other infrastructure were repaired. Businesses, social services, and other employers occupying affected structures would be forced to relocate. The potential number of displaced residents (over 40,000) and businesses (over 30,000 jobs) is so large that the demand for temporary quarters would likely exceed the available supply of vacant buildings surrounding the West Sacramento area. Thus, many displaced residents and businesses may be forced to relocate to areas a considerable distance from West Sacramento, resulting in substantial intermediate-term and long-term economic impacts to the West Sacramento area. These impacts include changes in employment numbers and patterns, changes in business and personal incomes, changes in tax revenues, and changes in regional economic activity.

A flood event in West Sacramento would also disrupt state and interstate highway, rail, and shipping traffic, causing long-term effects on the region's and the state's economy. West Sacramento has one of the most comprehensive transportation networks on the west coast. Its central geographic location and extensive north-south and east-west highway access has made it a major distribution center. High volumes of truck traffic pass through the city on I-80 and US 50/Business 80 every day, with truck traffic transporting approximately $63 billion worth of cargo annually through West Sacramento (HDR, Inc. 2009). Major transcontinental rail lines passing through the city provide commercial and passenger rail service to all parts of the nation, and the Port of West Sacramento runs domestic and international shipping services (City of West Sacramento 2009). Approximately 9.3 million tons of rail freight valued at approximately $5 billion travels through West Sacramento annually (HDR, Inc. 2009). Flooding of this transportation and distribution infrastructure would cut off major statewide and interstate commerce corridors and cause severe statewide economic effects.

These flood-related effects on population, housing, and socioeconomic conditions would be significant. Post-flooding conditions could result in short-term increases in employment for post-flooding cleanup and restoration activities, but these increases would likely not offset the potential losses.

3.12.4.1.2 Consequences of Flood Map Modernization

Additionally, as described in Chapter 2, Alternatives, without implementation of the program, there is a high likelihood that FEMA would remap the city out of flood hazard Zone X, which would prevent or constrain further development in the city. Prevention of further development would interrupt the preferred regional "blueprint" for future growth through 2035 adopted by the Sacramento Area Council of Governments (SACOG) and Valley Vision in 2004. SACOG envisions that West Sacramento would be the fastest growing city in the greater Sacramento region over coming decades because of its proximity to Sacramento's urban core and its many opportunities for reinvestment. SACOG's blueprint anticipates that more than 40,000 new dwelling units and over 50,000 new jobs will be established in West Sacramento by 2050. With a change in flood hazard designation, these 40,000 new dwelling units and the commercial and industrial developments associated with 50,000 new jobs would need to be redirected to other areas in the region over the next four decades (Sacramento Area Council of Governments 2004), and would likely significantly stunt the area's economic growth.

3.12.4.2 Flood and Recreation Program Alternatives

Effect SOC-1: Effects on Residents

In some cases, construction activities would be directly adjacent or in close proximity to residents, resulting in disturbance, inconvenience, and other adverse effects on their day-to-day activities or home-life. Construction activities could result in significant effects in areas such as transportation, visual resources, noise, utilities and public services, and construction-related hazards. Construction activities could result in temporary road closures, construction-related noise occurring (potentially 24/7), lights and glare from nighttime lighting sources, and utilities temporarily disconnected for durations that could last weeks or months. Effects related to specific resource areas such as transportation, noise, visual resources, public utilities, and public health and hazards are discussed in more detail in their respective sections (3.5, 3.7, 3.14, 3.16, and 3.17). An example of where these situations may occur is the residences built on the levee and high ground along the Sacramento

River North Levee as well as those near the landside levee toe. Along this portion of the levee, there is very little space to simultaneously allow construction activities and normal ingress/egress to residences on the levee and high ground. In addition, construction activities alongside the landside levee toe would be close to residences adjacent to the levee. A similar situation could arise anywhere there are residences or buildings built on top of or directly adjacent to levees such as the Yolo Bypass Levee, South Cross Levee, Sacramento River South Levee, and the DWSC East Levee. In some situations, residents would need to temporarily vacate their homes because there is the potential for them to no longer have transportation access, construction noise levels would be too high, or utilities may be disconnected for durations too lengthy for convenient day-to-day living. In these cases, WSAFCA may offer that residents temporarily vacate their properties to allow for construction activities to take place and residents may return upon completion of construction activities. In other cases (such as construction near homes that are adjacent to a levee), it may not be possible to provide relocation for all residents, or residents may not desire to relocate temporarily.

Where possible, to reduce these overall effects on residents, WSAFCA will provide compensation for living expenses for temporarily relocated residents, in compliance with Federal and state relocation laws, which are the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 (42 USC 4601 *et seq.*) and implementing regulation, 49 CFR Part 24; and California Government Code Section 7267 *et seq.* In addition, WSAFCA would develop a Resident Relocation Plan as described in Section 2.9 of Chapter 2, Alternatives, which would outline the process for providing notice for relocation, coordinating relocating activities, and providing security for homes that are vacated, among other issues related to temporary relocation. These overall effects on residents are considered potentially significant and unavoidable. In some cases, compensating residents as well as developing a Resident Relocation Plan would reduce these overall effects to a less-than-significant level; however, some effects would still be significant and unavoidable.

Program Alternatives Associated with This Effect

Implementation of all alternatives could cause Effect SOC-1.

Program	Alternative	
Flood	▪ Flood wall	▪ Seepage berm
	▪ Levee raise (in place)	▪ Sheet pile wall
	▪ Levee raise (adjacent)	▪ Slurry cutoff wall
	▪ Levee raise (full)	▪ Slope flattening
	▪ Closure structure	▪ Stability berm
	▪ Interior drain	▪ Rock slope protection
	▪ Jet grouting	▪ Setback levee
	▪ Relief wells	▪ Vegetation removal
Recreation	▪ Trails	▪ Developed water access
	▪ Riverside parks	▪ Special projects

Affected Reaches

Effect SOC-2 could occur in all nine program reaches: Sacramento River North, Sacramento River South, Port North, Port South, South Cross, DWSC East and West, Sacramento Bypass, and Yolo Bypass Levees.

Effect SOC-1 Finding	With Mitigation
Less than significant – Significant and unavoidable	N/A

Effect SOC-2: Loss of Agricultural Production and Employment

Several of the alternatives proposed under the program would require land acquisition to accommodate the expanded footprint of the levee system and/or parks system. WSAFCA would follow a selection process for levee alternatives that would take into account criteria such as the need to purchase real estate and land use compatibility, among others. However, if necessary, agricultural land adjacent to levees may be permanently acquired by WSAFCA and re-designated for flood control or other public use. As noted in Effect SOC-1, WSAFCA would comply with Federal and state laws regarding real property acquisition. Appropriate compensation for acquired land would reduce these effects on property owners to less than significant.

In addition, acquisition of agricultural land could cause currently farmed lands to be permanently taken out of production, resulting in the direct and indirect loss of employment within Yolo County.

The loss of employment would mainly be experienced by farmworkers and workers in the agricultural services sectors (e.g., farm equipment, seed, fertilizers, pesticides, gasoline).

For the purposes of this analysis, it is assumed that all currently farmed agricultural land (570 acres) within the program footprint could be permanently affected, and that all potentially affected agricultural land is producing the highest-yielding crop grown in West Sacramento (alfalfa). Under this scenario, the total annual crop yield lost as a result of the program would be roughly $738,000. This is less than one-fifth of one percent of Yolo County's total annual crop yield (which was $527,330,803 in 2008). However, WSAFCA would follow a selection process for levee alternatives that would take into account criteria such as the need to purchase real estate and land use compatibility, among others.

Changes in employment as a result of taking up to 570 acres of agricultural land out of production would not be significant in relation to the total employment in Yolo County and in the City of West Sacramento. This effect would be less than significant, and no mitigation is required.

Program Alternatives Associated with This Effect

Implementation of alternatives that expand the levee footprint and/or encroach into land that is in agricultural production could cause Effect SOC-2.

Program	Alternative	
Flood	▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Relief wells ▪ Seepage berm	▪ Slope flattening ▪ Stability berm ▪ Setback levee
Recreation	▪ Riverside parks	▪ Special projects

Affected Reaches

Effect SOC-2 could occur in four of the program reaches, depending on the flood program alternatives selected for those reaches. The reaches that could be affected are the Sacramento River South, South Cross, DWSC East, and Yolo Bypass Levee reaches. Although there is currently farmed land adjacent to the DWSC West Levee, it is assumed that the treatments selected in that reach would not affect any agricultural land.

Effect SOC-2 Finding	With Mitigation
Less than significant	N/A

Effect SOC-3: Temporary Disruption of Farming and Local Business Activity during Construction

Construction activities associated with implementation of the program have the potential to temporarily disrupt local farming activities and recreation-related businesses.

It is anticipated that several staging areas and temporary-access haul roads would be located on agricultural lands during construction. These lands would be temporarily taken out of production for the duration of the construction period. This is not anticipated to cause a substantial loss of employment, since the staging areas would affect a very small portion of currently farmed lands within the study area. These areas would be returned to pre-program conditions and agricultural production could resume once construction is completed. Additionally, as described in the environmental commitments outlined in Section 2.9 of Chapter 2, Alternatives, negotiations regarding any compensation for temporary loss of business/farm revenue would be accomplished in accordance with the Uniform Act and California Government Code Section 7267, *et seq*. The temporary effect on agriculture-related employment as a result of the location of staging areas is therefore considered less than significant. No mitigation is required.

As discussed in Section 3.15, Recreation, construction activities associated with implementation of the program have the potential to temporarily disrupt recreational activities in the study area. Although it cannot be quantified at this time, a disruption of recreational activities in the study area could lead to a corresponding indirect effect on recreation-related businesses in the area. These effects are anticipated to be minimal; however, WSAFCA would comply with Federal laws and state guidelines regarding compensation negotiations for temporary loss of business. This effect is considered less than significant.

Program Alternatives Associated with This Effect

Implementation of all alternatives could cause Effect SOC-3.

Program	Alternative	
Flood	▪ Flood wall	▪ Seepage berm
	▪ Levee raise (in place)	▪ Sheet pile wall
	▪ Levee raise (adjacent)	▪ Slurry cutoff wall
	▪ Levee raise (full)	▪ Slope flattening
	▪ Closure structure	▪ Stability berm
	▪ Interior drain	▪ Rock slope protection
	▪ Jet grouting	▪ Setback levee
	▪ Relief wells	▪ Vegetation removal
Recreation	▪ Trails	▪ Developed water access
	▪ Riverside parks	▪ Special projects

Affected Reaches

Effect SOC-2 could occur in all nine program reaches: Sacramento River North, Sacramento River South, Port North, Port South, South Cross, DWSC East and West, Sacramento Bypass, and Yolo Bypass Levees. However, effects associated with temporary conversion of agricultural land to staging areas would be limited to the program reaches with adjacent agricultural land, which are the Sacramento River South, South Cross, DWSC East and West, and Yolo Bypass Levee reaches.

Effect SOC-3 Finding	With Mitigation
Less than significant	N/A

Effect SOC-4: Temporary Increase in Employment in the Region during Construction

Construction activities associated with implementation of the program would temporarily increase employment and personal income in the study area, including in the city and Yolo and Solano Counties, as well as within the greater Sacramento region. Employment during the construction period would increase directly as a result of the labor needed for construction activities. Employment in the study area would also increase indirectly as personnel involved in construction of the program spend their wages and salaries in the study area.

Preliminary cost estimates anticipate that total construction-related expenditures associated with the program would be between $486,732,000 and $776,001,000 (HDR, Inc. 2009) spread over 10 to 15 years. This is an estimate of direct costs only, and does not include indirect/induced changes in employment and personal income resulting from program construction.

Program construction would therefore benefit the local economy by temporarily increasing employment and personal income. However, those changes would be very small relative to the total economic activity in the study area and in the Sacramento region in general. Construction-related employment would represent a small fraction of total employment and personal income levels. The effect on employment is considered beneficial.

Program Alternatives Associated with This Effect

Implementation of all alternatives would cause Effect SOC-4.

Program	Alternative	
Flood	▪ Flood wall	▪ Seepage berm
	▪ Levee raise (in place)	▪ Sheet pile wall
	▪ Levee raise (adjacent)	▪ Slurry cutoff wall
	▪ Levee raise (full)	▪ Slope flattening
	▪ Closure structure	▪ Stability berm
	▪ Interior drain	▪ Rock slope protection
	▪ Jet grouting	▪ Setback levee
	▪ Relief wells	▪ Vegetation removal
Recreation	▪ Trails	▪ Developed water access
	▪ Riverside parks	▪ Special projects

Affected Reaches

Effect SOC-4 would occur in all nine program reaches: Sacramento River North, Sacramento River South, Port North, Port South, South Cross, DWSC East and West, Sacramento Bypass, and Yolo Bypass Levee reaches.

Effect SOC-4 Finding	With Mitigation
Beneficial	N/A

Effect SOC-5: Continued Economic Development in the City of West Sacramento

Implementation of the program would reduce flood risks in the city, providing greater protection of life, property, and business pursuits. As described in Chapter 1, Introduction, the levees surrounding the city do not currently meet FEMA's minimum acceptable level of flood protection. Upgrading the flood protection of West Sacramento to a 200-year level would ensure that the city is not mapped into the floodplain on FEMA's Flood Insurance Rate Maps, thereby guaranteeing that no development restrictions or other impediments to growth are placed on the City by the Federal government. This will ensure that the City can move forward with the continued growth and economic development that is outlined in the City's 2008 *General Plan Issues and Opportunities Report*. This effect is considered beneficial.

Program Alternatives Associated with This Effect

Implementation of the entire program would cause Effect SOC-5. This could involve all proposed alternatives.

Program	Alternative	
Flood	▪ Flood wall ▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Closure structure ▪ Interior drain ▪ Jet grouting ▪ Relief wells	▪ Sheet pile wall ▪ Slurry cutoff wall ▪ Slope flattening ▪ Stability berm ▪ Rock slope protection ▪ Setback levee ▪ Vegetation removal ▪ Seepage berm
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

Effect SOC-5 would occur as a result of implementing the entire program. This would involve work in all nine program reaches: Sacramento River North, Sacramento River South, Port North, Port South, South Cross, DWSC East and West, Sacramento Bypass, and Yolo Bypass Levee reaches.

Effect SOC-5 Finding	With Mitigation
Beneficial	N/A

Section 3.13
Environmental Justice

3.13.1 Introduction

This section describes the regulatory and environmental setting for environmental justice, effects on low-income and minority populations that would result from the program and mitigation measures that would reduce significant effects.

The key sources of data used in the preparation of this section are listed below.

- *City of West Sacramento General Plan Policy Document* (City of West Sacramento 1990)
- U.S. Census Bureau QuickFacts (U.S. Census Bureau 2009a, 2009b, 2009c)

3.13.2 Affected Environment

3.13.2.1 Regulatory Setting

3.13.2.1.1 Federal

Executive Order 12898: Environmental Justice

Federal Executive Order 12898, Environmental Justice, requires that, to the greatest extent practicable and permitted by law, "each Federal agency shall make achieving environmental justice part of its mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations." Executive Order 12898 charges each cabinet department to "make achieving environmental justice part of its mission," with the EPA responsible for implementation of Executive Order 12898. The Council of Environmental Quality (CEQ) has oversight of the Federal government's compliance with Executive Order 12898 and NEPA.

3.13.2.1.2 State

Following the lead of Executive Order 12898, the State of California passed a series of environmental justice regulations in 2001. These laws define environmental justice as "the fair treatment of people of all races, cultures, and incomes with respect to the development, adoption, implementation, and enforcement of environmental laws, regulations, and policies."

3.13.2.2 Environmental Setting

3.13.2.2.1 Study Area

This section discusses the affected environment related to environmental justice in the study area. The study area is the city of West Sacramento, in Yolo County, and a small portion of east Solano County along the DWSC West Levee. Program effects occurring in Solano County would occur in a

rural area and would not have effects on a particular population; therefore, Solano County was not considered in this analysis. For comparison, the same demographic information presented for West Sacramento is also presented for Yolo County and the State of California.

3.13.2.2.2 Demographics

Local Setting

In 2000, Caucasians and Asians made up the largest two populations in the state, accounting for 59.5% and 10.9% of the population, respectively, while 16.8% of respondents claimed "other race." Those of Hispanic origin made up 32.4%, almost one-third of the State's population (U.S. Census Bureau 2008a).

The Federal government considers race and Hispanic origin to be two separate and distinct concepts. The Federal Office of Management and Budget's (OMB) standards for data on race generally reflect social definition recognized in this country, and do not conform to any biological, anthropological or genetic criteria. According to the revised OMB standards, race is considered a separate concept from Hispanic origin (ethnicity). For Census 2000, the questions on race and Hispanic origin were asked of every individual living in the United States. People who identify their origin as Spanish, Hispanic, or Latino may be of any race.

In 2000, Caucasians and Asians made up the largest two populations in Yolo County, accounting for 67.7and 9.9% respectively, while 13.8% of respondents claimed "other race." Those of Hispanic origin made up 25.9% of Yolo County (U.S. Census Bureau 2008b).

In 2000, Caucasians and Asians made up the largest two populations in the city of West Sacramento accounting for 65% and 7.2% of the population respectively, while 16% claimed "other race." Those of Hispanic origin made up 30% of the city (U.S. Census Bureau 2008c). Table 3.13-1 compares data regarding race in the study area in 2000 and 2005. Table 3.13-2 compares the household poverty status by city, county, and state.

Table 3.13-1. Race/Origin Characteristics by City/County/State, 2000 and 2005

	2000			2005/2006-2008		
	City of West Sacramento (percentage)	Yolo County (percentage)	State of California (percentage)	City of West Sacramento (percentage)	Yolo County (percentage)	State of California (percentage)
Race						
White	65.0	67.7	59.5	65.0	68.7	59.5
Black or African American	2.6	2	6.7	2.6	2.5	6.7
American Indian and Alaska Native	1.8	1.2	1.0	1.8	1.0	1.0
Asian	7.2	9.9	10.9	7.2	12.0	10.9
Native Hawaiian, other Pacific Islander	0.6	0.3	0.3	0.6	0.5	0.3
Some Other Race	16.0	13.8	16.8	16.0	11.3	16.8
Two or more races	6.9	5.2	4.7	6.9	4.2	4.7
Origin						
Hispanic	30.0	25.9	32.4	30.0	28.2	32.4

3.13.3 Environmental Consequences

This section describes the analysis of effects relating to environmental justice for the proposed program. It describes the methods used to determine the effects of the program and lists the thresholds used to conclude whether an effect would be significant. Measures to mitigate (i.e., avoid, minimize, rectify, reduce, eliminate, or compensate for) significant effects accompany each effect discussion.

3.13.3.1 Assessment Methods

The following methodology is based on the EPA's Environmental Justice Guidance (U.S. Environmental Protection Agency 1998), which states that "Minority populations should be identified where either (a) the minority population of the affected area exceeds 50 percent or (b) the population percentage of the affected area is meaningfully greater than the minority population percentage in the general population or other appropriate unit of analysis." As such, demographic data for the City of West Sacramento in the local setting and in Yolo County in the regional setting were compared to demographic data from the next highest unit of analysis, the State of California, to determine whether that specific area had a "meaningfully greater" percentage of minority or low-income population.

Demographic information was gathered for the city, county and state level. Proposed program environmental justice effects were analyzed by comparing census data from the local setting and regional setting with data for the State of California. Data were primarily collected from the U.S. Census Bureau 2000 Census and 2005 Census. The population data that are pertinent to the analysis of environmental justice include race, income, and age characteristics, and included:

- the percent of minority population (Black or African American, American Indian and Alaskan Native, Asian, Native Hawaiian and Other Pacific Islander, some other race, and two or more races);
- the percent of persons of Hispanic origin;
- the percent of population below the poverty level; and
- the percent of population residing below the U.S. Census Bureau poverty threshold, defined as a single person with an income below $8,840, or a family of four with an income below $16,588.

3.13.3.2 Determination of Effects

Effects pertaining to environmental justice were considered significant if the program would result in a disproportionate effect on minority or low-income communities.

3.13.3.3 Effects and Mitigation Measures

3.13.3.3.1 No Action Alternative

To recap from Chapter 2, Alternatives, the No Action Alternative is the continuation of the existing deficiencies along the nine levee reaches and absence of levee alternatives to increase the level of protection. Current levee operations and maintenance activities would continue. Without implementation of the program, there would be no potential displacement of homes or residences as a result of levee implementation.

Given levee conditions, under the No Action Alternative levee failure and subsequent flooding and inundation could temporarily or permanently displace residents over a wide area. Flood depth calculations prepared for the City of West Sacramento show that low-income and minority neighborhoods would not be disproportionately affected by flood inundation (PB 2007). Flooding could also result in temporary or long-term decreases in agricultural, industrial, and other economic enterprise in the city of West Sacramento that could result in a loss of jobs. However, this would likely affect populations of all income and ethnic classifications and would not result in a disproportionately high or significant effect on minority or low-income populations.

3.13.3.3.2 Flood and Recreation Program Alternatives

Effect EJ-1: Disproportionate Effect on Minority or Low-Income Populations

The proposed program would reduce the risk of flooding to existing residential, commercial, and industrial development in the WSAFCA service area. While there are low-income and minority populations present throughout the study area, the flood protection benefits of the program would reach all segments of the population in the city of West Sacramento.

In some cases, the implementation of levee alternatives (i.e., setback levees and adjacent levee raises) would extend the footprint of the levee landward, which may result in displacement of some residents. These types of treatments are proposed for the Sacramento River North and South Levees, Port North and Port South Levees, and the DWSC East Levee. These levee reaches encompass a large portion of the city of West Sacramento, contain a population of mixed demographics, and have residences that could be potentially affected by levee alternatives. Were displacement to occur, it would be directly adjacent to the levee and would result in the displacement of a few residences. No dividing of a community or disproportionate effect on low-income or minority communities would occur. In addition, levee treatments would be selected using criteria that consider the need to purchase real estate and land use compatibility, among others. Regardless of income and ethnic classifications, it is the program proponent's intention to avoid displacement of homes whenever possible and such treatments would be proposed only when it is absolutely necessary due to constraints such as engineering, construction, and the ability of the treatment to provide adequate flood protection for the entire population of the city. Furthermore, the program elements would not physically divide any city neighborhoods, and construction-related environmental effects (e.g. exposure to noise, dust, and traffic) would occur throughout the study area.

There is a known vagrant population that camps along the Sacramento River and DWSC East Levees within the city. The program could displace this population during construction activities. Recreational use of these areas as a result of the implementation of recreation program elements may deter camping activity. There is not enough data about this population to make conclusions

about the amount of people displaced. In addition, any loitering or camping along the river corridor is unlawful.

The program would not result in a significant disproportionate effect on minority or low-income populations.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall ▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Closure structure ▪ Interior drain ▪ Jet grouting ▪ Relief wells	▪ Seepage berm ▪ Sheet pile wall ▪ Slurry cutoff wall ▪ Slope flattening ▪ Stability berm ▪ Rock slope protection ▪ Setback levee ▪ Vegetation removal
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

Although different flood program alternatives are proposed for the reaches, this effect could occur in all nine program reaches.

Effect EJ-1 Finding	With Mitigation
Less than significant	N/A

Section 3.14
Visual Resources

3.14.1 Introduction

This section describes the regulatory and environmental setting for visual resources, effects on visual resources that would result from the program and mitigation measures that would reduce significant effects.

The key sources of data and information used in the preparation of this section are listed and briefly described below.

- *City of West Sacramento General Plan* (City of West Sacramento 2004)
- City of West Sacramento Municipal Code
- *Sacramento Riverfront Master Plan*, July 2003
- *Solano County General Plan*, December 2008
- Southport Design Guidelines, April, 1996, last amended November 2005
- *Southport Framework Plan*, May 1995, last amended 1998
- *Washington Specific Plan*, May 1996
- *West Sacramento Bicycle and Pedestrian Path Master Plan*, October 1991
- *West Sacramento Triangle Specific Plan*, Volume 1, June 1993
- *Yolo County General Plan*, July 1983, Open Space and Recreation Element last amended November 2002
- Zoning Regulations of the City of West Sacramento, March 2005

3.14.2 Affected Environment

3.14.2.1 Regulatory Setting

The proposed study area falls within the jurisdiction of the City of West Sacramento, Solano County, and Yolo County. Development in the city and counties is subject to the goals and policies of the *City of West Sacramento General Plan*, *Yolo County General Plan*, and specific area plans in the city, including visual resource and aesthetic policies, design guidelines, and ordinances such as tree preservation/removal ordinances.

3.14.2.1.1 Local

City of West Sacramento General Plan

The *City of West Sacramento General Plan* (City of West Sacramento 1990) identifies the following goals and policies for the implementation plan.

Urban Structure and Design

- **Goal B:** To enhance the relationship between the City and the Sacramento River.
  - **Policy B1:** The City shall seek to preserve the trees and other vegetation along the banks of the Sacramento River for their aesthetic qualities and environmental and ecological values.
  - **Policy B4:** The City shall promote the development of important visual and scenic areas along the riverfront, including around the barge canal, for public access, including water-related activities.
- **Goal D:** To maintain and enhance the quality of the City's landscape and streetscape.
  - **Policy D1:** The City shall endeavor to protect the tree canopy created by mature trees in existing developed areas and in newly developing areas.
  - **Policy D2:** The City shall require that all new development incorporate the planting of trees and other vegetation to extend the vegetation pattern of older adjacent neighborhoods into new development.

City of West Sacramento Tree Preservation Ordinance

The City of West Sacramento Tree Preservation Ordinance is found in Chapter 8 Health and Safety of the City's municipal code. The ordinance regulates the removal and preservation of heritage trees and landmark trees.

A heritage tree is any living tree with a trunk circumference of 75 inches or more or a native oak with a trunk circumference of 50 inches or more, both measured 4 feet 6 inches from ground level. The circumference of multi-trunk trees is based on the sum of the circumference of each trunk.

A landmark tree is any tree or stand of trees that is especially prominent, stately, or that is of historic significance as designated by the city council.

It is unlawful to perform any of the following acts affecting a landmark or heritage tree without a tree permit issued by the tree administrator:

- move, remove, cut down, poison, set fire to or permit fire to burn close to, or perform or fail to perform any act that results in the unnatural death or destruction of a landmark or heritage tree;
- perform any activity that will interfere with or retard the natural growth of any landmark or heritage tree;
- perform any work or permit any work to be performed within the dripline area of a landmark or heritage tree that would endanger the tree;
- trim or prune any branch of a landmark or heritage tree that is 5 inches in diameter or greater;

- change the appropriate amount of irrigation or drainage water provided to any landmark, heritage, or street tree;
- trench, grade, pave, or otherwise damage or disturb any exposed roots within 1 foot outside the dripline area of any landmark, heritage, or street tree;
- park or operate any motor vehicle within 1 foot outside the dripline area of any landmark, heritage, or street tree;
- place or store any equipment or construction materials within 1 foot outside the dripline area of any landmark, heritage, or street tree;
- place, apply, or attach any signs, ropes, cables, or any other items to any landmark, heritage, or street tree;
- cut or trim any branch of any landmark, heritage, or street tree that is 5 inches in diameter or greater; or
- place or allow to flow any oil, fuel, concrete mix, or other deleterious substance into or over areas within 1 foot outside the drip area of any landmark, heritage, or street tree.

A tree permit requires the applicant to replace the tree with a living tree(s) on the property or within the city in a location approved by the tree administrator. The replacement tree(s) must be replaced if it dies any time with 3 years of the initial planting. Replacement is not required for trees posing a risk or hosting a parasitic plant.

Replacement trees are required at the ratio of 1-inch diameter of replacement plant for every 1-inch diameter of tree removed. Replacement trees may be a combination of 15-gallon-size trees, which are the equivalent of a 1-inch-diameter tree, or 24-inch box trees, which are the equivalent of a 3-inch-diameter tree.

If trees cannot be replaced on site, the applicant must pay an in-lieu fee, which will be used to purchase and plant trees elsewhere in the city of West Sacramento.

City of West Sacramento Zoning Ordinances

The following zoning ordinances are citywide design standards that would apply to the proposed program. The ordinances listed below have been identified for their direct relation to program aesthetics; however, other portions of these ordinances indirectly relate to aesthetics, as they are drivers of design, and it is recommended that these ordinances be referred to in their entirety for details.

Title 17.31 Fences, Walls and Hedges

17.31.010 Maximum Heights

17.31.011 Three Foot Limit

No fencing, walls, structures or hedges over 3 feet in height (except in the R-1-A and R-2 zone) shall be allowed in the following areas:

A. In Residential zones in front setbacks;

B. In Residential zones in street side setbacks within forty-five (45) feet of a street corner;

C. In any zone within ten (10) feet of any street property line or within five feet of the sidewalk where separated sidewalks exist.

D. In any zone within a triangle formed by measuring thirty (30) feet from any street corner down the lot lines and connecting across the property;

E. In Residential zones within a triangle formed by measuring fifteen (15) feet from the rear street side corner of a corner lot down the lot lines and connecting across the property.

17.31.012 Four Foot Limit

In the R-1-A and R-2 north of the Deep Water Ship Channel, zone the maximum height allowed in A., B., and C., above shall be four (4) feet for fences which are at least 95% open to views through the fence.

17.31.013 Seven Foot Limit

No fence or wall over seven (7) feet in height shall be allowed within any setback area in a residential zone.

17.31.020 Required Screening

A. A solid hedge, vine-covered chain-link fence or masonry wall of a minimum of six (6) feet in height shall be provided around the perimeter of all exterior storage or work areas and loading areas (see Landscape Development Guidelines). Display areas for the sale or rental of heavy equipment or commercial vehicles are exempt from the screening requirement.

B. A masonry or concrete wall of a minimum of five (5) feet in height shall be provided around outdoor refuse collection areas (see Section 17.35 and Landscape Development Guidelines).

C. Solid fences or sound walls shall be provided between land uses as required by the Landscape Development Guidelines, The Screen Canopy.

Title 17.32.000 Performance Standards

17.32.010 Purpose and Intent: It is the purpose and intent of these standards to prevent any use which may create dangerous, injurious, noxious or otherwise objectionable conditions.

17.32.020 Applicability: These Performance Standards shall apply to all uses and properties in the City as of the date of adoption of this Ordinance, including existing uses. The Planning Commission may approve extensions for compliance for existing uses with a contract and schedule for full compliance. The maximum time limit of an extension shall be five years and shall be based on the degree of expenditure needed to achieve full compliance compared to the total value of the improvements related to the use and the degree of hazard or impact to the adjoining properties and the community from the existing non-compliance with the Standards.

17.32.030 Standards

N. Lighting: Utilize the Illuminating Engineers Society of North America (IESNA) standards when reviewing exterior lighting for commercial and industrial zones of the City.

Title 17.33.000 Signs

17.33.010 Purpose and Intent: The purpose of this chapter is to create a comprehensive and balanced system of signs which will allow adequate business identification and communication with a quality appearance. Signs authorized under this chapter should:

A. Encourage a desirable urban character consistent with the General Plan;

B. Preserve and improve the appearance of the city as a place to live, work and visit;

C. Eliminate confusing, distracting, or dangerous sign displays which interfere with vehicular traffic;

D. Promote commerce;

E. Provide for fair and equal treatment of sign users;

F. Promote ease of sign ordinance administration; and

G. Provide for eventual elimination of pre-existing, non-conforming signs on a fair and equitable basis.

Sacramento Riverfront Master Plan

The SRMP is a collaborative planning document developed by the Cities of Sacramento and West Sacramento along with Yolo and Sacramento Counties, and used to guide riverfront development along the Sacramento River. The SRMP places emphasis on improved public open space along the riverfront and enhancement and preservation of riverine, riparian, and upland forest environments to provide a richer experience for the user (Wallace Roberts and Todd 2003).

Solano County General Plan

The *Solano County General Plan* (Solano County 2008) identifies the following goals and policies for the implementation plan.

Resources

Goal RS.G-4: Preserve, conserve, and enhance valuable open space lands that provide wildlife habitat; conserve natural and visual resources; convey cultural identity; and improve public safety.

Biological Resources

Policy RS.P-6: Protect oak woodlands and heritage trees and encourage the planting of native tree species in new developments and along road rights-of-way.

Sacramento–San Joaquin Delta Policies

Policy RS.P-21: Preserve and protect the natural resources of the Delta including soils and riparian habitat. Lands managed primarily for wildlife habitat should be managed to provide inter-related habitats.

Scenic Resources

Policy RS.P-35: Protect the unique scenic features of Solano County, particularly hills, ridgelines, wetlands, and water bodies.

Southport Implementation Plan

The Southport Implementation Plan is a component of the overall *Southport Framework Plan* that provides an overview of the approval process, development and infrastructure phasing, natural resource issues, and affordable housing requirements. Directly related to aesthetics and the character of Southport, the implementation plan outlines habitat conservation measures to protect sensitive resources such as riparian woodland along the Sacramento River, retains agriculture areas with buffer zones, and complies with the City's tree preservation ordinance by protecting native trees (City of West Sacramento 1995).

West Sacramento Bicycle and Pedestrian Path Master Plan

The *West Sacramento Bicycle and Pedestrian Path Master Plan* (Callander Associates 1991) identifies the following objectives and policies.

Objective 4—Acquisition, Implementation and Maintenance: Provide detailed planning and implementation of the path system as directed by the Department of Public Works and Department of Parks and Community Services.

Policy 4.5: Preserve natural vegetation, wherever possible, and provide low maintenance, drought-tolerant planting along paths as needed for climate amelioration, buffering and aesthetic enhancement.

Policy 4.6: Acknowledge visibility requirements of users in design of planting and preservation of natural vegetation.

West Sacramento Triangle Specific Plan

The *West Sacramento Triangle Specific Plan* (Zimmer Gunsul Frasca 1993) is a comprehensive planning document used to guide development within the "Triangle" area of West Sacramento. The Triangle is bounded by SR 275, Business 80, and the Sacramento River and includes a small parcel south of Business 80. The Triangle is subdivided into five neighborhoods: the Waterfront, the Core, the Park Blocks, the Parkway Edge, and the RGA Edge. Each planning area has guidelines for preserving key views (e.g., views to the Sacramento River and Tower Bridge). The study area is located within the Waterfront planning area, and the *Triangle Specific Plan* identifies the following policies and guidelines for the Waterfront.

Guideline—Required View Corridors: Views to the east from River Road may not be blocked for more than 220 feet measured parallel to the waterfront. Eastward extensions of east-west street right of ways are to be maintained as view corridors.

Guideline—Park Blocks View Corridor Easement: Provide and maintain a 50 foot wide open space easement on axis with the Parks Blocks between River Road and the Sacramento River. The purpose of this easement is to provide pedestrian access to the river bank and views of the Tower Bridge from the Park Blocks.

Guideline—Riverfront Parks: Provide views to the Sacramento River and the Downtown Sacramento skyline from the Promenade. The use of lower growing plant material and high canopy upper story trees will create an inviting and diverse visual experience.

Guideline—Respect views to waterfront: Establish landscape view corridors to provide physical access to the waterfront and Sacramento River. Design and orient landscape areas to maximize views and access towards the river.

Yolo County General Plan

The *Yolo County General Plan* (Yolo County 1983) identifies the following goals, objectives and policies for the implementation plan.

Scenic Highways Policies

Policy SH-5: Protection. Yolo County shall regulate and guide land uses, recreation, circulation, conservation, and open spaces and shall require retention or conservation of natural features and vegetation along both State and locally designated scenic highways.

Policy SH-6: River Roads. Yolo County shall consider designating "river roads" as designated scenic highways.

Policy SH-7: Natural Vegetation and Landscaping. Yolo County shall require retention, of existing trees and vegetation and natural landforms, and shall require landscaping to enhance scenic qualities and/or screen unsightly views, and shall implement regulations to prohibit removal of trees along public rights-of-way without consideration of their scenic or historic value, and shall implement tree conservation or enhancement in new development, with emphasis on oak preservation.

Recreation Policies

Policy REC-1: Recreation Basic. Yolo County acquires, maintains and provides a variety of park, open and natural areas for recreational and leisure pursuits at the regional, community and neighborhood level through means of California statute, established land use controls, regulations, real property transfer, and the advice, guidance and cooperation of other jurisdictions and through coordination with other elements of this general plan, as amended. It shall be the basic recreation policy of the County to: Protect and preserve as many of the County's recreational and scenic resources as possible.

Yolo County Open Space and Recreation Element

The Yolo County Open Space and Recreation Element (Yolo County 2002) of the general plan identifies the following goals, objectives, and policies for the implementation plan.

Goal OG-7: Preserve aesthetic resources and values.

Objective OO-8: Protection of identified areas of unique historical or cultural value within the county and preservation of those sites for educational, scientific and aesthetic purposes.

Objective OO-9: Identification and preservation of scenic corridors and viewsheds.

Policy OP-7: Development shall be directed away from naturally occurring riparian areas and wetlands.

Yolo County Oak Woodland Conservation and Enhancement Plan

Many residents and visitors enjoy the oak woodlands in Yolo County for their scenic beauty while recreating and driving through the county. The *Yolo County Oak Woodland Conservation and Enhancement Plan* promotes voluntary efforts to conserve and enhance the county's oak woodlands, which provide significant aesthetic, ecological, and economic benefits (Yolo County 2007).

3.14.2.2 Environmental Setting

This section discusses the existing conditions related to visual resources in the study area. The methods used to evaluate visual resources and viewer groups in general are described, and the visual resources in the region and study area are characterized.

3.14.2.2.1 Study Area

For the purposes of this program document, the study area consists of the program footprint plus an approximately 500-foot-wide landside buffer. The study area occurs along the following levee reaches: Sacramento River North, Sacramento River South, Port North, Port South, South Cross, DWSC West, DWSC East, Yolo Bypass, and Sacramento Bypass Levee reaches.

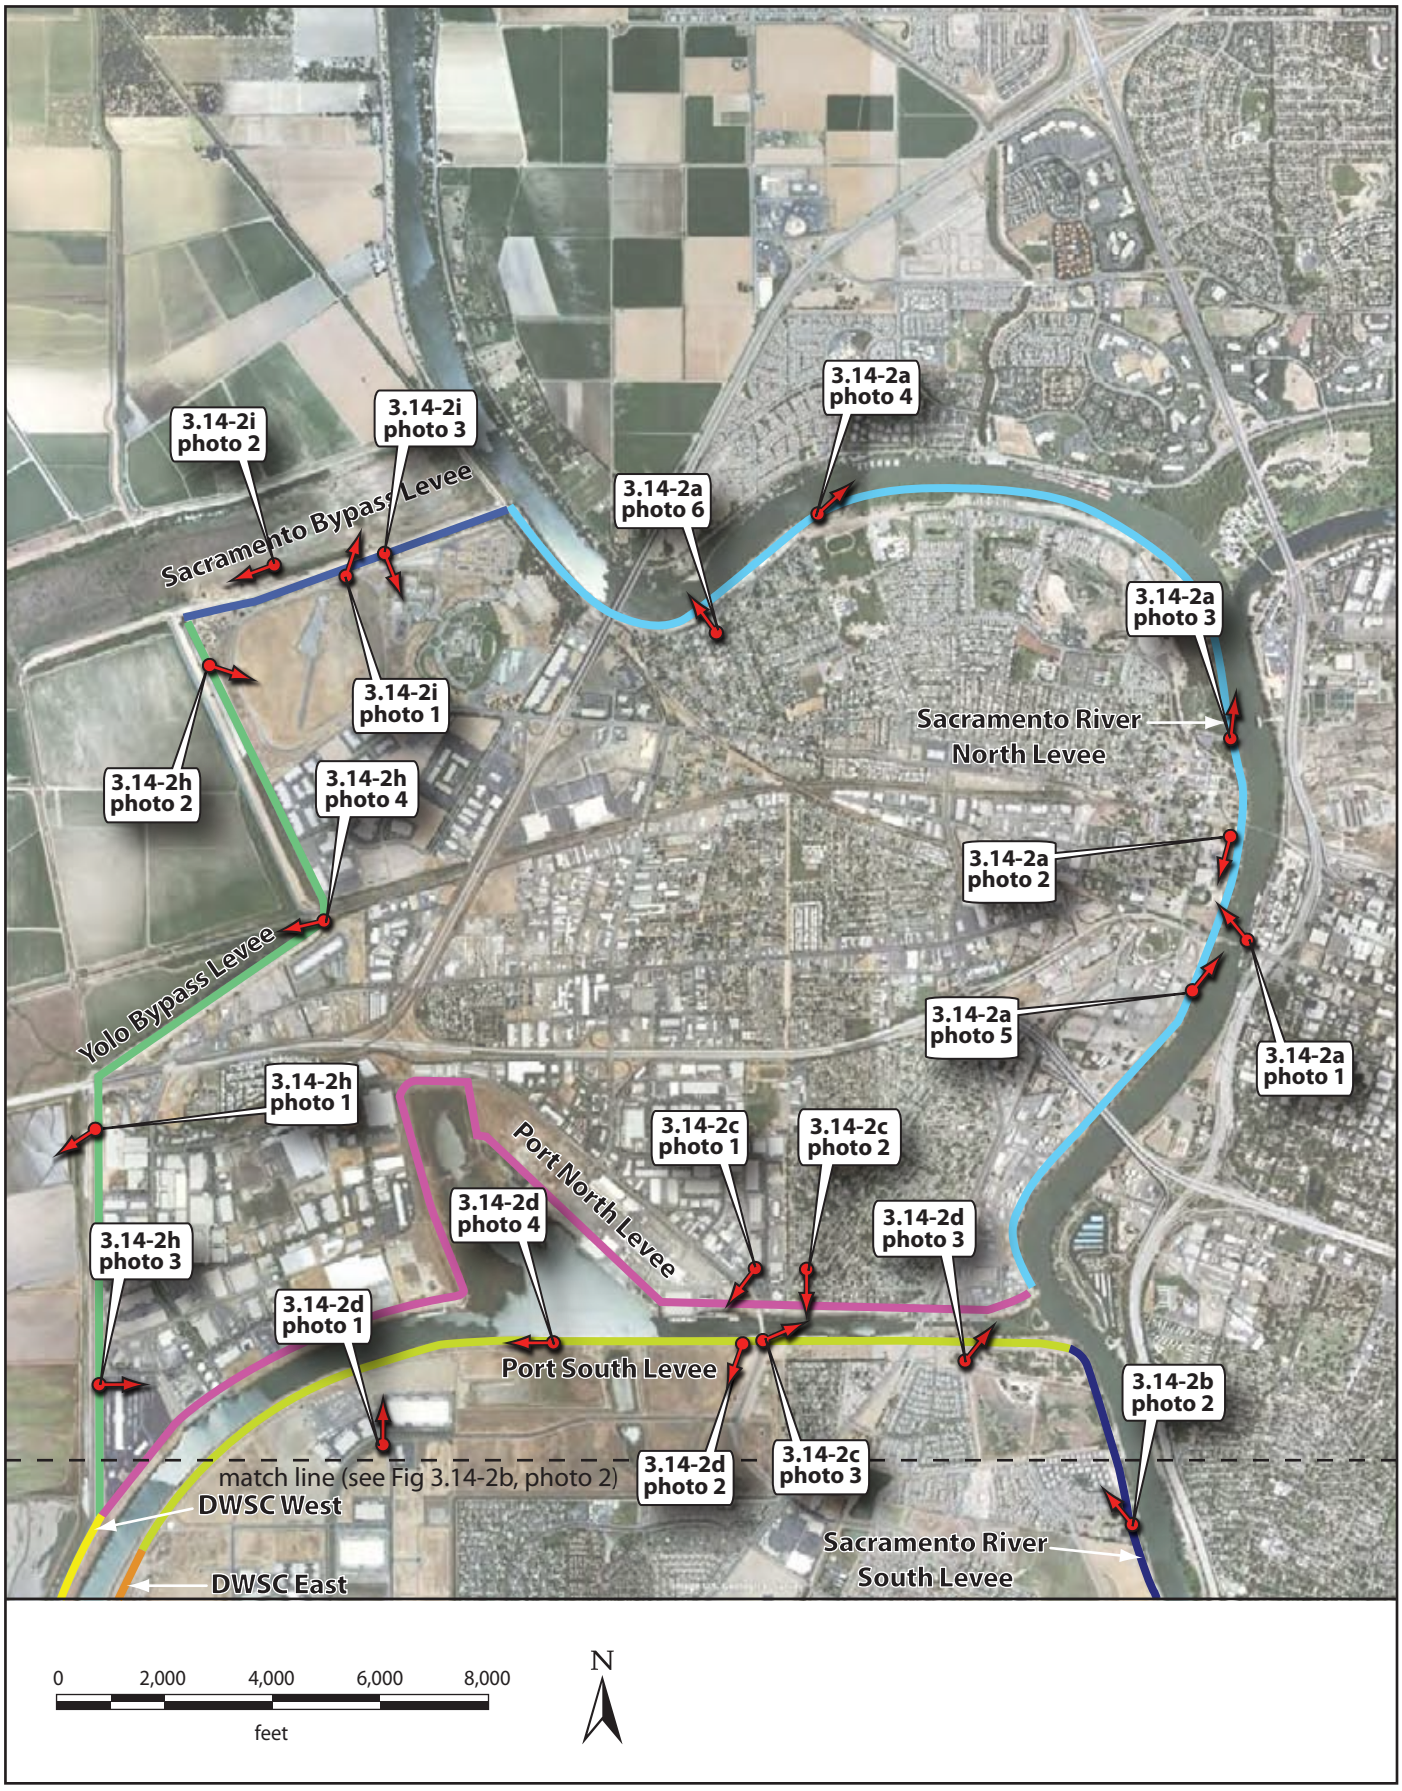
Representative photographs of the study area were taken on November 29, 2007 and February 5, 2009, to document key views and typical conditions. The photograph locations are shown on Figure 3.14-1, and the photographs are contained in Figure 3.14-2a–i.

3.14.2.2.2 Concepts and Terminology

Identifying a study area's visual resources and conditions involves three steps:

- Objective identification of the visual features (visual resources) of the landscape.
- Assessment of the character and quality of those resources relative to overall regional visual character.
- Determination of the importance to people, or *sensitivity*, of views of visual resources in the landscape.

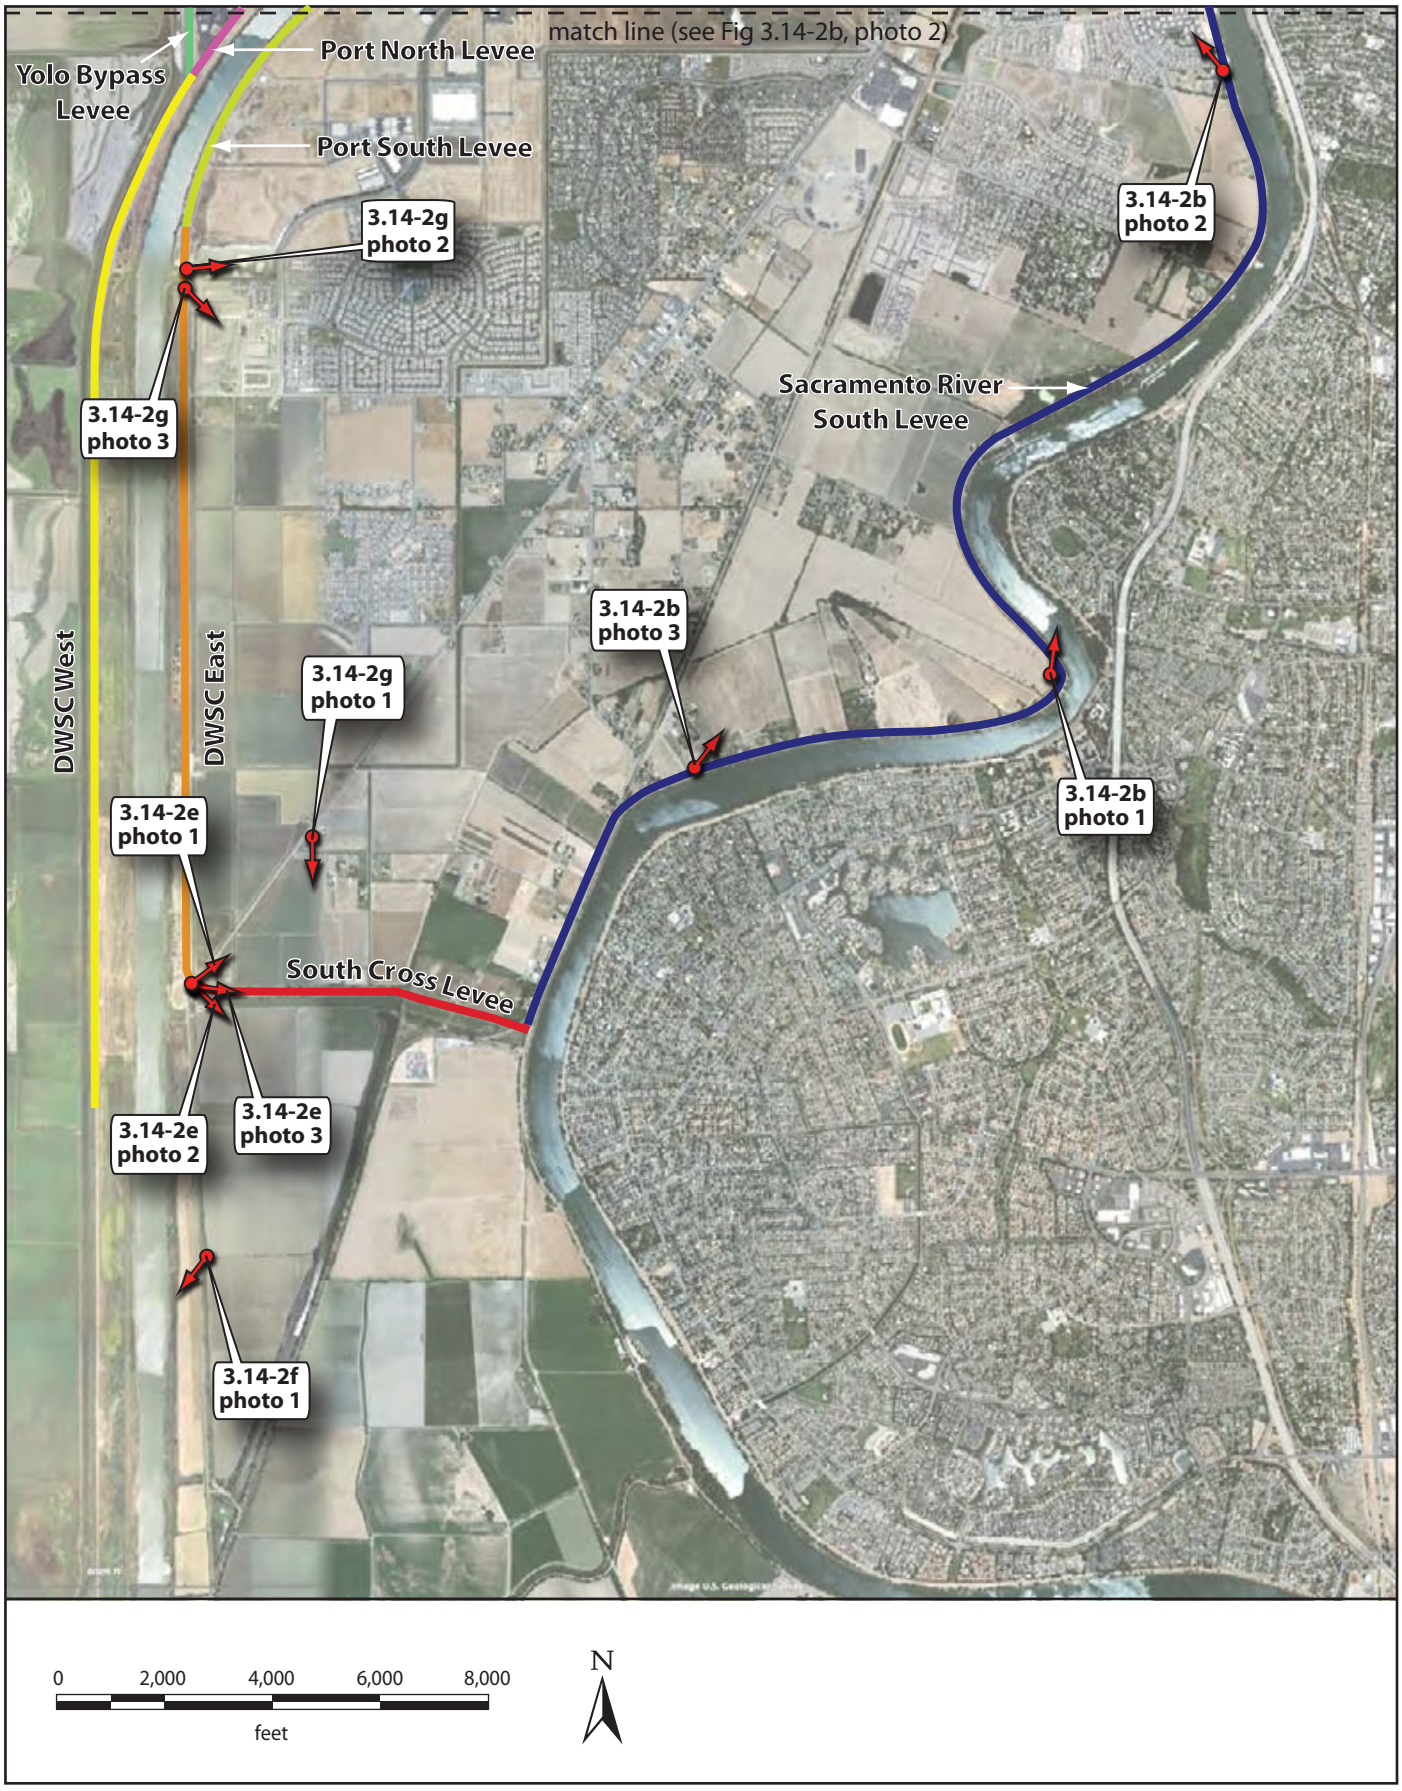
Because evaluating visual effects is inherently subjective, Federal and professional standards of visual assessment methodology have been used to determine potential effects on aesthetic values of the study area (see Environmental Consequences below). The aesthetic value of an area is a measure of its visual character and quality, combined with the viewer response to the area (Federal Highway Administration 1988). Scenic quality can best be described as the overall impression that an individual viewer retains after driving through, walking through, or flying over an area (U.S. Bureau of Land Management 1980). Viewer response is a combination of viewer exposure and viewer sensitivity. Viewer exposure is a function of the number of viewers, number of views seen, distance of the viewers, and viewing duration. Viewer sensitivity relates to the extent of the public's concern for a particular viewshed. These terms and criteria are described in detail below.



Visual Character

Natural and artificial landscape features contribute to the visual character of an area or view. Visual character is influenced by geologic, hydrologic, botanical, wildlife, recreational, and urban features. Urban features include those associated with landscape settlements and development, including roads, utilities, structures, earthworks, and the results of other human activities. The perception of visual character can vary significantly seasonally, even hourly, as weather, light, shadow, and elements that compose the viewshed change. The basic components used to describe visual character for most visual assessments are the elements of form, line, color, and texture of the landscape features (USDA Forest Service 1974; Federal Highway Administration 1988). The appearance of the landscape is described in terms of the dominance of each of these components.

Visual Quality



Visual quality is evaluated using the well-established approach to visual analysis adopted by Federal Highway Administration, employing the concepts of vividness, intactness, and unity (Federal Highway Administration 1988; Jones et al. 1975), which are described below.

- *Vividness* is the visual power or memorability of landscape components as they combine in striking and distinctive visual patterns.
- *Intactness* is the visual integrity of the natural and human-built landscape and its freedom from encroaching elements; this factor can be present in well-kept urban and rural landscapes, and in natural settings.

00875.07 EIS\EIR (8-09)

Figure 3.14-1
Key Viewpoints

00875.07 EIS\EIR (8-09)

Figure 3.14-1
Key Viewpoints

- *Unity* is the visual coherence and compositional harmony of the landscape considered as a whole; it frequently attests to the careful design of individual components in the landscape.

Visual quality is evaluated based on the relative degree of vividness, intactness, and unity, as modified by the visual sensitivity of the viewers. High-quality views are highly vivid, relatively intact, and exhibit a high degree of visual unity. Low-quality views lack vividness, are not visually intact, and possess a low degree of visual unity.

Viewer Exposure and Sensitivity

The measure of the quality of a view must be tempered by the overall sensitivity of the viewer. Viewer sensitivity or concern is based on the visibility of resources in the landscape, proximity of viewers to the visual resource, elevation of viewers relative to the visual resource, frequency and duration of views, number of viewers, and type and expectations of individuals and viewer groups.

The importance of a view is related in part to the position of the viewer relative to the resource; therefore, visibility and visual dominance of landscape elements depend on their placement within the viewshed. A viewshed is defined as all of the surface area visible from a particular location (e.g., an overlook) or sequence of locations (e.g., a roadway or trail) (Federal Highway Administration 1983). To identify the importance of views of a resource, a viewshed must be broken into distance zones of foreground, middleground, and background. Generally, the closer a resource is to the viewer, the more dominant it is and the greater its importance to the viewer. Although distance zones in a viewshed may vary between different geographic regions or types of terrain, the standard foreground zone is 0.25 to 0.5 mile from the viewer, the middleground zone is from the foreground zone to 3 to 5 miles from the viewer, and the background zone is from the middleground to infinity (USDA Forest Service 1974).

Visual sensitivity depends on the number and type of viewers and the frequency and duration of views. Visual sensitivity is also modified by viewer activity, awareness, and visual expectations in relation to the number of viewers and viewing duration. For example, visual sensitivity is generally higher for views seen by people who are driving for pleasure, people engaging in recreational activities such as hiking, biking or camping, and homeowners. Sensitivity tends to be lower for views seen by people driving to and from work or as part of their work (USDA Forest Service 1974; Federal Highway Administration 1983; U.S. Soil Conservation Service 1978). Commuters and non-recreational travelers typically have fleeting views and tend to focus on commute traffic, not on surrounding scenery; therefore, they are generally considered to have low visual sensitivity. Residential viewers typically have extended viewing periods and are concerned about changes in the views from their homes; therefore, they are generally considered to have high visual sensitivity. Viewers using recreation trails and areas, scenic highways, and scenic overlooks are usually assessed as having high visual sensitivity.

Judgments of visual quality and viewer response must be made based in a regional frame of reference (U.S. Soil Conservation Service 1978). The same landform or visual resource appearing in different geographic areas could have a different degree of visual quality and sensitivity in each setting. For example, a small hill may be a significant visual element on a flat landscape but have very little significance in mountainous terrain.

3.14.2.2.3 Viewer Groups and Viewer Responses

The primary viewer groups in the study area are persons living or conducting business near levees; travelers using the interstates, highways, and smaller local roads (including those on levee crowns); and recreationists (boaters, beachgoers, and anglers using canals, creeks, and rivers; trail users; equestrians; bicyclists; joggers; etc.). All viewer groups have direct views of the study areas described above.

Residents

Suburban and rural residents are located directly adjacent to levees or are separated from them by local streets or a similar corridor. Suburban residences mostly are oriented inward toward the developments, and only residences on the outer edge of the developments have middleground and background views of levees. The separation and orientation of rural residences allow inhabitants to have direct views over agricultural fields toward levees. Both suburban and rural residents are likely to have a high sense of ownership over their adjacent waterways, the open space that surrounds them, the recreational opportunities they provide, and their inherent scenic quality. Because of their potential exposure to such views, short distance from the study areas, and sense of ownership, these residents are considered to have high sensitivity to changes in the viewshed.

Businesses

Viewers from industrial, commercial, government, and educational facilities have semi-permanent views from their respective facilities. Situated in different locations throughout the study areas, these facilities' views range from views limited by the levees to sweeping views that extend out to the background. Employees and users of these facilities are likely to be occupied with their work activities and tasks at hand. However, some of these facilities depend on the waterways in the study area as a destination spot and source of income (e.g., Port of West Sacramento).

People using these facilities often travel to and from work and spend leisure time on the waterways and levees. For these reasons, their limited viewing times, their focus on tasks at hand, and the current use of the levees, this viewer group is considered to have moderate sensitivity to changes in views.

Roadway Users

Roadway users' vantages differ based on the roadway they are traveling and elevation of that roadway. The majority of views are mostly limited to the foreground by suburban, commercial, and industrial development; vegetation; and the levees themselves. Views to the middleground and background are present but are limited to areas where structures that otherwise would conceal background views from the roadway are set back. However, if the vantage is elevated, as on portions of Capital City Freeway, bridges crossing over the Sacramento River, levee roads (e.g., South River Road), and other local roadways, most views of the surrounding mountain ranges (Vaca Mountains, Coast Range, and Sierra Nevada), waterways (American and Sacramento Rivers, DWSC, Yolo Bypass when flooded) and open space areas (agriculture, parkways) are only partially obstructed by the rooflines and mature vegetation in the area.

Travelers use roadways at varying speeds; normal highway and roadway speeds differ based on the traveler's familiarity with the route and roadway conditions (e.g., presence/absence of rain). Single views typically are of short duration, except on straighter stretches where views last slightly longer.

Viewers who frequently travel these routes generally possess moderate visual sensitivity to their surroundings. The passing landscape becomes familiar to these viewers, and their attention typically is not focused on the passing views but on the roadway, roadway signs, and surrounding traffic. Viewers who travel local routes for their scenic quality generally possess a higher visual sensitivity to their surroundings because they are likely to respond to the natural environment with a high regard and as a holistic visual experience. Furthermore, there are scenic stretches of roadway passing through the study areas that offer sweeping views of the surrounding area that are of interest to motorists, especially when traveling on the bridges or levee tops. For these reasons, viewer sensitivity is moderate among most roadway travelers.

Recreationists

Recreational users view the study areas from parks, waterways, roadways, trails, and from the levees themselves. Recreational uses consist of boating and fishing, hunting in the bypasses, birding, walking, running, jogging, and bicycling along trails, levee crowns, and local roads. Users of the waterways are likely to seek out natural areas within the corridor, such as sand and gravel bars and beaches, in addition to using the waterways as a resource. Waterway users have differing views based on their location in the landscape and are accustomed to variations in the level of industrial, commercial, suburban, and recreational activities occurring within the study area. The amount of vegetation present along the levees creates a softened, natural edge that is enjoyed by all recreationists. Local recreationists also have a high sense of ownership over the waterways and corridors they use for recreation, and these areas are highly valued throughout the greater Sacramento area.

Viewer sensitivity is high among recreationists using the study areas because they are more likely to value the natural environment highly, appreciate the visual experience, have a high sense of ownership, and be more sensitive to changes in views.

3.14.2.2.4 Visual Character of Region

The study area is located in the city of West Sacramento, in the southern portion of the Sacramento Valley, directly west of the city of Sacramento. The region, as discussed in this section, is considered the area within 30 miles of the study area. The region consists primarily of agricultural and suburban land uses, with the urban core of Sacramento anchoring the northeastern boundary. Although many of the western portions of the region are still in agricultural production, there has been and continues to be an increasing conversion of agricultural land to urban and suburban land uses. This trend is evident around the outskirts of Sacramento. Many of the small, agrarian communities in this region, such as Rio Linda, Dixon, and Woodland, are experiencing similar growth and land use conversions.

Agricultural land, planted predominantly with row crops, stretches for miles in the region. A patchwork of fields separates the urban center of Sacramento, and its suburban outskirts, from smaller, outlying cities. These fields offer expansive views that, when haze is at a minimum, extend over agricultural fields and recent development in the foreground to the middleground and background. The high-rise buildings of downtown Sacramento can be seen in the middleground, rising up above the eastern tree line. Background views to the Sierra Nevada foothills are more rarely seen to the east while views of Mount Vaca and the Sutter Buttes are more commonly seen to the west and north. These types of landscape views are strongly characteristic of the Sacramento Valley and have contributed to the region's identity.

Growth radiating out from city and town cores is reducing the amount of agricultural land in the region and closing the gap between the Sacramento metropolitan region and smaller, outlying cities. This growth is changing the visual character from rural to suburban. Development of the smaller cities in the region, including West Sacramento, is typified by a growing core of residential, commercial, and some industrial land uses with agricultural fields surrounding the city outskirts. Residential and commercial development in the region tends to be homogenous in nature, having similar architectural styles, building materials, plan layouts, and commercial entities; and development often lacks a distinctive character from one city to the next.

West Sacramento is bounded by the Sacramento River Bypass to the north, Sacramento River to the north and east, and the DWSC and Yolo Bypass to the west. It is developing in a pattern similar to other cities except the northern portions are already developed, and the natural and human-made waterways and bypasses prevent further development to the north, east, and west. Therefore, most major development is spreading southward where vast acreage of agricultural land remains. Development in the northern, eastern, and western portions of West Sacramento is occurring on disjunct parcels of agricultural land or redevelopment and infilling of vacant parcels in older portions of the city.

Overall, a mix of developed and natural landscapes characterizes the region. The landscape pattern is influenced by development sprawling from existing city cores and the major roadways in the region. Water features in the region include the Sacramento and American Rivers and their tributaries, the DWSC, Yolo Bypass (when flooded), numerous north Delta sloughs, and smaller local irrigation ditches.

3.14.2.2.5 Visual Character of Study Area

The visual character of each of the nine reaches in the study area is described below.

Sacramento River North Levee

The Sacramento River North Levee generally runs north-south between the Sacramento Bypass to the north and the Port North Levee to the south and serves as the eastern boundary to the city. The area includes the urban core of the city, commercial and industrial developments, residential communities, open space, developed riverfront parkways, and riparian corridors.

Commercial developments are located adjacent to the Sacramento River between the I Street and West Capitol bridges. Manicured landscapes and mature trees surround the commercial buildings. A developed riverfront parkway is also situated in this reach of levee. The commercial developments and riverfront parkway are also visible to recreationists on the river (Figure 3.14-2a, Photo 1). Industrial developments are located south of West Capitol Avenue and continue to the Port North Levee. The industrial facilities block the views to the east of the Sacramento River, downtown, and beyond from travelers on Jefferson Boulevard and residences west of Jefferson Boulevard.

Residences with primary views of the study area are located on the northern portion of this levee reach and tend to be older suburbs. In some cases residences directly abut or are separated from levees only by local roadways (Figure 3.14-2a, Photo 2). These homes are commonly surrounded by fencing and mature landscaping, including tall native and non-native trees, even when located directly adjacent to a levee. Throughout this area, there are access locations where people can reach the river and use the levee crown for recreation. A new gated development was built within the last few years adjacent to the river with some homes constructed directly atop the levee. These homes

Photo 1. Looking northwest across the Sacramento River. This photo depicts the commercial development along the riverbank and riverfront park. Remnant riparian vegetation can be seen in the middleground.

Photo 2. Looking northeast along Riverbank Road. This photo depicts a local road separating the adjacent residences from the levee embankment.

Photo 5. Looking north across the Sacramento River toward the Tower Bridge and Old Sacramento. This photo depicts the mature riparian trees and associated vegetation that exists on the waterside levee slope and toe.

Photo 6. Looking north at the Sacramento River North Levee. This photo depicts the limited views from the residences along the majority of this levee reach. DWR's maintenance yard can be seen on top of the levee.

00875.07 EIS (7-09)

Figure 3.14-2a
Representative Photos of Program Area and Key Views

are large two-story buildings with small lots and have not been designed to meld with the older communities (with respect to layout, architectural style, and streetscaping).

The Broderick Boat Ramp Park is situated north of the I Street Bridge and provides an open space area vegetated with mature riparian trees that can be viewed by adjacent roadway users and residents, as well as, recreationists on the river (Figure 3.14-2a, Photo 3). Farther north another open space area atop the levee is also vegetated with mature riparian trees and can be viewed from the adjacent residences and park users (Figure 3.14-2a, Photo 4). Mature riparian vegetation lines the river throughout this levee reach.

The Sacramento River corridor creates a noticeable contrast to the surrounding, predominantly developed area. This portion of the river is highly utilized and enjoyed for its vegetation and wildlife, recreational opportunities, and high scenic quality. Most views from the river and shore are limited to the foreground by bends in the river, vegetation, and development. Large remnant patches of riparian vegetation line this stretch of river, enhancing the levee views of recreationists on the river (Figure 3.14-2a, Photo 5). The visual quality of the area is moderately unified because the landscape is fairly congruent and harmonious in terms of scale, color, and form. Development and other infrastructure preclude a highly unified visual landscape; they have affected the intactness and unity of the viewshed by encroaching on the river's floodplain and agricultural areas. The inherent scenic qualities presented by a naturalized, accessible river corridor in a highly developed area result in a vividness that is moderately high. The presence of development and infrastructure surrounding this corridor results in a study area that is moderate in intactness and unity.

Within this levee reach, expansive middleground and background views can be viewed only from atop the levee or from the upper floors of multi-story buildings in the commercial and industrial developments. Residences in this levee reach have foreground views of the levee and mature riparian trees, with very limited or no middleground and background views (Figure 3.14-2a, Photo 6). From atop the levee, foreground views to the east extend over the Sacramento River and riparian vegetation toward middleground views of the high-rise building of downtown Sacramento. Background views to the Sierra Nevada foothills to the east are rarer; views of the Vaca Mountains and the Coast Range are seen to the west more commonly, air quality permitting.

Sacramento River South Levee

The Sacramento River South Levee is located between the DWSC East Levee to the south and the Port South Levee to the north. Rural residences with large parcels of land typify this levee reach. The residences are commonly older, small, one-story residences and newer, larger, two-story residences that are scattered off South River Road and small, one-lane, rural roadways such as Davis Road and Linden Road. These homes often are far apart and are at a lower density than newer developments even where they are closer together (Figure 3.14-2b, Photo 1). These residences typically are surrounded by fencing and mature landscaping, including tall native and non-native trees. This landscaping distinguishes them from the surrounding open space agricultural fields and livestock grazing lands. Barns and corrals are commonly seen structures on rural residential land where owners keep horses and livestock. Additionally, pockets of shrubs, trees, and riparian vegetation located in swales and drainages create a noticeable contrast to the surrounding, predominantly low-lying grassland and agricultural vegetation. Riparian vegetation along the Sacramento River also can be viewed.

Newer suburban residences have been and are being built in areas directly adjacent to this levee reach in the northern portion and in other portions of West Sacramento at a much higher density

than in the past. These are one- and two-story homes with very little space between units. Because these areas are fairly new, they lack mature vegetation (Figure 3.14-2b, Photo 2). These developments alter the agrarian visual character of the study area to one visually analogous to newly developed areas elsewhere in the Sacramento metropolitan region.

The river corridor along this levee reach is also highly utilized and enjoyed for vegetation and wildlife, recreational opportunities, and high scenic quality. Most views from the river and shore are limited to the foreground by bends in the river, vegetation, and development. Large remnant patches of riparian vegetation line this stretch of river, enhancing the levee views of recreationists on the river. However, this reach also contains long stretches of levee denude of vegetation and lined with riprap, detracting from the scenic quality.

Within the study area, foreground views extend over agricultural fields and recent development toward background views of the Sierra Nevada foothills and Vaca Mountains. Downtown Sacramento can be seen in the middleground, distinguished by buildings rising above the tree line (Figure 3.14-2b, Photo 3). This contrast is particularly vivid seasonally, when autumn foliage contrasts with the plowed fields or when trees have gone dormant and shed their leaves, exposing more of the downtown Sacramento skyline.

Overall, the visual quality of the Sacramento River South Levee is moderately unified because the existing landscape is fairly congruent and harmonious in terms of scale, color, and form. The intrusions associated with newer residential development and other infrastructure preclude a highly unified visual landscape. These intrusions have affected the intactness and unity of the viewshed and have altered the pastoral character to one that is suburban. The presence of existing development and utility infrastructure results in a study area with moderate vividness, intactness, and unity.

Port North Levee

The Port North Levee is located between the DWSC West Levee to the west and the Sacramento River North Levee to the east and borders the Port of West Sacramento Turning Basin and ship lock. The Turning Basin divides the city into two distinct regions. The urban city core and industrial zone are located north of the Port North Levee, and the majority of the residential suburban development and all agricultural lands in the city are south of the Turning Basin. Large industrial and commercial developments are typical of this levee reach, with some residential development on the far eastern portion of this reach.

Industrial developments directly adjacent to the study area typically consist of large expanses of pavement or gravel, large warehouse-type buildings that are industrial looking and lack distinctive architectural style, and little to no vegetation (Figure 3.14-2c, Photo 1). These developments obstruct the middleground and background views from adjacent roadway travelers and residences.

Pockets of open space bordering the Turning Basin have mature native and non-native trees and are enjoyed for their scenic quality. The Turning Basin is highly utilized and enjoyed for its recreational opportunities and wildlife. Most views from the water and shore are limited to the foreground because they are obstructed by the levees, vegetation, and large industrial buildings.

Residences with views of the study area are located in the eastern portion of this levee reach and are older suburban developments. In some cases residences directly abut the levee (Figure 3.14-2c, Photo 2). These homes are commonly surrounded by fencing and mature landscaping, including tall

Photo 1. Looking north along South River Road. This photo depicts the southern portion of this levee reach and the lower density development typical of this area. Note the mature vegetation along the waterside and landside of this levee.

Photo 2. Looking northwest from South River Road. This photo depicts the high density residential development that is being built along the northern portion of this levee reach.

Figure 3.14-2b
Representative Photos of Program Area and Key Views

Photo 3. Looking northwest from South River Road. This photo depicts the typical rural character of the southern portion of this levee reach. Downtown Sacramento can be seen along the horizon line, distinguished by buildings rising above the tree line.

Figure 3.14-2b
Representative Photos of Program Area and Key Views

Photo 1. Looking west at the Port of West Sacramento. This photo depicts the industrial character of the port and the limited middleground and background views roadway travelers have.

Photo 2. Looking south at the residences abutting the eastern portion of this levee reach. Note the train cars and tracks separating the residences from accessing the water and the mature riparian vegetation beyond the tracks.

00875.07 EIS (7-09)

Figure 3.14-2c
Representative Photos of Program Area and Key Views

Photo 3. Looking east across the DWSC from the Port South Levee. This photo depicts the mature riparian vegetation that lines eastern portion of the Port North Levee.

00875.07 EIS (7-09)

Figure 3.14-2c
Representative Photos of Program Area and Key Views

native and non-native trees, even when located directly adjacent to a levee. Throughout this area, there are access locations where people can reach the river and use the levee crown for recreation. Residences in this levee reach have foreground views of the levee and mature riparian trees, with little to no middleground and background views (Figure 3.14-2c, Photo 3).

Within this levee reach, expansive middleground and background views can be viewed only from atop the levee or from within the commercial and industrial developments bordering the Turning Basin. Background views to the Sierra Nevada foothills to the east are rarer; views of the Vaca Mountains and the Coast Range to the west are more common, air quality permitting.

The visual quality of the Turning Basin itself and the views offered from it are moderate. Appealing views of the Yolo Bypass, surrounding open space, and West Sacramento and Sacramento cityscapes are limited by surrounding development and infrastructure, but present both rural and urban scenes that are attractive. Views from the Port North Levee are low to moderate in vividness. The artificial intrusions associated with the surrounding development and infrastructure are moderate to high, resulting in low to moderate intactness. The visual quality of the area is low in unification because the landscape is disjunctive in its abrupt changes in land use.

Port South Levee

The Port South Levee is located between the DWSC East Levee to the west and the Sacramento River South Levee to the east and borders the Turning Basin and ship lock. The Turning Basin divides the city into two distinct regions. The urban city core and industrial zone are located north of the Port South Levee, and the majority of the residential, suburban development and all agricultural lands in the city are south of the Turning Basin. Expanses of open space and undeveloped lands, and commercial developments, are typical of this levee reach, with some residential development on the far eastern portion.

Commercial developments directly adjacent to the study area typically consist of large expanses of pavement, large warehouse type buildings that are industrial looking and lack distinctive architectural style, and little to no vegetation (Figure 3.14-2d, Photo 1). These developments obstruct the middleground and background views for adjacent roadway travelers. The area's infrastructure has already been completed (e.g. roadways, street lighting, etc.), but the majority of the parcels are still void of buildings.

Shoreline recreation occurs throughout this levee reach. A gravel road bordering the Turning Basin is accessible from Lake Washington Boulevard and Jefferson Boulevard. A parking facility and hand-carry boat launch is also accessible from Jefferson Boulevard at South River Road. Recreationists are the primary viewers of this levee reach. Mature native and non-native trees are located on the eastern end of this levee reach, with few large trees in the remaining reach. The Turning Basin is highly utilized and enjoyed for its recreational opportunities and wildlife. Most views from the water and shore are limited to the foreground because they are obstructed by the levees, vegetation, and large industrial buildings. Views from the levee and adjacent open space are expansive in all directions.

Residences with views of the study area are located in the eastern portion of this levee reach and are newer suburban developments. A large swath of open space and undeveloped land separates the residences from the levee and study area (Figure 3.14-2d, Photo 2). These homes are being built at a much higher density than in the past. Typically they are one and two-story homes with very little space between units. Because these areas are fairly new, they lack mature vegetation. These

developments alter the agrarian visual character of the southern city to one visually analogous to newly developed areas elsewhere in the Sacramento metropolitan region. Throughout this area, there are locations where people can access the river and use the levee crown for recreation.

Within this levee reach, expansive middleground and background views exist from the majority of the study area. From atop the levee, foreground views to the east extend over open space and undeveloped lands toward middleground views of the high-rise buildings of downtown Sacramento (Figure 3.14-2d, Photo 3). Background views to the Sierra Nevada foothills to the east are rarer; views of the Vaca Mountains and the Coast Range to the west are more common (Figure 3.14-2d, Photo 4), air quality permitting.

While the visual quality of the Turning Basin itself is moderate, the views offered from it are of moderately high quality. Appealing views of the Yolo Bypass, surrounding open space, and West Sacramento and Sacramento cityscapes present both rural and urban scenes that are attractive. Views from the Port South Levee are moderate in vividness. The artificial intrusions associated with the surrounding development and infrastructure are moderate, resulting in moderate intactness. The visual quality of the area is also moderate in unification because the landscape is disjunctive in its abrupt changes in land use.

South Cross Levee

The South Cross Levee is located between the DWSC East Levee to the west and the Sacramento River South Levee to the east. Rural residences with large parcels of land typify this levee reach. The residences are commonly older, small, one-story residences and newer, larger, two-story residences that are scattered off Jefferson Boulevard, South River Road, and small one-lane, rural roadways such as Burrows Avenue. These homes are often located far apart, and are at a lower density than newer developments even where they are closer together (Figure 3.14-2e, Photo 1). These residences typically are surrounded by fencing and mature landscaping, including tall native and non-native trees. This landscaping distinguishes them from the surrounding open space agricultural fields and livestock grazing lands. Barns and corrals are commonly seen structures on rural residential land where owners keep horses and livestock. Additionally, pockets of shrubs, trees, and riparian vegetation located in swales and drainages create a noticeable contrast to the surrounding predominantly low-lying grassland and agricultural vegetation.

In this levee reach, foreground views extend over agricultural fields and rural residences toward background views of the Sierra Nevada foothills and Vaca Mountains (Figure 3.14-2e, Photo 2). Downtown Sacramento can be seen in the middleground, northeast of the study area, distinguished by buildings rising above the tree line (Figure 3.14-2e, Photo3).

Overall, the visual quality of the South Cross Levee is moderately unified because the existing landscape is fairly congruent and harmonious in terms of scale, color, and form. The intrusions associated with residential development and other infrastructure preclude a highly unified visual landscape. These intrusions have affected the intactness and unity of the viewshed. The presence of existing development and utility infrastructure results in a study area with moderate vividness, intactness, and unity.

Deep Water Ship Channel West Levee

The DWSC West Levee is located between the Yolo Bypass Levee reach and convergence of the DWSC with the Sacramento River and serves as an eastern boundary to the Yolo Bypass. Land uses

Photo 1. Looking northeast at the commercial developments adjacent to this levee reach. Note the lack of mature vegetation and limited middleground and background views.

Photo 2. Looking southwest from the Port South Levee across the northern spur of Lake Washington. This photo depicts the open space and undeveloped land separating the project area and new suburban development to the south.

Figure 3.14-2e
Representative Photos of Program Area and Key Views

within the bypass are primarily agricultural or other open space uses that are compatible with flood control operations (Figure 3.14-2f, Photo 1). Agricultural production is limited to field and row crops. During periods of high flows in the Sacramento River, the bypass may be filled with water. Views from the bypass are expansive when haze is at a minimum. For the northernmost 0.5 mile of levee reach, views from the levee to the east extend over open space and new residential developments in the foreground and middleground, while typical views from the levee to the west, north, and south in this levee reach extend over agricultural fields and open space in the foreground to the middleground and background. The remainder of this levee reach, south of the more developed city, contains sweeping views from atop the levee in all directions over agricultural fields, rural residences, and open space in the foreground to the middleground and background. Views from the water and shore are limited by the levees. Only scattered trees exist through the majority of this levee reach, with the exception of the southernmost 9 miles which contain riparian vegetation and mature trees which enhance the scenic quality. Views of the Sierra Nevada foothills to the east are occasionally available on clear days. Expansive views to the west highlight the Vaca Mountains and Coastal Range. These types of landscape views are strongly characteristic of the Sacramento Valley and have contributed to the region's identity.

Buildings associated with farms and duck clubs are commonly raised structures that can withstand flooding. These structures are scattered throughout the bypass. Most of the bypass is kept free of shrubs and trees, except for along the toe drains adjacent to the levees, where riparian vegetation lines the water corridor.

The visual character of the DWSC Levee reach is an appealing and sharp contrast against the Sacramento metropolitan region. Views are moderately high in vividness. The artificial intrusions associated with development, agriculture, and infrastructure are low, but present, resulting in moderate intactness. The visual quality of the area is also moderately high in unification because the landscape is fairly congruent and harmonious in terms of scale, color, and form.

Deep Water Ship Channel East Levee

The DWSC East Levee is located between the Port South Levee reach and the South Cross Canal and serves as a western boundary to the city. Land uses in the city adjacent to this levee reach are primarily newer suburban developments to the north and open space and agricultural production to the south. Although many areas along the levees remain in agricultural production, there has been and continues to be increasing conversion of agricultural land to residential uses. This area is developing in a pattern similar to other cities, radiating out from the larger urban core of the city and spreading southward where vast acreage of agricultural land remains.

The southern portion of the city is planted with predominantly row and field crops or used for livestock grazing (Figure 13.4-2g, Photo 1). A patchwork of agricultural lands and urban development separates this agricultural land from developed areas to the north. When valley haze is at a minimum, there are expansive views of agricultural lands, urban development, and mountains across these fields. Middleground views include the city of Sacramento, distinguished by buildings rising above the tree line, development, or agricultural fields (Figure 3.14-2g, Photo 2). Views from the water and shore are limited by the levees. Scattered trees growing on the levee and along the shore exist throughout this levee reach and add character to foreground views. Background views of the Sierra Nevada foothills and Vaca Mountains occur to the east and west, respectively. These types of landscape views are strongly characteristic of Sacramento and have contributed to the region's identity.

Newer residential development in the northern portion of this levee reach tend to be homogenous in nature, having similar architectural styles, building materials, and plan layouts. This development often lacks a distinctive character from one community to the next. Suburban residences have been constructed at a high density. Typically, these residences are two-story homes with very little space between units (Figure 3.14-2g, Photo 3). Because these residential developments are fairly new, they lack mature vegetation. The density of newer development precludes views beyond the interior of the development, except for residences on the outskirts of the development. These residences have views over the open space as described above. The residences directly adjacent to the levee have unobstructed views from the upper story only.

The visual character of the DWSC East Levee is an appealing and sharp contrast to the city and Sacramento metropolitan region. Views are moderately high in vividness. The artificial intrusions associated with development, agriculture, and infrastructure are moderate to the east, resulting in low to moderate intactness. The visual quality of the area is moderately high in unification because the landscape is fairly congruent and harmonious in terms of scale, color, and form.

Yolo Bypass Levee

The Yolo Bypass Levee is located between the Sacramento Bypass and the DWSC and serves as a western boundary to the city. Land uses within the bypass are primarily agricultural or other open space uses that are compatible with flood control operations (Figure 3.14-2h, Photo 1). Agricultural production is limited to field and row crops. During periods of high flows in the Sacramento River, the bypass may be filled with water. Views from the bypass are expansive when haze is at a minimum. Typical views to the west, north, and south extend over agricultural fields in the foreground to the middleground and background. Views to the east extend over the CHP Academy and industrial portions of the city in the foreground to views of downtown Sacramento in the middleground and background (Figure 3.14-2h, Photo 2 and Photo 3). Most viewers cross the bypass on I-80. The crossing is elevated and crosses the bypass in an east-west orientation. Crossing the bypass from west to east, the high-rise buildings of downtown Sacramento can be seen in the middleground and background, with views of the Sierra Nevada foothills occasionally available on clear days. Crossing from east to west provides views of the western portion of the Sacramento Valley and the Vaca Mountains. These types of landscape views are strongly characteristic of the Sacramento Valley and have contributed to the region's identity.

Buildings associated with farms and duck clubs are commonly raised structures that can withstand flooding. These structures are scattered throughout the bypass. Most of the bypass is kept free of shrubs and trees, except for along the toe drains adjacent to the levees, where riparian vegetation lines the water corridor (Figure 3.14-2h, Photo 4).

The visual character of the bypass is an appealing and sharp contrast to the city and Sacramento metropolitan region. Appealing views of the bypass and Sacramento cityscape present both rural and urban scenes that are attractive. Views are moderately high in vividness. The artificial intrusions associated with development, agriculture, and infrastructure are low, but present, resulting in moderate intactness. The visual quality of the area is also moderately high in unification because the landscape is fairly congruent and harmonious in terms of scale, color, and form.

Sacramento Bypass Levee

The Sacramento Bypass consists primarily of open space and flood conveyance land uses (Figure 3.14-2i, Photo 1). No development or agricultural activities occur within the bypass.

Photo 1. Looking southwest from atop the DWSC East Levee (outside of the project area) toward mature riparian vegetation along the southern most portion of the DWSC West Levee.

Photo 4. Looking west from atop the Yolo Bypass Levee. This photo depicts the riparian vegetation and mature trees that line the toe drain adjacent to this levee reach.

00875.07 EIS (7-09)

Figure 3.14-2h
Representative Photos of Program Area and Key Views

Agricultural land, planted with row crops, borders the Sacramento Bypass to the north, southwest, and west. The Sacramento River serves as its eastern boundary, and the CHP Academy and industrial land uses are located to the south. While few activities take place within the bypass (i.e., hunting occurs during the appropriate seasons), its levees are used for recreation.

Viewers using the levees of the bypass have expansive views that, when haze is at a minimum, extend over agricultural fields in the foreground to the middleground and background. The high-rise buildings of downtown Sacramento can be seen in the middleground, rising up above the tree line. Background views to the Sierra Nevada foothills to the east are rarer, while views of the Sutter Buttes to the north are more common (Figure 3.14-2i, Photo 2). Some views are obscured by vegetation along the levees of the bypass and the CHP Academy, limited in certain directions to the foreground, depending on the viewer's location (Figure 3.14-2i, Photo 3). Views also differ seasonally, offering more or fewer views when vegetation is dormant or in leaf.

While the visual quality of the bypass itself is moderate, the views offered from it are moderately high. Appealing views of the bypass and Sacramento cityscape present both rural and urban scenes that are attractive. Views from the Sacramento Bypass levees are moderately high in vividness. The artificial intrusions associated with the surrounding development and infrastructure are moderate, resulting in moderate intactness. The visual quality of the area is also moderate in unification because the landscape is disjunctive in its abrupt changes in land use.

3.14.3 Environmental Consequences

This section describes the visual resource effects associated with the proposed program. It describes the methods used to determine the effects of the program and lists the thresholds used to conclude whether an effect would be significant. Measures to mitigate (i.e., avoid, minimize, rectify, reduce, eliminate, or compensate for) significant effects accompany each effect discussion.

3.14.3.1 Assessment Methods

Using the concepts and terminology described at the beginning of this section, and the criteria for determining effects, the analysis of visual effects of the program is based on:

- direct field observation from vantage points, including neighboring buildings, property, and roadways (conducted November 28, 2007 and February 5, 2009);
- photographic documentation of key views of and from the program reaches taken on November 29, 2007 and February 5, 2009, as well as regional visual context;
- review of project construction drawings; and
- review of the program in regard to compliance with state and local ordinances and regulations and professional standards pertaining to visual quality.

3.14.3.2 Determination of Effects

For this analysis, an effect pertaining to visual resources was considered significant if it would result in any of the following environmental effects, which are based on professional practice and State CEQA Guidelines Appendix G (14 CCR 15000 *et seq*.):

- cause a substantial, demonstrable negative aesthetic effect on a scenic vista or view open to the public;
- substantially damage scenic resources, including, but not limited to, trees, rock outcroppings, and historic buildings within a state scenic highway;
- substantially degrade the existing visual character or quality of the site and its surroundings; or
- create a new source of substantial light or glare that would adversely affect day or nighttime public views.

3.14.3.2.1 Professional Standards

According to professional standards, a project may be considered to have a significant effect if it would:

- conflict with local guidelines or goals related to visual quality;
- alter the existing natural viewsheds, including changes in natural terrain;
- alter the existing visual quality of the region or eliminate visual resources;
- increase light and glare in the project vicinity;
- result in backscatter light into the nighttime sky;
- result in a reduction of sunlight or introduction of shadows in community areas;
- obstruct or permanently reduce visually important features; or
- result in long-term (that is, persisting for 2 years or more) significant visual changes or contrasts to the existing landscape as viewed from areas with high visual sensitivity.

3.14.3.3 Effects and Mitigation Measures

3.14.3.3.1 No Action Alternative

To summarize from Chapter 2, Alternatives, the No Action Alternative is the continuation of the existing deficiencies along the nine levee reaches and absence of levee alternatives to increase the level of protection. Current levee operations and maintenance activities would continue. No potential construction-related effects on visual resources would occur.

In terms of the potential for urbanization and development to be restricted without the program, visual resources are expected to remain similar to existing conditions with the exception of the southern portion of the city. The visual character of the southern city may or may not continue to change as rural and agricultural lands are converted to commercial and residential uses. The visual character of other areas is not expected to substantially change because the areas are generally built out, such as the Port and the Broderick/Bryte and Washington areas, or are dedicated for open space or flood control purposes, such as Sacramento and Yolo Bypasses. Other flood control projects may be implemented, adjacent to locations that fall within the proposed program, and would change the visual character of levees surrounding the city as vegetation is removed to comply with USACE levee vegetation guidance.

Without levee improvements, there is the continued risk of levee failure. A catastrophic levee failure would result in flooding and inundation that could significantly damage existing visual resources

Photo 1. Looking northeast at the Sacramento Weir from within the Sacramento Bypass. Trees along the horizon are on the opposite bank of the Sacramento River, across from the weir.

Photo 2. Looking west along the Sacramento Bypass Levee. This photo depicts background views of the Coast Range, faintly visible on the horizon line.

Figure 3.14-2i
Representative Photos of Program Area and Key Views

(such as vegetation). Flood-fight or cleanup activities could present new visual elements similar to those identified below during project construction. In addition, scenic vistas for existing and future recreation facilities could be damaged irreparably or for an extended period of time which would reduce the enjoyment derived by recreationists. Given the uncertainty of the occurrence or magnitude of such an event, potential effects on recreation cannot be quantified based on available information.

In its levee vegetation guidance, USACE has established a woody vegetation-free zone required for operations and maintenance of Federal project levees. Woody vegetation has been allowed to persist within the study area and more broadly throughout the SRFCP in part to provide for the functions and values attributed to riparian vegetation. However, in light of recent levee failures and flooding disasters in the United States (e.g., the flooding related to Hurricanes Katrina and Rita), compliance with the vegetation-free zone will be more strictly adhered to and enforced.

Compliance with the levee vegetation guidance could result in the removal of a substantial amount of vegetation, which would substantially comprise the character and quality of the visual resources in the waterway corridors around the city. Many visual receptors, including pedestrians, bicyclists, equestrians, boaters, and viewers from both sides of the water course are accustomed to the visual character that vegetation contributes to the landscape. Removal of a substantial amount of this riparian vegetation in compliance with the levee vegetation guidance would significantly affect recreation in the program area, similar to Effect VIS-1 described below.

But for areas where a setback levee is proposed, which may allow existing vegetation to be preserved, or where the vegetation is found to be in compliance with USACE levee vegetation guidance, the No Action Alternative and flood and recreation program alternatives could result in effects on riparian vegetation and visual resources that are comparatively similar. However, absent a site-specific study of the application of the USACE levee vegetation guidance, calculation of the magnitude and significance of effects is too speculative based on available information.

3.14.3.3.2 Flood and Recreation Program Alternatives

Effect VIS-1: Affect a Scenic Vista

The study area is not located within a designated scenic vista. However, major roads leading into West Sacramento and downtown Sacramento act as gateways and offer unique vistas of the contrasting landscape features. High rise buildings that tower over agriculture fields and residential development are softened by the lush riparian corridors that line our waterways. This is most evident while traveling eastbound on I-80 across the Yolo Bypass, but local roads such as River Road and Jefferson Boulevard offer the same experience. Program construction and the current USACE levee maintenance policy would require the removal of riparian vegetation (see Effect VIS-4). Without the vegetation buffer, high rise and large industrial buildings would contrast sharply with other landscape features and reduce the quality of the scenic vistas and gateways. Therefore, the proposed program would have a significant effect on undesignated scenic vistas. Because vegetation in many areas would not be allowed to be replanted (see Effect VIS-5), no feasible mitigation is available to reduce the effect to a less-than-significant level. This effect therefore would be significant and unavoidable.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall	▪ Seepage berm
	▪ Levee raise (in place)	▪ Sheet pile wall
	▪ Levee raise (adjacent)	▪ Slurry cutoff wall
	▪ Levee raise (full)	▪ Slope flattening
	▪ Closure structure	▪ Stability berm
	▪ Interior drain	▪ Rock slope protection
	▪ Jet grouting	▪ Setback levee
	▪ Relief wells	▪ Vegetation removal
Recreation	▪ Trails	▪ Developed water access
	▪ Riverside parks	▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect would occur in all nine program reaches.

Effect VIS-1 Finding	With Mitigation
Significant	Significant and unavoidable; no feasible mitigation

Effect VIS-2: Create a New Source of Light or Glare

The program would not add any new permanent source of light or glare. During levee treatment construction, it is expected that some alternatives would be constructed at night, requiring temporary nighttime lighting. Equipment staging areas also would be lit at night for security reasons. Such nighttime lighting would be temporary through the duration of construction. There are many residences on the landside of the levee, within close proximity to the proposed program area. This effect would be significant because some residences would have direct views of the construction adjacent to their homes and to the nighttime lighting associated with the levee alternatives. This would significantly affect their viewshed as these residences are not accustomed to nighttime glare of this degree. This effect would be significant and unavoidable.

Because this effect is significant and unavoidable, those directly affected by this effect would be relocated. As part of the environmental commitment described in Section 2.9, Chapter 2, Alternatives, WSAFCA would provide assistance for residents who are required to relocate during the construction period. WSAFCA would compensate residents for reasonable rent and living expenses incurred due to relocation. Residents would have the right to decent, safe and sanitary housing in accordance with the Uniform Act.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall ▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Closure structure ▪ Interior drain ▪ Jet grouting ▪ Relief wells	▪ Seepage berm ▪ Sheet pile wall ▪ Slurry cutoff wall ▪ Slope flattening ▪ Stability berm ▪ Rock slope protection ▪ Setback levee
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect would occur in all nine program reaches.

Effect VIS-2 Finding	With Mitigation
Significant	Significant and unavoidable; no feasible mitigation

Effect VIS-3: Affect Scenic Resources along a Designated Scenic Highway

No Federal, state, or locally designated scenic roadways are located within the study area. No effects on scenic resources along a scenic highway would occur. No mitigation is necessary.

Effect VIS-3 Finding	With Mitigation
No effect	N/A

Effect VIS-4: Cause Temporary Visual Effects as a Result of Construction Activities

Construction activities would introduce considerable heavy equipment and associated vehicles, including dozers, graders, cranes, scrapers, and trucks into the views of adjacent residents, recreationists, motorists, and businesses. The equipment would be visible throughout the construction season. Presence of the equipment would temporarily degrade the visual quality of the study area to low vividness, intactness, and unity.

Residential viewer groups in the study area and vicinity are not accustomed to seeing construction activities and equipment, and sensitivity to such effects would be high. Other viewer groups are more accustomed to seeing construction activities and equipment from construction that has occurred in the business parks near the I Street Bridge, daily activities in the industrial areas, and local roadway construction projects and would have low sensitivity to construction effects.

However, because this effect is temporary, would last no longer than the construction duration, and is limited to small portions of the larger river corridor, it would not substantially degrade the visual quality of the study area. In addition, the implementation of an environmental commitment to provide temporary construction barriers, as needed, between construction zones and residences, as described in Section 2.9 of Chapter 2, Alternatives, would make this effect less than significant.

In addition, effects on roadway users would be less than significant because of the short intervals of time that they are in visual contact with the program reaches and familiarity with construction along other roadways in the vicinity.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall	▪ Seepage berm
	▪ Levee raise (in place)	▪ Sheet pile wall
	▪ Levee raise (adjacent)	▪ Slurry cutoff wall
	▪ Levee raise (full)	▪ Slope flattening
	▪ Closure structure	▪ Stability berm
	▪ Interior drain	▪ Rock slope protection
	▪ Jet grouting	▪ Setback levee
	▪ Relief wells	▪ Vegetation removal
Recreation	▪ Trails	▪ Developed water access
	▪ Riverside parks	▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect would occur in all nine program reaches.

Effect VIS-4 Finding	With Mitigation
Less than significant	N/A

Effect VIS-5: Affect the Existing Visual Character or Quality of the Site and Its Surroundings as a Result of Construction, Operations, and Maintenance

Construction of flood program alternatives has the potential to substantially degrade the existing visual character or quality of the sites and surroundings for viewer groups for two reasons: 1) a new levee embankment or flood structure (e.g., flood wall, adjacent levee raise, setback levee) would be present, and 2) construction would require the removal of all vegetation within the construction footprint and within established operations and maintenance vegetation-free zones according to USACE policies. This would mainly affect the levee crown, the landside and waterside levee slopes, and 15 feet from the toe on both sides.

Depending on location and existing conditions, the addition of flood structures could degrade the visual character of the area and obstruct views. For example, a flood wall constructed along the

DWSC West or Port North or South Levee reaches could obstruct views of the DWSC and Barge Canal and change the quality of the visual character of these areas. Since the locations of flood alternatives are not fully developed at this time, a definitive determination is not possible until project level plans are fully developed. However, flood alternatives have the potential of causing a significant and potentially unavoidable effect.

Construction of flood alternatives would require compliance with recent USACE policies regarding woody vegetation on levees. This policy requires that all woody vegetation within the levee prism must be removed and the levee slope maintained free of woody vegetation. The levee slopes would be required to be maintained free of woody vegetation in perpetuity, resulting in the loss of a highly valued, regional aesthetic landscape component. Trees and vegetation located outside of the levee prism, construction footprint, and maintenance zone would remain to the extent possible and retain the high visual quality. This would be evident in areas where the levee is wider and the majority of the vegetation is located directly adjacent to the river outside of the levee prism. The mature vegetation along the levees is characteristic of the region and is a striking, distinctive element in the landscape. The existing vegetation that is removed will be replaced with herbaceous vegetation. An environmental commitment has been made by WSAFCA to minimize vegetation removal to the extent possible (Section 2.9, Chapter 2, Alternatives); however, maintaining the levees void of the characteristic riparian vegetation and mature landscaping would highly degrade the visual character and quality of the area for all viewer groups. No feasible mitigation is available to reduce the effect. This effect would be significant and unavoidable.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall	▪ Seepage berm
	▪ Levee raise (in place)	▪ Sheet pile wall
	▪ Levee raise (adjacent)	▪ Slurry cutoff wall
	▪ Levee raise (full)	▪ Slope flattening
	▪ Closure structure	▪ Stability berm
	▪ Interior drain	▪ Rock slope protection
	▪ Jet grouting	▪ Setback levee
	▪ Relief wells	▪ Vegetation removal

Affected Reaches

Although different flood program alternatives are proposed for the reaches, this effect would occur in all nine program reaches.

Effect VIS-5 Finding	With Mitigation
Significant	Significant and unavoidable; no feasible mitigation

Effect VIS-6: Conflict with Local Visual Resource Policies

As mentioned above under the local regulatory policies, the majority of the local jurisdictions have tree preservation ordinances and riverfront master plans where riparian vegetation and mature landscaping are highly desirable components that are greatly valued for the aesthetic qualities they provide. Construction of the new levee embankment would require the removal of all vegetation within the construction footprint and all woody vegetation within the levee prism. This removal of vegetation would conflict with local visual policies. Because vegetation in many areas would not be allowed to be replanted, as discussed in Effect VIS-5, no feasible mitigation is available to reduce the effect. This effect would be significant and unavoidable.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause this effect:

Program	Alternative	
Flood	▪ Flood wall ▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Closure structure ▪ Interior drain ▪ Jet grouting ▪ Relief wells	▪ Seepage berm ▪ Sheet pile wall ▪ Slurry cutoff wall ▪ Slope flattening ▪ Stability berm ▪ Rock slope protection ▪ Setback levee ▪ Vegetation removal
Recreation	▪ Developed water access	

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, this effect would occur in all nine program reaches.

Effect VIS-6 Finding	With Mitigation
Significant	Significant and unavoidable; no feasible mitigation

Section 3.15
Recreation

3.15.1 Introduction

This section describes the regulatory and environmental setting for recreation, effects on recreation facilities and recreation opportunities that would result from the program, and the mitigation measures that would reduce significant effects.

The key sources of data and information used in the preparation of this section are listed below

- *West Sacramento General Plan*, (City of Sacramento 1990, last amended 2004)
- *City of West Sacramento Parks Master Plan (Smith Group 2003)*
- *Sacramento Riverfront Master Plan*, July 2003
- Dave Shpak, Park Development Manager, City of West Sacramento
- Southport Design Guidelines, April, 1996, last amended November 2005
- *Triangle Specific Plan*, Volume 1, June 1993
- *Washington Specific Plan,* May 1996
- *West Sacramento Bicycle and Pedestrian Path Master Plan*, October 1991and 1995 Addendum
- *Yolo Bypass Wildlife Area Land Management Plan*, June 2008
- *Yolo County General Plan*, July 1983, Open Space and Recreation Element last amended November 2002

3.15.2 Affected Environment

3.15.2.1 Regulatory Setting

3.15.2.1.1 Federal and State

No Federal or state plans, policies, regulations, or laws related to recreation resources apply to the proposed program.

3.15.2.1.2 Local

Broderick Boat Ramp Grant Contract

The City of West Sacramento operates the Broderick Boat Ramp, located along the North Sacramento River levee, under a grant agreement with the Department of Boating and Waterways. This agreement, approved on March 23, 2006, stipulates that the City must obtain prior approval from the Department of Boating and Waterways before closing the boat ramp to public access for any length of time (City of West Sacramento Housing & Community Investment 2006).

City of West Sacramento General Plan

The *West Sacramento General Plan* (City of West Sacramento 1990) identifies the following goals, objectives and policies for the implementation plan.

Recreation and Cultural Resources

- **Goal A:** To establish and maintain a public park system and recreation facilities suited to the needs of West Sacramento residents and visitors.
    - **Policy A12:** The City shall identify appropriate open spaces, including areas within the Central Business District and along the Sacramento River, for development of safe community activity areas.
- **Goal B:** To promote the provision of private recreation facilities and opportunities.
    - **Policy B6:** The City supports the use of the barge canal for aquatic recreational activities, such as sailing, rowing, kayaking, and canoeing, and supports the establishment of a multi-use aquatic facility along the barge canal. Aquatic parks, boat houses, docks, and other support facilities for boating shall be deemed compatible uses along the Deep Water Ship Channel and the barge canal within all land use designations.
- **Goal D:** To provide and encourage, to the fullest extent possible, public access to the Sacramento River and Deep Water Ship Channel for recreation purposes.
    - **Policy D1:** The City shall ensure continuous public access to the Sacramento River for its full length within West Sacramento.
    - **Policy D2:** The City shall seek to ensure continuous public access to the Deep Water Ship Channel, within the limits imposed by safety considerations.
    - **Policy D3:** Linear access to the Sacramento River and Deep Water Ship Channel shall be linked to the city's overall system of parks, recreational pathways, and open space.
    - **Policy D4:** The city shall encourage the development of public and private marinas in appropriate locations on the Sacramento River and along the Deep Water Ship Channel. Siting and development of marinas shall avoid, as much as possible, areas of significant existing riparian vegetation.
    - **Policy D5:** The City shall support and encourage the development of public and private water-oriented park and recreation facilities along the Sacramento River and the Deep Water Ship Channel.
- **Goal E:** To provide a network of pedestrian and bicycle pathways connecting parks and open space areas with other destination points within and beyond the city of West Sacramento.
    - **Policy E2:** The City shall implement a *Riverfront Park Master Plan* that provides for a system of continuous pedestrian and bicycle pathways along the Sacramento River.
    - **Policy E4:** The City shall coordinate the development of the riverfront as envisioned in the 1997 *Sacramento Greenway Plan*.

Natural Resources

- **Goal C:** To protect sensitive native vegetation and wildlife communities and habitat in West Sacramento.

- **Policy C5:** To minimize disturbance to wildlife, the City shall require the provision and maintenance of an adequate setback between significant wetland habitat and adjacent development. The buffer shall be landscaped with native or compatible introduced ornamental vegetation and may be used for passive recreation purposes.
- **Policy C12:** Public access and recreation facilities shall not eliminate or degrade riparian habitat values. Trails, picnic areas, and other developments shall be sited to minimize effects on sensitive wildlife habitat or riparian vegetation.

Transportation and Circulation

- **Goal G:** To promote pedestrian and bicycle travel as alternatives to automobile use.
  - **Policy G7:** To the extent practicable, bicycle and pedestrian pathways shall be included within open space areas and adjacent to waterways.

Urban Structure and Design

- **Goal B:** To enhance the relationship between the City and the Sacramento River.
  - **Policy B2:** The City shall protect and enhance public access to the Sacramento River along the entire riverfront within West Sacramento by providing for development of a continuous pedestrian and bicycle path along the river.
  - **Policy B4:** The City shall promote the development of important visual and scenic areas along the riverfront, including around the barge canal, for public access, including water-related activities.
  - **Policy B5:** The City shall promote and enhance open space and pedestrian links between the river and public schools, parks, and other major open space areas.

City of West Sacramento Parks Master Plan

The *West Sacramento Parks Master Plan* (Parks Master Plan) (Smith Group 2003) outlines the City's goals and policies with regard to the provision of parks and related recreation facilities for West Sacramento residents, and provides an inventory of current and proposed facilities.

As of April 2009, the City oversaw approximately 145 acres of developed parkland (City of West Sacramento 2009a). Based on the 2007 population of 44,928 (California Department of Finance 2007). This represents an 80-acre shortfall from the standard of 5 acres per 1,000 residents established in the General Plan. Based on this ratio, it is estimated that by 2025 population growth in West Sacramento would require the City to have a total of 375 acres of parkland available in order to meet this standard.

The Parks Master Plan lists underutilized assets, including the Sacramento River, DWSC, turning basin, barge canal, natural corridors, and riparian forests that are key opportunities for recreation development and protection. Several areas are targeted as particularly well-suited for park development. Construction of recreation facilities along the study area is proposed as follows:

- **Sacramento River North Levee:** Governors Residence State Park (now the site of the future California Indian Heritage Center), Sacramento River/Barge Canal recreation corridor (entire length of levee reach), Triangle Park Blocks neighborhood park, Stone Lock District, and seven fishing piers.

- **Port North Levee:** Stone Lock District and Sacramento River/Barge Canal recreation corridor.
- **Port South Levee:** Stone Lock District and Sacramento River/Barge Canal recreation corridor.
- **DWSC East Levee:** DWSC recreation corridor (entire length of levee reach).
- **South Cross Levee:** DWSC recreation corridor (entire length of levee reach).
- **Sacramento River South Levee:** Sacramento River/Barge Canal recreation corridor (entire length of levee reach), Stone Lock District, Southport neighborhood park, Southport community park (now called River Community Park), and Southport swim/gym.

Sacramento Riverfront Master Plan

The *Sacramento Riverfront Master Plan* (SRMP) is a collaborative planning document developed by the Cities of Sacramento and West Sacramento along with Yolo and Sacramento Counties and used to guide riverfront development along the Sacramento River. The SRMP places emphasis on improved public open space along the riverfront and enhancement and preservation of riverine, riparian, and upland forest environments to provide a richer experience for the user. Proposed future projects are grouped by implementation time frame from 0 to 16+ years and include extending riverfront trails, completing and constructing riverfront promenades, E Street fishing pier and boat dock, the Stone Lock District, and four non-vehicular bridges across the Sacramento River (Wallace Roberts and Todd 2003).

Solano County General Plan

The *Solano County General Plan* (Solano County Planning Commission 2008) identifies the following goals and policies for the implementation plan:

Resources

Goal RS.G-4: Preserve, conserve, and enhance valuable open space lands that provide wildlife habitat; conserve natural and visual resources; convey cultural identity; and improve public safety.

Sacramento–San Joaquin Delta Policies

Policy RS.P-26: Promote continued recreational use of the land and waters of the Delta, including fishing and boating; ensure needed recreation facilities are constructed, maintained, and supervised; protect landowners from unauthorized recreational uses on private lands; and maximize dwindling public funds for recreation by promoting public private partnerships and multiple uses of Delta lands consistent with the Land Use and Resource Management Plan for the Primary Zone of the Delta.

Recreational Resources

Policy RS.P-42: Encourage the use of existing natural and human-made corridors such as creeks, railroad rights-of-way, and corridors when creating future bike path and trail alignments.

Solano County Park and Recreation Element

Objective 3: Identify, preserve, and manage significant regional recreation and natural areas.

Policy C: The County shall work to protect identified recreation sites and natural resource areas.

Southport Design Guidelines

The Southport Design Guidelines are a component of the overall *Southport Framework Plan* that provides a detailed community concept and design guidelines for development in the Southport area. The community concept is based on a network of pedestrian-friendly villages that offer convenient walking and biking options. In the study area, the community concept includes a marina village connecting to the Sacramento River for water-oriented recreation and boating, a water-oriented community park adjacent to the Sacramento River, and improvements to levee trails along the Sacramento River and DWSC for increased pedestrian, bicycle, and equestrian recreation (City of West Sacramento Planning Department 1996).

Triangle Specific Plan

The *Triangle Specific Plan* (Zimmer Gunsul Frasca 1993) is a comprehensive planning document used to guide development within the "Triangle" area of West Sacramento, now referred to as the Bridge District. The Bridge District is bounded by SR 275, Business 80, and the Sacramento River and includes a small parcel south of Business 80. The Specific Plan has guidelines for using open space corridors and park streets for visual and physical connection to the river and identifies the following policies and guidelines for the waterfront.

Policy 1: The City will provide and encourage continuous public access to the entire length of the Sacramento River waterfront.

Policy 2: The City will establish and maintain a waterfront pathway and river access system as a component of the City's public park system and recreation facilities, suited to the needs of West Sacramento residents and visitors.

Policy 3: The City will promote complementary private development, open space and other facilities and opportunities consistent with public enjoyment of the waterfront during the day and in the evening, seven days a week.

Guideline—Riverfront Parks: Access will be limited to narrow foot trails at select locations. Access through Habitat Zones will not be provided with the exception of pedestrian access trails. Clearing for construction of the pedestrian access trails and placement of utilities shall be limited to the immediate construction corridor. Portions of the riparian habitat outside the immediate construction corridor shall not be cleared, and erosion control measures shall be implemented. Riverfront parks will include terraced steps for informal gathering spaces and an amphitheater zone.

Guideline—Establish a Special Place at the Water's Edge: Create places for public gatherings and contact with the river. Develop areas to allow for flexibility in use and function. Configure pathways on the river bank to create large islands of vegetation and design them to provide cover for a variety of birds, insects and small mammals.

Recreation components of the Specific Plan include the River Walk Promenade, three neighborhood parks, and distributed recreational features. The Promenade will be the focal point of the Bridge District, providing an inviting, attractive multi-purpose venue for waterfront access, bicycle and pedestrian travel, passive recreation, and civic celebrations. At buildout, improvements will consist of a levee-top promenade, terraced waterfront pathways, pier overlooks, on-water gangway and dock, and a central event plaza.

Washington Specific Plan

The *Washington Specific Plan* defines a vision for the future of the Washington Plan Area, a 194-acre urban area near the northeast corner of the city. It is bounded by Tower Bridge Gateway on the south, the Sacramento River on the east, A Street on the north, and portions of 6th and 8th Streets on the west. The *Washington Specific Plan* defines a "Riverfront Special Design District" with recommendations for parks and open space development along the Sacramento River.

The *Washington Specific Plan's* urban design guidelines (Chapter VII) identify taking advantage of the recreational open space and park opportunities along the riverfront as a primary and essential step in redeveloping the Washington area. The Riverfront Park and Trail System is proposed to meet that goal and to take advantage of the riverfront's river views, riparian woodland, vistas of downtown Sacramento, and fishing and boating opportunities. The Riverwalk, portions of which have been built since publication of the *Washington Specific Plan*, will provide a continuous pedestrian and bicycle linkage from Lighthouse Marina development at the north to the barge canal at the south. This trail will be 12 feet wide and paved and incorporate benches, bike rack, tree plantings, multi-purpose event spaces, and thematic pedestrian lighting. For specific design guidelines, the *Washington Specific Plan* incorporates the SRMP by reference.

West Sacramento Bicycle and Pedestrian Path Master Plan

The *West Sacramento Bicycle and Pedestrian Path Master Plan* (Callander Associates 1991) and *Addendum* (City of West Sacramento Parks and Community Services Department 1995) propose future recreation trails, bike paths, lanes, and routes along the majority of the study area. The plan identifies the following relevant objectives and policies:

Objective 2 Use of City Infrastructure: Utilize city infrastructure including streets, street and railroad rights-of-way, and utility and drainage easements for development of bicycle and pedestrian path system.

Policy 2.7: Utilize non-vehicular areas, wherever possible, for locating bicycle and pedestrian facilities away from motor vehicles, to enhance safety and enjoyment and minimize distances between destination points. Utilize Reclamation District rights-of-way and maintenance roads for paths wherever feasible, and negotiate easements for paths as needed.

Objective 3 Recreational Opportunities: Facilitate city-wide and regional recreation opportunities for bicycling, hiking and jogging.

Policy 3.1: Link city parks, schools, riverfront, open space areas, and scenic areas to the system of bicycle and pedestrian paths.

Policy 3.2: Provide a system of continuous bicycle and pedestrian pathways along the Sacramento River and other waterways, where feasible.

Yolo Bypass Wildlife Area Land Management Plan

The *Yolo Bypass Wildlife Area Land Management Plan* (prepared jointly by DFG and the Yolo Basin Foundation) guides the management of habitats, species, appropriate public uses, and programs within the Yolo Bypass Wildlife Area. Specific to recreation, it identifies and guides appropriate, compatible public use opportunities.

Authorized Public Use Element

Goal PU-1: Increase existing and provide new long-term opportunities for appropriate wildlife-dependent activities by the public.

Task 9: Build access points for anglers with limited mobility along East Toe Drain.

Goal PU-3: Coordinate public access to and use of facilities including tour routes, parking areas, Putah Creek, the planned Pacific Flyway Center, and other areas to accommodate a variety of different user groups.

Task 35: Cooperate with the City of West Sacramento in assessing feasibility of access from the east side.

Task 36: Cooperate with agencies promoting regional hiking, bicycle, and equestrian trail connections including Caltrans, Delta Protection Commission, Yolo County, City of Davis, and City of West Sacramento.

Goal PU-8: Facilitate safe use of the Yolo Bypass Wildlife Area by informing the public of potential risks, and also develop an emergency response plan.

Task 5: Restrict access to unsafe areas such as construction zones and at times, active farming areas.

Yolo County General Plan

The *Yolo County General Plan* (Yolo County Community Development Agency 1983) identifies the following goals, objectives, and policies for the implementation plan.

Circulation

Policy CIR-13: Bicycle Routes and Facilities. Yolo County shall promote and ensure opportunities for bicycle use. The following means shall be used to achieve this policy: Encouragement and establishment of bike routes along trails, on levees, along railroad levees, along drainage canals, and along transmission right-of-ways where feasible.

Recreation

Policy REC-7: Urban Waterfront Land Use. Yolo County shall require that a portion of urban waterfront, other than the Port of West Sacramento and existing industrial uses, should be used for water-dependent activities including, but not limited to, recreation, tourism, scenic public walkways, waterview restaurants, marinas, fishing access, small waterfront parks, and interpretation projects with retained and enhanced riparian vegetation and may include related residential development in a proportion established by conditional use permit but not to exceed one-half of the total land area of the project.

Urban waterfront overlay zoning shall be established to locate and define the extent of such areas and shall insure access to the river for all residents.

Open Space and Recreation Element

The revised Yolo County Open Space and Recreation Element (Yolo County Parks and Natural Resources 2002) identifies the following goals, objectives, and policies for the implementation plan:

Objective RO-2: Establishment of a variety of outdoor recreational and educational opportunities along Lower Cache Creek, the Sacramento River, Lower Putah Creek, and within the Yolo Bypass for use by the public.

Policy RP-8: The County shall encourage and support the development of private recreation facilities that preserve scenic and environmentally sensitive resources and that do not result in the creation of land use conflicts.

Policy RP-10: The County shall work with willing landowners to create a continuous corridor of natural open space along Lower Cache Creek, Lower Putah Creek, the Sacramento River and within the Yolo Bypass with provision for limited access at specific locations to recreational and educational uses from a County road or highway. The County shall also consider establishing bicycle access to select areas.

Policy RP-12: Recreational uses shall be clustered at locations along Cache Creek, Lower Putah Creek, and the Sacramento River, in order to minimize habitat disturbance and provide efficient and cost-effective management by the County. All access, whether by road or by trail, shall be through an entry point which can be controlled.

Policy RP-17: The County shall support improved access for bank fishing where safe and adequate parking can be provided and with acquisition of proper rights-of-access from the landowner. Adequate policing, garbage cleanup, sanitation facilities, and fire suppression for such access shall be provided.

Yolo County Oak Woodland Conservation and Enhancement Plan

Many recreationists use the oak woodlands in Yolo County for hiking, bicycling, equestrian, hunting, and other recreation opportunities. The *Yolo County Oak Woodland Conservation and Enhancement Plan* promotes voluntary efforts to conserve and enhance the county's existing oak woodlands, which provide significant aesthetic, ecological, and economic benefits (Yolo County Planning, Resources, and Public Works Department 2007)

3.15.2.2 Environmental Setting

For many years, the levee system around the city of West Sacramento has provided a popular open space venue for informal recreation activities. The views afforded by the levees' elevated height and proximity to the natural areas along the Sacramento River, Sacramento Bypass, Yolo Bypass, and the Sacramento DWSC entice many types of recreationists. Residents use the levees for walking, running, biking, fishing, visiting the waterfront, and for wildlife viewing. In addition to the widespread informal use of the levees themselves, the City of West Sacramento and some private entities operate some formal recreation facilities in the WSLIP study area. More detailed descriptions of the facilities and recreation activities taking place along each levee reach follow below.

Boating is a significant recreational use on the waterways surrounding the city. The Sacramento River is a popular regional waterway for motorized boat use, especially within the urbanized reach of the river flowing by the cities of Sacramento and West Sacramento. The riparian vegetation and mature trees lining much of the river in this stretch, combined with the on-river dining opportunities in the Natomas and Old Town Sacramento areas, provide an attractive boating corridor. West Sacramento is also home to two marinas on the Sacramento River: the Sacramento

Yacht Club and the Sherwood Harbor Marina. The City also operates the Broderick Boat Launching, Park, providing boat ramps and other park amenities.

The calm waters of the DWSC are also a popular boating destination. The River City Rowing Club and the University of California, Davis, crew teams use the DWSC for practice and competition, and other non-motorized boats regularly ply the channel carrying anglers and wildlife viewers. The Lake Washington Sailing Club and the Lake Washington Outboard Club also call the DWSC their home.

Several recreation facilities and opportunities along the left bank of the Sacramento River (on the Sacramento side) are significantly enhanced by views of the mature riparian vegetation along the Sacramento River North and South Levees in West Sacramento. Some of the major facilities and recreation opportunities are Discovery Park, Miller Park, River View Marina, River Bank Marina, Sacramento Marina, Virgin Sturgeon Restaurant and Marina, Le Rivage hotel and marina, and informal recreational use of the levees in the Pocket and Little Pocket areas of Sacramento.

3.15.2.2.1 Sacramento River North Levee

The Sacramento River North Levee sees a variety of recreational uses, both informal and formal. From the I-80 crossing south to the Broderick Boat Ramp, there is a fairly wide vegetated berm between the levee and the river, and this berm attracts many visitors for fishing, walking, running, biking, and visiting the waterfront. Although access in this area technically is considered trespassing, the City's Police Department and Reclamation District 811 generally do not prosecute for informal recreational use (Shpak pers. comm. 2009). There is very little recreational use of the levee north of the I-80 crossing, as access is restricted by private property and the City's water treatment plant. Additionally, very little recreational use occurs on or near the levee south of the Pioneer Bridge because of the presence of industrial facilities and a steep river bank. While the undeveloped riverfront between the Tower and Pioneer Bridges experiences some recreational visitation, the main recreational use of this area is parking for River Cats games and other events at Raley Field.

Formal recreation facilities along the Sacramento River North Levee are listed below.

- **Bryte Park**. Bryte Park is a City of West Sacramento community park, the northern edge of which abuts the landside toe of the Sacramento River North Levee just west of the Riverbank Elementary School. Numerous amenities are available to the West Sacramento community at Bryte Park, including four softball diamonds (two of which are lighted) one hardball diamond, eight soccer fields, full court basketball, football facilities, walking paths, a track, a picnic area with barbecues, a tot lot, a fitness course, restrooms, and the Club West Teen Center, home to an afterschool teen program.
- **Broderick Boat Ramp**. This double-ramp boat launch and picnic facility is operated by the City of West Sacramento and is located on the waterside of the Sacramento River North Levee, just downstream from the Sacramento River's confluence with the American River. It is a popular regional destination because it is the only free, vehicle-accessible public boat ramp in the Sacramento metropolitan area. The City completed improvements to the launch capacity of the ramp and expanded the picnic and restroom facilities during summer 2009 (Shpak pers. comm. 2009).
- **River Walk Park**. River Walk Park, a City of West Sacramento community park, is the City's main event venue on the river. The City frequently holds special events at this park during the summer months (Shpak pers. comm. 2009). River Walk Park features a paved pedestrian

promenade along the length of the park (from I Street Bridge south to the Tower Bridge) studded with educational signs discussing the settlement of Sacramento and the river's natural habitat, as well as barbecues, picnic areas, and large expanses of turf with a view of Old Town Sacramento across the river. The City has secured funding to extend the promenade 250 feet to the south of the Tower Bridge if the project is built by summer 2011.

3.15.2.2.2 Sacramento River South Levee

For most of its length, the waterside of the Sacramento River South Levee is fairly steep but supports a mature riparian forest that is attractive to many recreationists. South River Road, a two-way paved road, tops the Sacramento River South Levee for most of its extent through the study area. Although South River Road is considered a rural route and features very narrow shoulders with no designated bike lane, it remains a popular bicycling corridor in the region. South River Road also provides easy access for fishing along the Sacramento River, making fishing a very widespread informal recreation activity along the Sacramento River South Levee. On a smaller scale, pedestrians and equestrians also use South River Road.

Located landward of the Sacramento River South Levee, toward its northern end, is an area locally known as the Honda Hills. The area was formerly a USACE dredge spoils site, and spoils placement has left a rolling, uneven terrain that has since been colonized by trees and vegetation. The site is now owned by the City of West Sacramento and is informally used by riders of off-highway vehicles, equestrians, and pedestrians.

Bees Lakes, a heavily wooded natural area surrounding two fairly large ponds, sits just west of the Sacramento River South Levee approximately 2 miles south of the barge canal along South River Road. Because of the thick vegetation, access is difficult, but it is a popular area for nature viewers and paintball enthusiasts (Shpak pers. comm. 2009).

Formal recreation facilities along this levee stretch are listed below.

- **Delta Gardens Park**. Delta Gardens Park is a City of West Sacramento neighborhood park located approximately 0.5 mile south of the barge canal. The easternmost extent of the park is about 150 feet from the landside toe of the Sacramento River South Levee. Park amenities include youth and tot play structures, picnic areas, barbecues, half-court basketball, a climbing boulder, a performance patio and a turf play area (City of West Sacramento Department of Parks and Recreation 2009b).
- **Sacramento Yacht Club**. The Sacramento River Yacht Club is a non-profit, member-owned private club located on the waterside of the Sacramento River South Levee approximately 2 miles south of the barge canal. Facilities at the Yacht Club include a clubhouse, bar, galley, marina, and covered slips. The public (non-members) can rent facilities on days when it is not in private use.
- **Sherwood Harbor Marina and RV Park.** The Sherwood Harbor Marina and RV Park is a privately owned public marina and RV park with 130 boat slips and 44 RV sites. It is located approximately 0.5 mile south of the Sacramento Yacht Club on the waterside of the Sacramento River South Levee and is the only riverfront RV park in the Sacramento metropolitan area. Recreation opportunities at the Marina include camping, boating (motor boating, kayaking, and canoeing), picnicking, fishing, swimming, wildlife viewing, and walking. Facilities include restrooms, a pump-out station, fueling station, convenience store, bait shop, and laundry facilities (Sacramento River Recreational and Public Access Guide 2009).

3.15.2.2.3 Port North Levee

Recreational use along the Port North Levee is very limited because most of the land is owned by industrial enterprises (including the Port of West Sacramento) and access is restricted. Some trespassers access the barge canal at the eastern end of the Port North Levee through holes in the fencing at the terminus of South River Road, using the area for fishing and visiting the waterfront. A similar situation exists at the opposite end of the Port North Levee, with visitors accessing the dead-end streets at the western edge of the city and traveling south along the Yolo Bypass Levee to fish and visit the waterfront on the western end of the Port North Levee. Some fishing also occurs off of the Jefferson Boulevard bridges and the riverbanks immediately adjacent to Jefferson Boulevard (Shpak pers. comm. 2009).

Formal recreation facilities along this levee stretch are listed below.

- **River City Rowing Club and UC Davis Crew**. The River City Rowing Club and the University of California, Davis, crew teams operate out of the Port of West Sacramento, using the Port's calm waters to practice and compete. Both groups' facilities are located on the waterside of the Port North Levee, along the edge of the turning basin.
- **Lake Washington Sailing and Outboard Clubs**. These private groups provide membership-only access to the Port of Sacramento. Their facility is located next to the River City Rowing Club, at the edge of the turning basin.
- **Sam Combs Park**. Sam Combs Park is a City of West Sacramento neighborhood park located just to the north of the Port North Levee near Jefferson Boulevard. Park facilities include barbecues, horseshoe pits, a tot lot, walking paths, restrooms, and a fenced off-leash dog play area.

3.15.2.2.4 Port South Levee

Most of the recreational use along the Port South Levee is informal, except for hand-portaged boating, fishing, walking, and biking at the Barge Canal Recreational Access, which is described below. The western third of the Port South Levee runs through industrial properties, and the middle third of the levee is on property owned by the Port of West Sacramento. Any recreational use of the levee in those areas technically is considered trespassing, but informal recreational uses occur there nonetheless; these uses are mainly fishing, picnicking, walking, running, and biking.

The Honda Hills area, described above, is located just south of the eastern end of the Port South Levee. As previously mentioned, the site is owned by the City of West Sacramento and is informally used by riders of off-highway vehicles, equestrians, and pedestrians. The eastern end of the Port South Levee itself is informally used for fishing and waterfront visitation (Shpak pers. comm. 2009).

One formal recreation facility is located along this levee stretch.

- **Barge Canal Recreational Access**. The Barge Canal Recreational Access provides a formal access point for the Port South Levee at the western end of the Jefferson Boulevard/South River Road intersection. Facilities at the site include a hand-carry boat ramp, an approximately 0.25-mile-long walking/biking trail along the Port South Levee, picnic tables, benches, interpretive panels about environmental resources and the Port of West Sacramento, and off-street vehicle parking.

3.15.2.2.5 South Cross Levee

There is very little recreational use of the South Cross Levee, as the levee extends through private property. Several of the landowners have erected fences across the levee, preventing public access.

3.15.2.2.6 DWSC East Levee

The DWSC East Levee is closed to vehicular access north of the pump station. No formal recreation facilities exist on the levee; however, the levee and its wide waterside berm are an attractive location for a number of informal recreation activities. Frequent recreational uses of the levee and waterside berm include walking, running, wildlife viewing, picnicking, biking, and fishing. The levee and berm in this area are on private property, so public use technically is considered trespassing, although the City of West Sacramento Police Department and Reclamation District 900 do not prosecute for non-motorized use (Shpak pers. comm. 2009).

3.15.2.2.7 DWSC West Levee and Yolo Bypass Levee

Along the west side of the Yolo Bypass Levee and the upper portion of the DWSC West Levee lies the Yolo Bypass Wildlife Area, which comprises approximately 16,770 acres of managed wildlife habitat and agricultural land within the Yolo Bypass. The Yolo Bypass Wildlife Area is unique in the way agriculture, wildlife habitat, and flood protection objectives are achieved in a manner compatible with providing ample opportunities for public access, recreation, and natural resource education. Recreation activities in the Wildlife Area include environmental education and interpretation programs, hunting, fishing, wildlife viewing, nature photography, hiking, and the collection of native plant materials for cultural use by Native Americans.

Recreation activities that occur adjacent to the Yolo Bypass Levee and the DWSC West Levee are primarily hunting, fishing, and wildlife viewing. Waterfowl and pheasant are the most popular game species hunted at the Wildlife Area, but visitors also hunt other upland game species, including dove. The hunting season at the Wildlife Area traditionally runs from early September through the end of January each year, although the hunting season often is interrupted by seasonal flooding of the Yolo Bypass. The East Toe Drain, which abuts the Yolo Bypass Levee and DWSC West Levee, is a popular fishing spot in the Wildlife Area. Game species fished in the East Toe Drain include sturgeon, catfish, black bass, and striped bass. During the non-hunting season, several walking trails are open for wildlife viewing near the DWSC West Levee. A rich array of wildlife uses the Wildlife Area, including more than 200 known species of birds, many mammal species, and large numbers of fish, amphibians, and invertebrates (California Department of Fish and Game and Yolo Basin Foundation 2008).

A minor amount of recreational use of the Yolo Bypass and DWSC West Levees occurs from the West Sacramento side. Access is gained from the streets that dead-end into the Yolo Bypass Levee in West Sacramento south of I-80, and visitors travel south along the Yolo Bypass Levee to the DWSC West Levee. Use is generally limited to fishing in the DWSC and east toe drain and visiting the waterfront.

Formal recreation facilities along this levee stretch are listed below.

- **Yolo Causeway Bicycle Path**. The Yolo Causeway Bicycle Path crosses over the Yolo Bypass Levee just north of I-80, connecting with the I-80 infrastructure just west of the levee. This bicycle path is a part of a larger bicycle corridor that connects Davis with Sacramento. The corridor is extremely popular with both recreational bicyclists and commuters.

- **Roland Hensley Bike Park**. The Roland Hensley Bike Park is a City of West Sacramento Mini Park and bicycle staging area that also connects the Yolo Causeway Bicycle Path to West Capitol Avenue. It provides two connection routes: directly from the park to West Capitol Avenue, and via a class one bicycle lane that runs along the Yolo Bypass Levee's toe for approximately 1,200 feet, joining up with West Capitol Avenue farther east. The park itself features a turf picnic area and drinking fountains.

3.15.2.2.8 Sacramento Bypass Levee

Very little known recreational use occurs in the vicinity of the Sacramento Bypass Levee. Occasional visitors park in the gravel area just south of the Sacramento Weir and west of Old River Road and walk into the Sacramento Bypass to fish (Shpak pers. comm. 2009). There are no formal recreation facilities on the Sacramento Bypass Levee.

3.15.3 Environmental Consequences

This section describes recreation effects associated with the program. It describes the methods used to determine the effects of the program and lists the thresholds used to conclude whether an effect would be significant. Measures to mitigate (i.e., avoid, minimize, rectify, reduce, eliminate, or compensate for) significant effects accompany each discussion.

3.15.3.1 Assessment Methods

Potential effects on recreation related to construction or operation are considered at a program level. Effects on recreation related to implementation of the program were evaluated qualitatively. Generally, construction activities could result in a short-term loss of recreation opportunities by disrupting use of recreation areas or recreational boating corridors. A long-term effect could occur if a recreation opportunity is eliminated or the quality of that opportunity is severely reduced as a result of permanent program-related structures or operations. Long-term beneficial effects could occur if new or enhanced recreation opportunities are created through implementation of the program.

3.15.3.2 Determination of Effects

For this analysis, an effect pertaining to recreation was considered significant if it would result in any of the following environmental effects, which are based on professional practice and State CEQA Guidelines Appendix G (14 CCR 15000 *et seq*.):

- increase the use of existing neighborhood and regional parks or other recreation facilities such that substantial physical deterioration of the facility would occur or be accelerated;
- include recreation facilities or require the construction or expansion of recreation facilities that might have a significant physical effect on the environment;
- substantially restrict or reduce the availability or quality of existing recreation opportunities in the project vicinity; or
- implement operational or construction-related activities related to the placement of project facilities that would cause a substantial long-term disruption of any institutionally recognized

recreation activities. Institutionally recognized recreation activities are those associated with an established publicly or privately operated recreation facility, or those actively administered or promoted by a public or private entity.

3.15.3.3 Effects and Mitigation Measures

3.15.3.3.1 No Action Alternative

To summarize Chapter 2, Alternatives, the No Action Alternative is the continuation of the existing deficiencies along the nine levee reaches and absence of levee alternatives to increase the level of protection resulting in continued or even potentially increased risk of catastrophic flooding of the city. Current levee operations and maintenance activities would continue. No potential construction-related effects on recreation facilities would occur.

Existing recreation opportunities in the study area are expected to remain unchanged under the No Action Alternative. Recreational use of the levees, riverbank, parks, and other facilities would continue as established. The City does not plan to move forward with development of any recreational elements on or near the city's levees without prior implementation of necessary levee upgrades (Shpak Pers. Comm. 2009). Development of new recreational opportunities on or adjacent to levees identified in the City's planning documents would therefore not occur under the No Action Alternative. However, no substantial increase in use of existing recreation facilities should occur under the No Action Alternative, since further development (and further population growth) in West Sacramento could be halted under the No Action Alternative if the city's flood hazard designation is changed, as described in Chapter 2, Alternatives.

Without levee improvements, the risk of levee failure would continue and could even increase, as described in Chapter 2, Alternatives. A catastrophic levee failure would result in flooding and inundation that could significantly damage existing facilities and infrastructure, and erode soil, uproot plants, and otherwise damage substrate by hydraulic force. This would render recreation facilities, informal recreation areas, and trails unusable until cleanup and restoration activities could be undertaken. It is possible that after a catastrophic flood event, recreation facilities may never be fully restored to their former condition, permanently reducing the quality and/or quantity of recreation opportunities in the area. In addition, scenic vistas for existing and future recreation facilities could be damaged irreparably or for an extended period of time which would reduce the enjoyment derived by recreationists. Given the uncertainty of the occurrence or magnitude of such an event, potential effects on recreation cannot be quantified based on available information.

In its levee vegetation guidance, USACE has established a woody vegetation-free zone required for operations and maintenance of Federal project levees. Woody vegetation has been allowed to persist within the study area and more broadly throughout the SRFCP in part to account for the functions and values attributed to riparian vegetation. However, in light of recent levee failures and flooding disasters in the United States (e.g., the flooding related to Hurricanes Katrina and Rita), compliance with the vegetation-free zone will be more strictly adhered to and enforced.

Compliance with the levee vegetation guidance could result in the removal of a substantial amount of vegetation, including vegetation that comprises riparian habitat and supports fish and wildlife populations. Many recreation activities rely on or are significantly enhanced by the presence of mature woody vegetation. Anglers rely on trees to provide shade during fishing activities, and wildlife viewers are attracted to areas with mature woody vegetation because of the wealth of

wildlife such vegetation supports. Many other users, including pedestrians, bicyclists, equestrians, and boaters also rely on this woody vegetation for shade, and for the visual character it contributes to the landscape. Removal of a substantial amount of this riparian vegetation in compliance with the levee vegetation guidance would significantly affect recreation in the program study area, similar to Effect REC-3 described below.

For areas where a setback levee is proposed under the WSLIP, which may allow existing vegetation to be preserved, or where the vegetation is found to be in compliance with USACE levee vegetation guidance, the No Action Alternative and flood and recreation program alternatives could result in effects on riparian vegetation that are comparatively similar. However, absent a site-specific study of the application of the USACE levee vegetation guidance, calculation of the magnitude and significance of effects are too speculative based on available information.

3.15.3.3.2 Flood and Recreation Program Alternatives

Effect REC-1: Temporary Disruption of Recreation Opportunities during Construction

Construction activities associated with implementation of the program have the potential to temporarily disrupt recreation activities occurring in the local area. This effect is discussed as it relates to each reach in the Affected Reaches section below.

Program Alternatives Associated with This Effect

Implementation of all alternatives could cause Effect REC-1.

Program	Alternative	
Flood	▪ Flood wall ▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Closure structure ▪ Interior drain ▪ Jet grouting ▪ Relief wells ▪ Seepage berm	▪ Sheet pile wall ▪ Slurry cutoff wall ▪ Slope flattening ▪ Stability berm ▪ Rock slope protection ▪ DWSC closure structure ▪ Setback levee ▪ Vegetation removal
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

Construction activities could temporarily affect recreation in all of the program reaches, except for the South Cross Levee, as there is currently no recreational use of the area.

Sacramento River North Levee

In addition to the formal recreation facilities located along the Sacramento River North Levee (Bryte Park, the Broderick Boat Ramp, and River Walk Park), many informal recreation activities occur along the levee and waterside berm, including fishing, walking, biking, running, and visiting the

waterfront. Temporary disruption of these activities would occur during construction activities when the levee crown and adjacent construction and staging areas are closed to public access. Even if the recreation areas themselves are not closed, proximity to construction equipment and activities may degrade recreational experiences. However, this effect is temporary and there are alternative locations for these types of recreation activities in the city. With implementation of the environmental commitment requiring notification of construction area closure (described in Section 2.9, Chapter 2, Alternatives) to ensure public safety and provide closure notice in advance of construction activities, this temporary effect would be less than significant. No mitigation is required. A discussion of temporary obstruction of access to local marina or boat launch facilities is located under Effect REC-2, below.

Effect REC-1 Finding—Sacramento River North Levee	With Mitigation
Less than significant	N/A

Sacramento River South Levee

In addition to the formal recreation facility (Delta Gardens Park) located along the landside of the Sacramento River South Levee, many informal recreational activities occur along the waterside of the levee. Fishing from the riverbank and biking along South River Road are very popular activities in this stretch, and the levee also plays host to pedestrians, equestrians, and visitors to the waterfront. The area west of the landside toe at the northern end of the Sacramento River South Levee is a popular spot for off-highway vehicle use, as well as equestrian and pedestrian use. Paintball enthusiasts utilize the thickly forested area around Bees Lakes, which sit at the landside toe of the levee 2 miles south of the barge canal.

Temporary disruption of these activities would occur during construction activities when the levee crown and adjacent construction and staging areas are closed to public access. Even if the recreation areas themselves are not closed, proximity to construction equipment and activities may degrade recreational experiences. However, this effect would be temporary and there are alternative locations for these types of recreation activities within the city. With implementation of the environmental commitment requiring notification of construction area closure (described in Section 2.9, Chapter 2, Alternatives) to ensure public safety and provide closure notice in advance of construction activities, this effect would be less than significant. No mitigation is required.

Effect REC-1 Finding—Sacramento River South Levee	With Mitigation
Less than significant	N/A

Port North Levee

In addition to the formal recreation facility (Sam Combs Park) located along the landside of the Port North Levee, UC Davis and the River City Rowing Club operate rowing facilities and the Lake Washington Sailing and Outboard Clubs operate private water access areas out of the Port of West Sacramento. Other recreational use on or near the Port North Levee is very limited, because most of the land is owned by industrial enterprises and access is restricted.

Temporary disruption of these activities could occur during construction activities when the levee crown and adjacent construction and staging areas are closed to public access. Recreational boating on the barge canal and activities that take place in Sam Combs Park may be indirectly affected by

proximity to construction equipment and construction activities that could degrade recreational experiences.

However, this effect would be temporary. With implementation of the environmental commitment requiring notification of construction area closure to ensure public safety and provide closure notice in advance of construction activities, and the environmental commitment to coordinate construction periods with the port of west Sacramento to ensure access to the Port (where the UC Davis and River City Rowing Club facilities and Lake Washington Sailing and Outboard Clubs are located) remains open during construction(both described in Section 2.9, Chapter 2, Alternatives) , this effect would be less than significant. No mitigation is required.

Effect REC-1 Finding—Port North Levee	With Mitigation
Less than significant	N/A

Port South Levee

Much of the recreation activity along the Port South Levee occurs at the Barge Canal Recreational Access. Anglers and recreational boaters use the boat launch facility to hand-launch their vessels and a significant number of anglers cast their lines from under the mature oak trees on the bank. Effects of construction activities on the boat launch facility are explored below under Effect REC-2. Some recreation activity occurs along the western two-thirds of the Port South Levee (mostly fishing, picnicking, walking, running, and biking), but these uses are technically considered trespassing since the property is in private or Port ownership. Fishing and waterfront visitation occur along the levee east of Jefferson Boulevard, and the area south of the levee's eastern end is used by pedestrians and riders of off-road vehicles and horses.

Temporary disruption of these activities would occur during construction activities when the levee crown and adjacent construction and staging areas are closed to public access. Even if the recreation areas themselves are not closed, proximity to construction equipment and activities may degrade recreational experiences. However, this effect is temporary and there are alternative locations for these types of recreation activities within the city. With implementation of the environmental commitment requiring notification of construction area closure to ensure public safety and provide closure notice in advance of construction activities (described in Section 2.9, Chapter 2, Alternatives) to ensure public safety and provide closure notice in advance of construction activities, this effect would be less than significant. No mitigation is required.

Effect REC-1 Finding—Port South Levee	With Mitigation
Less than significant	N/A

DWSC West Levee

Very little recreation activity occurs on the DWSC West Levee because it s relatively inaccessible to the public. As described above, visitors must travel through the industrial portion of West Sacramento and down the Yolo Bypass Levee to access the DWSC West Levee. However, a number of recreation activities occur within sight of the DWSC Levee in the adjacent Yolo Bypass Wildlife Area. These activities include hunting, wildlife-viewing, and fishing in the east toe drain, which is located along the landside toe of the DWSC Levee.

Temporary disruption of recreation opportunities on the levee itself would occur during construction activities when the levee crown and adjacent construction and staging areas are closed to public access. Recreation activities in the Yolo Bypass Wildlife Area may be affected by proximity to construction equipment and noises that could degrade recreational experiences.

However, this construction-related effect would be temporary and there are alternative locations for these types of recreation activities within the Yolo Bypass Wildlife Area. With implementation of the environmental commitment requiring notification of construction area closure to ensure public safety and provide closure notice in advance of construction activities (described in Section 2.9, Chapter 2, Alternatives) to ensure public safety and provide closure notice in advance of construction activities, this effect would be less than significant. No mitigation is required.

Effect REC-1 Finding—DWSC West Levee	With Mitigation
Less than significant	N/A

DWSC East Levee

Although there are no formal recreation facilities located along the DWSC East Levee, many informal recreation activities occur along the levee and waterside berm, including walking, running, wildlife viewing, picnicking, biking, and fishing. Temporary disruption of these activities would occur during construction when the levee crown and adjacent construction and staging areas are closed to public access. Even if the recreation areas themselves are not closed, proximity to construction equipment and activities may degrade recreational experiences. However, this effect is temporary and there are alternative locations for these types of recreation activities within the City. With implementation of the environmental commitment requiring notification of construction area closure to ensure public safety and provide closure notice in advance of construction activities (described in Section 2.9, Chapter 2, Alternatives) to ensure public safety and provide closure notice in advance of construction activities, this effect would be less than significant. No mitigation is required.

Effect REC-1 Finding—DWSC East Levee	With Mitigation
Less than significant	N/A

Yolo Bypass Levee

Informal recreational use of the Yolo Bypass Levee is very limited—the levee is mainly used as an access route to the DWSC West levee. However, the Yolo Causeway Bicycle Path, which crosses the Yolo Bypass Levee just north of I-80, is part of an extremely popular regional bicycle corridor connecting Davis with Sacramento. The Roland Hensley Bike Park, located at the toe of the levee, serves as a staging area and connects the Yolo Causeway Bicycle Path to West Capitol Avenue.

Temporary disruption of the bicycle corridor and any informal uses may occur during construction activities. Because informal use of the area is very limited, and WSAFCA will implement the environmental commitment requiring notification of construction area closure (described in Chapter 2, Alternatives) to ensure public safety and provide closure notice in advance of construction activities, temporary disruption of informal uses is considered less than significant.

However, if construction activities require the closure of the Yolo Causeway Bicycle Path or the trail connecting it with West Capitol Avenue, a significant number of recreational bicyclists and

commuters would be significantly affected. There are no alternative bicycle routes crossing the Yolo Bypass. This effect is considered significant, but would be reduced to a level of less than significant with implementation of Mitigation Measure REC-MM-1, described below.

Effect REC-1 Finding—Yolo Bypass Levee	With Mitigation
Significant	Less than significant

Mitigation

Mitigation Measure REC-MM-1: Temporarily Re-Route Yolo Causeway Bicycle Path

If closure of the Yolo Causeway Bicycle Path or the trail connecting it with West Capitol Avenue is necessary, WSAFCA will provide a safe alternative route. This alternative route will be well marked and will provide bicyclists with a way to access the bicycle lanes on the I-80 infrastructure, ensuring that a bicycle connection between Davis and Sacramento remains uninterrupted.

Sacramento Bypass Levee

No formal recreation facilities are located along the Sacramento Bypass Levee, although occasional visitors use the levee to access the bypass itself for fishing or wildlife viewing. Temporary disruption of access along the Sacramento Bypass Levee would occur during construction activities when the levee crown and adjacent construction and staging areas are closed. Even if the recreation areas themselves are not closed, proximity to construction equipment and activities may degrade recreational experiences. However, this effect is temporary and there are alternative locations for fishing within the city. With implementation of the environmental commitment requiring notification of construction area closure to ensure public safety and provide closure notice in advance of construction activities (described in Section 2.9, Chapter 2, Alternatives) to ensure public safety and provide closure notice in advance of construction activities, this effect would be less than significant. No mitigation is required.

Effect REC-1 Finding—Sacramento Bypass Levee	With Mitigation
Less than significant	N/A

Effect REC-2: Temporary Obstruction of Access to Marina or Boat Launch Facilities

Construction activities along the Sacramento River North, Sacramento River South, and Port South levees could temporarily obstruct access to local marina or boat launch facilities. This effect is discussed as it relates to each reach.

Program Alternatives Associated with This Effect

Implementation of alternatives that may require road closures or closure of the levee crown in the vicinity of marinas or boat launch facilities could cause Effect REC-2. These alternatives are as follows:

Program	Alternative	
Flood	▪ Flood wall ▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Closure structure ▪ Interior drain ▪ Jet grouting ▪ Relief wells	▪ Seepage berm ▪ Sheet pile wall ▪ Slurry cutoff wall ▪ Slope flattening ▪ Stability berm ▪ Rock slope protection ▪ DWSC closure structure ▪ Setback levee
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

Sacramento River North Levee

The Broderick Boat Ramp, located on the waterside of the Sacramento River North Levee, is West Sacramento's only vehicle-accessible boat ramp, and provides the Sacramento region's only free, vehicle-accessible boat launch facility. The agreement for grant funding acquired by the City to upgrade the boat ramp facilities stipulates that the City must obtain prior approval of the Department of Boating and Waterways before closing the facility to any recreational vehicle.

Visitors must use the levee-top road (Levee Road) to access the boat ramp, but temporary closure of Levee Road may be necessary during program construction activities. Alternatives proposed in the Sacramento River North Levee reach that may require road closure are adjacent levee raise, full levee raise, in-place levee raise, rock slope protection, sheet pile wall, slope flattening, slurry cutoff wall, closure, jet grouting, and recreation elements. Closure of the region's only free boat launch facility would conflict with the City's Department of Boating and Waterways grant agreement and reduce access to recreational boating opportunities in the project vicinity. However, with implementation of the environmental commitments to preserve marina and boat launch access and to obtain approval for Broderick Boat Ramp closure (described in Section 2.9, Chapter 2, Alternatives), this effect would be less than significant. No mitigation is required.

Effect REC-2 Finding—Sacramento River North Levee	With Mitigation
Less than significant	N/A

Sacramento River South Levee

The Sacramento Yacht Club and the Sherwood Harbor Marina and RV Park are both located on the waterside of the Sacramento River South Levee. These are the only two marinas located in West Sacramento. Both offer a large number of boat slips, and Sherwood Harbor is the only riverfront RV park in the Sacramento metropolitan area. Visitors must use the levee-top road (South River Road)

to access the marinas, but temporary closure of the levee road may be necessary during program construction activities. Alternatives proposed in the Sacramento River South Levee reach that may require road closure are adjacent levee raise, full levee raise, in-place levee raise, relief wells, rock slope protection, setback levee, slope flattening, slurry cutoff wall, stability berm, and recreation elements. Closure of the City's only marinas would substantially reduce the availability of existing recreational boating opportunities in the project vicinity. However, with implementation of the environmental commitment to preserve marina and boat launch access (described in Section 2.9, Chapter 2, Alternatives), this effect would be less than significant. No mitigation is required.

Effect REC-2 Finding—Sacramento River South Levee	With Mitigation
Less than significant	N/A

Port South Levee

The Barge Canal Recreational Access provides a free, non-motorized boat ramp that is used on a daily basis by anglers and other boaters to launch their craft and access the waters of the barge canal and DWSC. The ramp itself slopes toward the water along the waterside of the Port South Levee, and boaters must carry their boats across the levee to access the ramp. Construction activities and the presence of construction equipment may block access to the ramp during program construction activities. Alternatives proposed in the Port South Levee reach that may block access to the ramp are flood wall, adjacent levee raise, full levee raise, in-place levee raise, slope flattening, slurry cutoff wall, closure, and recreation elements.

Because the boat ramp at the Barge Canal Recreational Access is the only public boat access to the barge canal or DWSC, temporary closure of this facility would block public boating access to these waters. However, with implementation of the environmental commitment to preserve marina and boat launch access (described in Section 2.9, Chapter 2, and Alternatives), this effect would be less than significant. No mitigation is required.

Effect REC-2 Finding—Port South Levee	With Mitigation
Less than significant	N/A

Effect REC-3: Long-Term Reduction in Quality of Existing Recreation Opportunities in the Levee Corridor

All flood program alternatives would follow USACE's policies regarding vegetation on levees. This would require removal of a substantial amount of mature trees and vegetation from the banks of many of the levees in the study area, as the new policy forbids woody vegetation on the slopes and crown of the levee or within 15 feet of the waterside and landside levee toes. These zones would be maintained free of woody vegetation in perpetuity.

Many recreation activities rely on or are significantly enhanced by the presence of mature woody vegetation. Anglers rely on trees to provide shade during fishing activities, and wildlife viewers are attracted to areas with mature woody vegetation because of the wealth of wildlife such vegetation supports. Many other users, including pedestrians, bicyclists, equestrians and boaters also rely on this woody vegetation for shade, and for the visual character it contributes to the landscape (visual effects of permanent vegetation removal are discussed in Section3.14, Visual Resources).

The effect on recreation caused by compliance with USACE vegetation policy is discussed as it relates to each reach in the Affected Reaches section below.

Program Alternatives Associated with This Effect

Implementation of any of the flood program alternatives could cause Effect REC-3.

Program	Alternative	
Flood	▪ Flood wall ▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Closure structure ▪ Interior drain ▪ Jet grouting ▪ Relief wells ▪ Seepage berm	▪ Sheet pile wall ▪ Slurry cutoff wall ▪ Slope flattening ▪ Stability berm ▪ Rock slope protection ▪ DWSC closure structure ▪ Setback levee ▪ Vegetation removal

Affected Reaches

Compliance with USACE vegetation policy would affect recreation in all of the program reaches, except for the South Cross Levee, as there is currently no recreational use of the area.

Sacramento River North Levee

Recreational uses of the areas along the Sacramento North Levee are quite diverse, and the majority of these uses are tied to the mature riparian forest that characterizes a large stretch of the levee. These uses include fishing, wildlife viewing, walking, bicycling, horse riding, and boating. Permanent loss of the woody vegetation on and within 15 feet of the Sacramento River North Levee would substantially reduce the quality of existing recreation activities in the area, and is therefore considered significant. No feasible mitigation is available to reduce this effect to a lesser level. This effect could occur under any of the flood alternatives proposed for the Sacramento River North Levee, which are adjacent levee raise, full levee raise, in-place levee raise, rock slope protection, sheet pile wall, slope flattening, slurry cutoff wall, closure, and jet grouting.

Effect REC-3 Finding— Sacramento River North Levee	With Mitigation
Significant	Significant and unavoidable—no feasible mitigation

Sacramento River South Levee

A narrow band of mature riparian forest currently exists on and within 15 feet of the waterside slope of the Sacramento River South Levee. This forest is enjoyed by recreationists for shade, wildlife viewing opportunities, and for its visual character. Permanent loss of the woody vegetation on and within 15 feet of the Sacramento River South Levee would substantially reduce the quality of existing recreation activities in the area, and is therefore considered significant. No feasible mitigation is available to reduce this effect to a lesser level. This effect could occur under most of the flood alternatives proposed for the Sacramento River South Levee, including adjacent levee raise, full levee raise, in-place levee raise, relief wells, rock slope protection, slope flattening, slurry cutoff

wall, stability berm. However, the finding for this effect would be different for a setback levee in this reach, and is explored below.

Effect REC-3 Finding—Sacramento River South Levee	With Mitigation
Significant	Significant and unavoidable—no feasible mitigation

Setback Levee on the Sacramento River South Levee

Construction of a setback levee in the Sacramento River South Levee reach would move the official levee (and vegetation maintenance requirements) landward, allowing the mature riparian vegetation on and near the waterside of the existing levee to remain. There would be very little long-term reduction in quality of existing recreation opportunities. This effect would be less than significant. No mitigation is required.

Effect REC-3 Finding—Setback Levee, Sacramento South Levee	With Mitigation
Less than significant	N/A

Port North Levee

Permanent loss of the woody vegetation on and within 15 feet of the Port North Levee would substantially reduce the quality of existing recreation activities in the area, specifically for boaters on the barge canal who use the mature riparian vegetation for fishing, shade, and wildlife-viewing. This effect is considered significant. No feasible mitigation is available to reduce this effect to a lesser level. This effect could occur under both of the flood alternatives proposed for the Port North Levee, which are a flood wall and a closure structure.

Effect REC-3 Finding—Port North Levee	With Mitigation
Significant	Significant and unavoidable—no feasible mitigation

Port South Levee

Many of the recreation activities that occur along the Port South Levee, especially those activities that occur at the barge canal access, rely on or are significantly enhanced by the presence of mature woody vegetation. Permanent loss of the woody vegetation on and within 15 feet of the Port South Levee would substantially reduce the quality of existing recreation activities in the area, and is therefore considered significant. No feasible mitigation is available to reduce this effect to a lesser level. This effect could occur under any of the flood alternatives proposed for the Port South Levee, which are flood wall, adjacent levee raise, full levee raise, in-place levee raise, slope flattening, slurry cutoff wall, and closure structure.

Effect REC-3 Finding—Port South Levee	With Mitigation
Significant	Significant and unavoidable—no feasible mitigation

DWSC West Levee

The DWSC West Levee is, in general, already maintained in a manner close to the new USACE standard for vegetation on levees, and full compliance with the policy would not require the removal of a substantial amount of woody vegetation. However, an adjacent levee raise and a full levee raise are proposed as flood protection alternatives along this levee stretch, each of which would require the levee footprint to be expanded and therefore extend the zone that must be maintained free of woody vegetation. This could result in the removal of areas of existing riparian forest, reducing the quality of existing recreation activities in the area, and is therefore considered significant. No feasible mitigation is available to reduce this effect to a lesser level.

Effect REC-3 Finding—DWSC West Levee	With Mitigation
Significant	Significant and unavoidable—no feasible mitigation

DWSC East Levee

Although there is little mature woody vegetation along the DWSC East Levee, the cottonwood and oak trees that do exist along the waterside berm are host to a large number of birds and other wildlife and provide popular spots for wildlife viewing. Removal of a large number of these trees to ensure compliance with USACE vegetation policy would substantially reduce the quality of existing wildlife viewing activities in the area, and would therefore be considered significant. This effect could occur under any of the proposed flood program alternatives along the DWSC East Levee, which are adjacent levee raise, full levee raise, in-place levee raise, relief wells, rock slope protection, sheet pile wall, slope flattening, and slurry cutoff wall.

Effect REC-3 Finding—DWSC East Levee	With Mitigation
Significant	Significant and unavoidable—no feasible mitigation

Yolo Bypass Levee

The Yolo Bypass Levee is, in general, already maintained in a manner close to the new USACE standard for vegetation on levees, and full compliance with the policy would not require the removal of a substantial amount of woody vegetation. However, a stability berm is proposed as a flood protection alternative along this levee stretch, which would require the levee footprint to be expanded and therefore extend the zone that must be maintained free of woody vegetation. This could result in the removal of large areas of existing riparian forest, substantially reducing the quality of existing recreation activities in the area, and is therefore considered significant. No feasible mitigation is available to reduce this effect to a lesser level.

Effect REC-3 Finding—Yolo Bypass Levee	With Mitigation
Significant	Significant and unavoidable—no feasible mitigation

Sacramento Bypass Levee

The Sacramento Bypass Levee is, in general, already maintained to the new USACE standard for vegetation on levees, and full compliance with the policy would not require the removal of much additional woody vegetation. However, three flood protection alternatives (slope flattening, seepage berm, and stability berm) are proposed for the Sacramento Bypass Levee that would require the

levee footprint to be expanded landward and therefore extend the zone that must be maintained free of woody vegetation. This may require removal of some mature trees from the CHP Academy EIP project area. However, because the trees are part of an already marginal view of CHP Academy facilities and are currently inaccessible to visitors due to fencing, and because the Sacramento Bypass Levee is not known as a wildlife viewing spot, this effect would be less than significant. No mitigation is required.

Effect REC-3 Finding—Sacramento Bypass Levee	With Mitigation
Less than significant	N/A

Effect REC-4: Permanent Loss of Recreation Facilities or Opportunities

Some flood program alternatives could require full or partial removal of formal recreation facilities along the Sacramento River North, Sacramento River South, and Port South reaches. This could occur if the levee footprint is expanded into an existing park or facility, or if a facility on the levee would be permanently affected by the flood alternative. This effect is discussed as it relates to each reach in the Affected Reaches section below.

Program Alternatives Associated with This Effect

Implementation of the following flood program alternatives could cause Effect REC-4:

Program	Alternative	
Flood	▪ Flood wall	▪ Relief wells
	▪ Levee raise (in place)	▪ Slope flattening
	▪ Levee raise (adjacent)	▪ Stability berm
	▪ Levee raise (full)	▪ Setback levee

Affected Reaches

Sacramento River North Levee

An adjacent levee raise, full levee raise, or slope flattening on the Sacramento River North Levee would require the levee footprint to be expanded landward. Bryte Park, a West Sacramento community park, sits right at the landside toe of the existing levee. Expansion of the levee footprint could intrude into the park, possibly requiring the removal of a portion of the running track and soccer field. WSAFCA has committed to rebuilding all formal park facilities removed during construction activities (see the environmental commitment to rebuild affected formal park facilities described in Section 2.9, Chapter 2, and Alternatives). With implementation of this environmental commitment, the running track and soccer field would be rebuilt after construction of levee alternatives, and there would be no permanent loss of recreation opportunities. This effect would be less than significant. No mitigation is required.

Effect REC-4 Finding—Sacramento River North Levee	With Mitigation
Less than significant	N/A

Sacramento River South Levee

An adjacent levee raise, full levee raise, or slope flattening on the Sacramento River South Levee would require the levee footprint to be expanded landward, and relief wells would require small areas on the landside of the levee to be allotted to the wells. This could permanently encroach upon two informal recreation areas: the Honda Hills and the Bees Lakes area, both described above. The Honda Hills area is used by riders of off-highway vehicles, equestrians, and pedestrians and the Bees Lakes area is used by wildlife viewers and paintball enthusiasts.

Because these areas are not formal recreation facilities, and because any land permanently removed to accommodate an enlarged levee footprint or relief wells would be a small fraction of the Honda Hills' 640-acre total area and the Bees Lakes 23-acre total area, permanent effects would be less than significant. No mitigation is required.

Effect REC-4 Finding—Sacramento River South Levee	With Mitigation
Less than significant	N/A

Setback Levee on the Sacramento River South Levee

A setback levee in the Sacramento River South Levee stretch would require construction of an entirely new levee embankment some distance landward of the existing levee. Depending on placement of the setback levee, this may affect the Honda Hills and Bees Lakes areas, which are used for informal recreational purposes as described above.

Construction of a setback levee would occur west of the Bees Lakes. This may lead to occasional inundation of the area during high flow events in the Sacramento River, but the area would remain intact and long-term effects on recreation opportunities in the area would be minimal.

Construction of a setback levee could permanently affect the Honda Hills area, causing a portion of the land to be lost to the new levee footprint. However, because the current recreational use of the area is unauthorized, and because a formal off-highway vehicle park exists within the region (Prairie City State Vehicular Recreation Area), this effect is considered less than significant.

As described in Chapter 2, Alternatives, the City of West Sacramento plans to convert the Honda Hills area to a formal recreation area (Stone Lock District). Construction of all or a portion of this recreation area is addressed as a potential part of the program. Plans for the park would need to be modified to accommodate the setback levee if one were to be constructed. Although the plans for the Stone Lock District may need to be modified, this effect is considered less than significant, as the new setback levee and waterside areas could be compatibly incorporated into the design of the park. No mitigation is required.

Effect REC-4 Finding—Setback Levee, Sacramento River South Levee	With Mitigation
Less than significant	N/A

Stability Berm on the Sacramento River South Levee

Construction of a stability berm along the Sacramento River South Levee would require the levee footprint to be expanded landward. The Honda Hills and Bees Lakes areas sit right at the toe of the existing levee, as described above in the Setting section. These areas are used for informal

recreational pursuits. Depending on the width of the berm necessary to meet the structural needs of the levee, some of the land currently used for recreational pursuits in these areas could be lost to the berm's footprint. Although the Honda Hills and Bees Lakes areas offer unique opportunities within the City for off-highway vehicle use, wildlife viewing, and paintball enthusiasts, they are not formally recognized recreation areas and recreational use of these areas is not authorized. Loss of these areas to non-recreational use would therefore be less than significant. No mitigation is required.

As described in Chapter 2, Alternatives, the City plans to convert the Honda Hills area to a formal recreation area (Stone Lock District), and the Bees Lakes area to an official recreation area. Construction of all or a portion of these parks are addressed programmatically. Plans for the parks would need to be modified to accommodate the stability berm if one were to be constructed. Although the plans for the Stone Lock District and the Bees Lakes area may need to be modified, this effect would be less than significant, as the new stability berm could be compatibly incorporated into the design of the parks. No mitigation is required.

Effect REC-4 Finding—Stability Berm, Sacramento River South Levee	With Mitigation
Less than significant	N/A

Port South Levee

An adjacent levee raise, full levee raise, in-place levee raise, or slope flattening on the Port South Levee would require all features on the levee crown to be removed. In the case of an adjacent levee raise, full levee raise, or slope flattening, all features on the landside of the levee would also need to be removed to accommodate the landward expansion of the levee footprint. This could have permanent effects on two recreation areas: the Barge Canal Recreational Access, which is located on top and on the waterside of the levee, and the informal recreation area known as the Honda Hills, both described above.

Because the Honda Hills area is not a formal recreation facility, and because any land permanently removed to accommodate an enlarged levee footprint would be a small fraction of the Honda Hills' 640-acre total area, permanent effects on the Honda Hills would be less than significant. See the above discussion of effects related to construction of a stability berm on the Sacramento River South Levee for an exploration of effects of levee expansion on park planning efforts.

The Barge Canal Recreational Access is a formal, City of West Sacramento facility. It is a narrow, linear park, located exclusively on a 0.25-mile swath of the Port South Levee just west of Jefferson Boulevard. Levee raising or slope flattening in this area likely would require the removal of all infrastructure related to this facility to accommodate construction activities. Because the Barge Canal Recreational Access is a popular, City-sanctioned fishing spot, and because the boat ramp there provides the only public boat access to the barge canal or DWSC, the loss of this facility would significantly affect recreation opportunities in the community. However, WSAFCA has committed to rebuilding all formal park facilities removed during construction activities (see the environmental commitment to rebuild affected formal park facilities described in Section 2.9 of Chapter 2, Alternatives). With implementation of this environmental commitment, the Barge Canal Recreational Access would be rebuilt after construction of levee alternatives and there would be no permanent loss of recreation opportunities. This effect would be less than significant. No mitigation is required.

Effect REC-4 Finding—Port South Levee	With Mitigation
Less than significant	N/A

Flood Wall on the Port South Levee

A flood wall is proposed as one of the flood program alternatives on the Port South Levee. Permanent presence of a flood wall would restrict recreation activities along the Port South Levee, most significantly fishing and boating. A flood wall would permanently block access to the boat ramp located at the Barge Canal Recreational Access, and, depending upon the height of the wall and potential disabilities of visitors, could prevent anglers from accessing the banks of the barge canal. Because the Barge Canal Recreational Access is a popular, City-sanctioned fishing spot, and because the boat ramp there provides the only public boat access to the barge canal or DWSC, this permanent effect is considered significant. Implementation of Mitigation Measure REC-MM-2 would reduce this effect to a less-than-significant level.

Effect REC-4 Finding—Flood Wall, Port South Levee	With Mitigation
Significant	Less than significant

Mitigation

Mitigation Measure REC-MM-2: Preserve Access to Barge Canal Recreation Access

WSAFCA will ensure that formal recreational access to the barge canal is permanently preserved. For example, this could be achieved by using closures instead of a floodwall at the Barge Canal Recreational Access. The closures would only need to be in place on the levee when the city is threatened by high water. At other times of the year, the closures would be removed and stored nearby to allow for full recreation access to the waterfront.

Yolo Bypass Levee

Construction of a stability berm on the Yolo Bypass Levee would require the levee footprint to be expanded landward. The Roland Hensley Bike Park, a City of West Sacramento mini park, sits right at the landside toe of the existing levee, north of I-80. This park serves as a staging area for riders on the Yolo Causeway Bicycle Path, and provides a connection between the path and West Capitol Avenue. Riders can access West Capitol Avenue through the Roland Hensley Bike Park parking lot, or via a connector path that parallels the toe of the levee for approximately 1,200 feet. A stability berm in that area would extend the levee footprint into the park and connector path. Depending on the width of the berm, the park and connector path may need to be completely removed.

The Yolo Causeway Bicycle Path is a heavily used regional recreation and commuter corridor, and the only access to this corridor is through Roland Hensley Bike Park. Removal of the park would significantly affect regional recreation opportunities, as it would eliminate access to and from the Yolo Causeway Bicycle Path. However, WSAFCA has committed to rebuilding all formal park facilities removed during construction activities (see the environmental commitment to rebuild affected formal park facilities described in Section 2.9 of Chapter 2, Alternatives). With implementation of this environmental commitment, WSAFCA will ensure that a safe bicycle route connecting the Yolo Causeway Bicycle Path to West Capitol Avenue, along with replacement of existing bike park amenities are constructed after levee alternatives are complete, ensuring that

there is no significant permanent loss of recreation opportunities. This effect would be less than significant. No mitigation is required. Temporary effects on the Yolo Causeway Bicycle Path are discussed above under Effect REC-1.

Effect REC-4 Finding—Yolo Bypass Levee	With Mitigation
Less than significant	N/A

Effect REC-5: Temporary Disruption of Recreational Boating Activities during Construction

Placement of rock slope protection may require in-channel construction activities that could temporarily disrupt recreational boating and personal watercraft use. If the bank protection design incorporates a rock bench, in-channel construction activities are likely to occur. Rock slope protection is proposed as a flood program alternative along the Sacramento River North and Sacramento River South, DWSC West, and DWSC East Levees. This effect is discussed as it relates to each reach in the Affected Reaches section below.

Program Alternatives Associated with This Effect

Construction of rock slope protection could cause Effect REC-5.

Program	Alternative
Flood	▪ Rock slope protection

Affected Reaches

Sacramento River North and Sacramento River South Levees

As described in the Setting section above, the Sacramento River is a popular year-round recreation boating corridor. Temporary disruption of recreational boating would result from the presence of construction vehicles, equipment, and personnel in and adjacent to the Sacramento River, as well as temporary construction effects on channel water quality (i.e., increased turbidity from suspended materials).

The disruption of recreational boating in the area would be temporary and WSAFCA would implement the environmental commitment to reduce construction-related effects on navigation (as described in Section 2.9, Chapter 2, and Alternatives). This environmental commitment includes measures to ensure that:

- construction will not occur during major summer holiday periods; and
- warning signs and buoys will be posted at, upstream of, and downstream of all construction equipment, sites, and activities.

Therefore, this effect would be less than significant. No mitigation is required.

Effect REC-5 Finding— Sacramento River North and Sacramento River South Levees	With Mitigation
Less than significant	N/A

DWSC West and DWSC East Levees

As described in the Setting section above, the calm waters of the DWSC provide a unique recreation opportunity for non-motorized boaters, regional rowing clubs, and local sailing and outboard motor clubs. Temporary disruption of recreational boating would result from the presence of construction vehicles, equipment, and personnel in and adjacent to the DWSC, as well as temporary construction effects on channel water quality (i.e., increased turbidity from suspended materials).

The disruption of recreational boating in the area would be temporary and WSAFCA would implement the environmental commitment to reduce construction-related effects on navigation (described in Section 2.9, Chapter 2, Alternatives). Therefore, this effect would be less than significant. No mitigation is required.

Effect REC-5 Finding—DWSC West and DWSC East Levees	With Mitigation
Less than significant	N/A

Effect REC-6: Long-Term Increase in Recreation Opportunities

A number of new recreation facilities are proposed for construction in the study area. As described in Chapter 2, Alternatives, these include trails, riverside parks, developed water access, and special projects. These new facilities would constitute a substantial increase in recreation opportunities for the City of West Sacramento, and would advance the policies of the following planning documents:

- *City of West Sacramento General Plan*
- *City of West Sacramento Parks Master Plan*
- *Sacramento Riverfront Master Plan*
- *Southport Design Guidelines*
- *Triangle Specific Plan*
- *Washington Specific Plan*
- *West Sacramento Bicycle and Pedestrian Path Master Plan*
- *Yolo County General Plan*

Program Alternatives Associated with This Effect

Implementation of any of the recreation program alternatives would cause Effect REC-6:

Program	Alternative	
Recreation	▪ Trails	▪ Developed water access
	▪ Riverside parks	▪ Special projects

Affected Reaches

Recreation alternatives are proposed along the entire levee reaches except for the DWSC West Levee. Effects specific to each reach are described below. This effect is considered beneficial for all reaches.

Sacramento River North Levee

A number of new recreation facilities are proposed for construction along the Sacramento River North Levee under the program. These include, among other improvements, docks and fishing piers, formal park facilities, habitat zones, a continuous recreation trail, a public plaza, an extension of the Riverwalk Promenade, and improvements to Bryte Park. These new park facilities would constitute a substantial increase in recreation opportunities for the city, and would advance the policies of the planning documents listed above. This effect is considered beneficial.

Sacramento River South Levee

The recreation alternatives proposed along the Sacramento River South Levee include recreation facilities at the Stone Lock District, Southport Community Park/River Park, and a recreation corridor running the length of the levee reach. The construction of active and passive recreation facilities at the Stone Lock District would convert the waterfront area from an informally used fishing, walking, and equestrian area to a more formal park-like setting. Eventual recreation facilities may also include a rowing and boating center, a marina, an amphitheater and festival venue, trails, and fishing piers. Formal park development and presence of park employees would increase the safety of the area. These new and upgraded recreation facilities would constitute a substantial increase in recreation opportunities for the city, and would advance the policies of the planning documents listed above. This effect is considered beneficial.

Port North Levee

Two new recreation facilities are proposed for construction along the Port North Levee under the program. As described in Chapter 2, Alternatives, these are active and passive recreational facilities at the Stone Lock District and a recreation corridor between the Sacramento River and Lake Washington Boulevard. These new recreation facilities would constitute a significant increase in recreation opportunities for the city, and would open up a large area for public access that is currently in private ownership. Construction of these facilities would also advance the policies of the planning documents listed above. This effect is considered beneficial.

Port South Levee

A number of new recreation facilities are proposed for construction along the Port South Levee under the program. These include a recreation corridor along the levee running from the Sacramento River to Lake Washington Boulevard, the Stone Lock District, and upgrades to the Barge Canal Recreational Access. The construction of passive and active recreational facilities at the Stone Lock District would convert the waterfront area from an informally used fishing, walking, and equestrian area to a more formal park-like setting. Eventual recreation facilities may include a rowing and boating center, a marina, an amphitheater and festival venue, trails, and fishing piers. Formal planning and presence of park employees would increase the safety of the area. These new and upgraded recreation facilities would constitute a significant increase in recreation opportunities for the City of West Sacramento, and would advance the policies of the planning documents listed above. This effect is considered beneficial.

South Cross Levee

A paved pedestrian and bicycle trail connecting the Sacramento River South Levee to the DWSC East Levee is proposed for construction atop the South Cross Levee under the program. This segment is part of the larger Recreational Corridor 5 trail proposed in the Parks Master Plan, which, when

combined with Recreational Corridors 1 and 4, would provide a continuous bike/pedestrian loop around the entire Southport area. Acquisition of a public right-of-way and construction of this levee-top trail would significantly improve recreation corridor connectivity, as the South Cross Levee is currently closed to public access. It would also advance the policies of the planning documents listed above. This effect is considered beneficial.

DWSC East Levee

Although the DWSC East Levee is currently used as a bike and pedestrian trail, it is private property and public access is technically considered trespassing. An official public right-of-way featuring a pedestrian and bicycle trail with water access trails and landings where appropriate is proposed for acquisition and construction atop the DWSC East Levee as part of the program. This segment is part of the larger Recreational Corridor 5 trail proposed in the Parks Master Plan, which, when combined with Recreational Corridors 1 and 4, would provide a continuous bike/pedestrian loop around the entire Southport area. Acquisition of a public right-of-way and construction of this segment of Recreational Corridor 5 would significantly improve recreation corridor connectivity and expand officially sanctioned recreation opportunities in the Southport area. It would also advance the policies of the planning documents listed above. This effect is considered beneficial.

Yolo Bypass Levee and Sacramento Bypass Levee

A paved pedestrian and bicycle trail is proposed for acquisition and construction atop the Yolo Bypass and Sacramento Bypass Levees as part of the program. Although this segment is not part of the larger recreational corridor system proposed in the Parks Master Plan, this area is currently underutilized and construction of a trail in this area would improve recreation corridor connectivity and expand recreation opportunities in West Sacramento. It would also advance the policies of some of the planning documents listed above. This effect is considered beneficial.

Effect REC-6 Finding	With Mitigation
Beneficial	N/A

Section 3.16
Utilities and Public Services

3.16.1 Introduction

This section describes the regulatory and environmental setting for utilities and public services, the effects on utilities and public services that would result from the program, and the mitigation measures that would reduce these effects.

The key sources of data and information used in the preparation of this section are listed and briefly described below.

- City of West Sacramento website (www.cityofwestsacramento.org)
- Yolo County website (ww.yolocounty.org)
- Communications with Yolo County Planning Department

3.16.2 Affected Environment

3.16.2.1 Regulatory Setting

3.16.2.1.1 State

California Public Utilities Commission

The California Public Utilities Commission (CPUC) regulates privately owned telecommunications, electric, natural gas, water, railroad, rail transit, and passenger transportation companies. CPUC is responsible for ensuring that California utility customers have safe, reliable utility service at reasonable rates, protecting utility customers from fraud, and promoting the health of California's economy. CPUC establishes service standards and safety rules and authorizes utility rate changes. CPUC enforces CEQA compliance for utility construction. CPUC also regulates the relocation of power lines by public utilities under its jurisdiction, such as The Pacific Gas and Electric Company (PG&E). CPUC works with other state and Federal agencies in promoting water quality, environmental protection, and safety.

California Integrated Waste Management Act

In 1989, Assembly Bill 939 (AB 939), known as the Integrated Waste Management Act, was passed into law. Enactment of AB 939 established the California Integrated Waste Management Board and set forth aggressive solid waste diversion requirements. Under AB 939, every city and county in California is required to reduce the volume of waste sent to landfills by 50% through recycling, reuse, composting, and other means. AB 939 requires counties to prepare a Countywide Integrated Waste Management Plan (CIWMP). An adequate CIWMP contains a summary plan that includes goals and objectives, a summary of waste management issues and problems identified in the incorporated and unincorporated areas of the county, a summary of waste management programs

and infrastructure, existing and proposed solid waste facilities, and an overview of specific steps that would be taken to achieve the goals outlined in the components of the CIWMP.

3.16.2.1.2 Local

City of West Sacramento

City of West Sacramento General Plan

The *City of West Sacramento General Plan Policy Document* defines the policies and objectives governing City responsibilities for public utilities and services.

Stormwater Drainage

City of West Sacramento General Plan Section IV, Goal C (City of West Sacramento 2004a) states that the City will maintain an adequate level of service in the storm drainage system to accommodate runoff from existing and future development and to prevent property damage from flooding. The policies to accomplish this goal are listed below.

1. Where practical and economical, the City shall upgrade existing drainage facilities as necessary to correct localized flooding problems.
2. The City shall continue to expand and develop storm drainage facilities to accommodate the needs of existing and planned development.
3. The City shall, through a combination of drainage improvement fees and other funding mechanisms, ensure that new development pays its fair share of the costs of drainage system improvements.
4. The City shall cooperate with other responsible agencies in ensuring that levees surrounding the city are maintained and improved to provide a minimum 200-year flood protection.

Water

The City provides water to its constituents in accordance with the *City of West Sacramento General Plan*, Section IV, Goal A. (City of West Sacramento 2004a) This goal states the City will maintain an adequate level of service in the water system to meet the needs of existing and future development. The policies associated with this statute follow.

1. The City shall continue to use treated surface water from the Sacramento River as the principal source of domestic water for the city, relying on treated groundwater only to supply the port pressure zone and as an emergency backup to the surface water source. The City shall pursue as expeditiously as possible, acquisition of additional surface water rights necessary to accommodate water demand.
2. The City shall continue to expand and develop water treatment, distribution, and storage facilities to accommodate the needs of existing and planned development.
3. To minimize the need for the development of new water sources and facilities and to minimize sewer flows, the City shall promote water conservation both in City operations and in private development.
4. The City shall replace or repair old, leaking water lines as financially feasible.

5. The City shall ensure the provision of adequate fire-flow rates in all new development.
6. The City shall maintain fire hydrants.
7. The City shall, through a combination of water development fees and other funding mechanisms, ensure that new development pays its fair share of the costs of water system improvements.

The Bryte Bend Treatment Plant is responsible for treatment of City's water and for reporting standards and findings regarding the City's drinking water to the California State Department of Health Services, Drinking Water Program. The Bryte Bend Water Treatment Plant Laboratory:

- monitors drinking water quality to ensure it is of a consistently high quality,
- provides laboratory services necessary to support the operating and monitoring requirements for the water treatment plant,
- responds to consumer water quality concerns,
- monitors water quality of the distribution system and watershed, and
- provides services to environmental programs.

Wastewater

The City of West Sacramento manages the wastewater according to the *City of West Sacramento General Plan*, Section IV, Goal B. The City states it will maintain an adequate level of service in the City's sewage collection and disposal system to meet the needs of existing and future development.

Solid Waste

Solid waste disposal is provided by Yolo County and governed by the *City of West Sacramento General Plan*, Section IV, Goal D in close consultation with Yolo County Department of Public Works. This plan defines the programs for recycling and reuse, resource recovery, and disposal. The City commits to provide for the collection and disposal of solid waste while minimizing the generation of waste (City of West Sacramento 2004a).

Public Services

The placement of public services in the City is authorized by the City of West Sacramento Planning Department in accordance the goals and policies established in the *City of West Sacramento General Plan*, Section IV. The City of West Sacramento Public Works Department is responsible for operating and maintaining city roads, which serve as emergency vehicle routes.

Solano County

Solano County General Plan

The *Solano County General Plan* contains the following goals and policies that regulate public services and utilities, as they relate to the program, within Solano County:

PF.G-1: Provide adequate public services and facilities to accommodate the level of development planned by the County.

PF.G-2: Ensure that residents throughout Solano County have access to essential public facilities and services.

PF.G-3: Provide effective and responsive fire and police protection, and emergency response service.

PF.P-4: Ensure that adequate land is set aside within the unincorporated county for public facilities to support future needs.

PF.P-38: Ensure accessible and cost-effective fire and emergency medical service throughout the county. Facilitate coordination among city and county fire agencies and districts to improve response times, increase services levels, provide additional training, and obtain essential equipment.

PF.P-39: Identify and require incorporation of fire protection and emergency response measures in the review and approval of new projects.

Stormwater and Drainage

These floodplain zones are defined by FEMA. Staff in the Department of Resource Management will evaluate projects in dam inundation areas on a case-by-case basis using the current data available to them.

- HS.P-1 through HS.P-11

Wastewater

Solano County in the jurisdiction of two RWQCBs: the San Francisco Bay RWQCB in the western county and the Central Valley RWQCB in the east. The State Water Board was created in 1967 to allocate water resources and to protect water quality. The mission of the RWQCBs is to develop and enforce water quality objectives and implementation plans to best protect the state's waters, recognizing local differences in climate, topography, geology, and hydrology.

- Policies PF.P-21through PF.P-22

Solid Waste

The CIWMP for Solano County was developed in response to Assembly Bill 75 (AB 75), which required each state agency and large state facility to develop such a plan. This legislation requires each county to report annually on the implementation of its CIWMP.

- Policies PF.P-23 through PF.P-31

Public Services

CPUC regulates privately owned telecommunications, electric, natural gas, water, railroad, rail transit, and passenger transportation companies, in addition to authorizing video franchises. The Federal Energy Regulatory Commission is an independent agency that regulates the interstate transmission of electricity, natural gas, and oil.

- PF.P-49 through PF.P-52

3.16.2.2 Environmental Setting

This section discusses the existing conditions related to utilities and public services in the study area.

3.16.2.2.1 Utilities and Service Systems

HDR, Inc. performed a preliminary assessment and review of known aboveground and underground utilities in the study area (Appendix D). The assessment was completed by obtaining encroachment permits from the State of California Central Valley Flood Protection Board (CVFPB) that describe underground and aboveground utilities which occur within, on top of, or above the current levee footprint. Overhead utilities (power lines and telephone lines) and underground utilities (telephone and fiber optic conduits, communication cables, and pipelines) occur in the study area. The listed utilities may not be in compliance with the CVFPB and USACE utility placement standards within levees. Please see Appendix D for a table listing known utilities in the study area.

Electric Power Transmission

Electricity for the study area is provided by PG&E. Power transmission facilities have developed parallel to population growth in various communities within the study area. Many power-generating facilities are found in the study area.

Natural Gas

Natural gas pipelines exist throughout the study area. These pipelines are owned and operated by PG&E. These pipelines are usually 6- to-8-inch high-pressure gas lines that provide natural gas to the residences and businesses in the study area. Propane is delivered by tanker trucks to users as necessary and is stored in individual propane tanks.

Communications

SBC Communications Inc., Pacific Bell, MCI, Electric Lightwave, and XO Communications provide communication services in the study area. SBC Communications provides its services through underground fiber trunk lines and overhead lines attached to poles. The communication lines typically are aligned parallel to roadways and then traverse the roadways to supply individual service units.

A network of various telephone companies, cellular communication companies, and cable companies also service the study area. New service to specific sites is accomplished on a case-by-case basis.

Water

The city's main water source is the Sacramento River. The intake structure is located at Bryte Bend, upstream of the confluence of the Sacramento and American Rivers. Water withdrawn from the Sacramento River is treated at the Bryte Bend Water Treatment Plant, which is operated 24 hours a day by state- certified water treatment plant operators.

Stormwater and Drainage

Stormwater drainage networks consist of both natural and human-made conveyance systems to collect, convey, and store runoff resulting from a storm event. The City manages the stormwater drainage system in the urban areas and in some rural areas.

Impervious surfaces in the study area are limited to roads, other small sections of pavement, urban residential and business structures, and rural residential and agricultural structures. Stormwater in

the agricultural portions of the study area are drained primarily by overland flow into human-made ditches, natural drainage swales, and watercourses that discharge into waterways.

Wastewater

Wastewater treatment in the study area is handled by the City of West Sacramento Wastewater Treatment Plant, built in 1948 and expanded in 1977 and 1988. A major improvement program took place during the early 1990s. The plant uses a secondary treatment activated sludge process with an anoxic selector. The average daily flow is 5.5 million gallons per day.

Solid Waste

Solid waste disposal is provided and governed by the *City of West Sacramento General Plan* in close consultation with Yolo County Department of Public Works. This plan defines the programs for recycling and reuse, resource recovery, and disposal. Solid waste currently is disposed of at the Yolo County Central Landfill located in the city of Davis. For 2009, the remaining capacity is 37,108,000 cubic yards.

3.16.2.2.2 Public Services

Fire Protection

The City's Fire Department has the mission of protecting life, environment, and property within the city of West Sacramento. To effectively complete this mission, the Fire Department has five fire stations throughout the city, each of which houses one front line fire engine equipped to handle a variety of emergency calls. The five fire stations operate 24 hours a day, 7 days a week, with a combined staffing of 19 personnel on duty. Firefighters work 24-hour tours of duty. The Fire Department is divided into three major units: Emergency Services, Fire Prevention/Hazardous Materials, and Administration.

Police Protection

According to the City's web site, the West Sacramento Police Department is committed to providing quality service to the community and its guests through maintaining order, fostering a sense of security, enforcing the laws of the city and state, and supporting the Constitutions of the United States and the State of California.

The Police Department provides a full range of police services to the residents of West Sacramento 24 hours a day, 7 days a week. The department is responsible for patrolling city neighborhoods, responding to calls for service, investigating crime and arresting offenders, and working closely with the community to identify and solve problems of crime and neighborhood disorder. They also provide educational programs to assist citizens with making their communities safe and enjoyable places to live.

The Police Department is organized into three offices: Administration, Investigations (which includes the Code Enforcement Division), and Operations. West Sacramento police officers service a population of 47,782 (California Department of Finance 2009) and patrol 23.3 square miles.

The Police Department is staffed with 75 sworn officers and 39 civilian full-time employees. Other positions include part-time police officers, parking enforcement officers, reserve police officers, and volunteers.

Emergency Medical Services

No hospitals are located within the city of West Sacramento. The nearest hospital is Sutter General Hospital, which is 3.7 miles from West Sacramento at 29th Street in Sacramento.

3.16.3 Environmental Consequences

This section describes the utilities and public services effects associated with the program. It describes the methods used to determine the effects of the program and lists the thresholds used to conclude whether an effect would be significant. Measures to mitigate (i.e., avoid, minimize, rectify, reduce, eliminate, or compensate for) significant effects accompany each effect discussion.

3.16.3.1 Assessment Methods

Effects on utilities and public services were evaluated based on the duration and extent to which such services would be affected as well as the ability of a service provider to continue to provide a level of service that could meet the needs of an affected community. The evaluation assumed modifications to levees would occur in phases and when floods were unlikely.

The following process was followed to determine whether effects on utilities and public services would be considered significant:

- review of relevant documents and websites to obtain information regarding known public services and utilities in the study area,
- analysis of geographic map research to determine locations of existing utilities and public services for program components, and
- telephone calls and e-mail correspondence to area utility/service providers.

3.16.3.2 Determination of Effects

Significance criteria for identifying program effects on utilities and public services are based on Appendix G of the State CEQA Guidelines. Utilities and public services effects are based on the displacement or modification of facilities and services because of either water-related facility development or economic stimulation. Utility and public service effects are considered if implementation of the program would:

- require the construction or expansion of electrical or natural gas transmission or distribution facilities;
- require the construction or expansion of a water conveyance or wastewater treatment facility or require new or expanded water supply entitlements;
- require the construction of new or expanded stormwater drainage facilities;
- require the construction or expansion of wastewater treatment facilities;
- cause the capacity of a solid waste landfill to be reached sooner than it would without the program;
- require the construction or expansion of communications facilities (telephone, cell, cable, satellite dish);

- significantly affect public utility facilities that are located underground or aboveground along the local roadways from program construction activities;
- create an increased need for new fire protection, police protection, or ambulance services or significantly affect existing emergency response times or facilities; or
- intersect with major infrastructure components, such as bridges or overpasses, requiring relocation of the components.

3.16.3.2.1 Effects Assumptions

The following assumptions are made as part of the analysis of effects on Utilities and Public Services:

- Implementation of the proposed program is not expected to create additional demand for electricity or natural gas and would not require the construction or expansion of electrical or natural gas transmission lines or public utilities.
- Implementation of the program would not require the construction or expansion of wastewater treatment facilities, nor would it require the relocation of major infrastructure.
- In addition to the effects listed below, Effect TN-4: Increase Emergency Response Times, discussed in Section 3.5, Transportation and Navigation, also applies to this resource.

3.16.3.3 Effects and Mitigation Measures

3.16.3.3.1 No Action Alternative

To recap from Chapter 2, Alternatives, the No Action Alternative is the continuation of the existing deficiencies along the nine levee reaches and absence of levee alternatives to increase the level of protection. Current levee operations and maintenance activities would continue; however, no ground-disturbing activities related to construction or program maintenance would occur and no utilities or service systems would be interrupted or damaged.

Under the No Action Alternative, there would be a continued potential for levee failure that could cause inundation from high flows and destruction or damage to utility lines, natural gas supply lines, and water or wastewater piping or facilities, all of which could lead to widespread contamination, temporary power outages, and interruptions of other utilities in the study area and surrounding areas. Effects on the water supply system could be particularly severe, as a single break in a water delivery pipe or main could contaminate the entire city's water supply. All breaks and leaks would need to be repaired and the pipes in every building would need to be flushed to remove contamination before residents and businesses could rely on safe water. Depending on the severity and location of the flooding and contamination, this effort could take a significant amount of time.

Varying levels of damage could be done to public service structures as well, causing delays in fire protection, police protection or emergency medical assistance. A major flood event could also stress the region's emergency response and hospital services, as the likelihood of injury resulting from a flood event is high, and evacuees may not have access to their regular medications. However, the potential for such an occurrence is uncertain, and the magnitude and duration of any related risks cannot be predicted. Because the effects of a levee failure are unpredictable, a precise determination of significance is not possible and cannot be made.

3.16.3.3.2 Proposed Flood and Recreation Alternatives

Effect PUB-1: Damage of Public Utility Infrastructure and Disruption of Service

Construction of program flood and recreation alternatives could necessitate the relocation of utility infrastructure, which could result in temporary loss of service. Existing infrastructure such as telephone lines, natural gas lines, fiber optic, cable and other utility lines could be underground or overhead at a project site.

Utility infrastructure could require significant actions to repair, relocate, or replace depending on specific construction activities occurring at each site. Additionally, program construction could necessitate that existing utilities be taken off line or could cause accidental damage to identified and unidentified infrastructure. Because the potential exists for damage and service interruptions to existing utilities both identified and unidentified, this potential construction effect would be considered significant. Mitigation Measure PUB-MM-1 would reduce these potential effects to a less-than-significant level.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause Effect PUB-1:

Program	Alternative	
Flood	▪ Levee raise (adjacent) ▪ Levee raise (in place) ▪ Levee raise (full) ▪ Rock slope protection ▪ Jet grouting ▪ Seepage berm ▪ Closure ▪ Setback levee	▪ Flood wall ▪ Slurry cutoff wall ▪ Relief wells ▪ Interior drain ▪ Slope flattening ▪ Sheet pile wall ▪ Stability berm
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

Although different flood and recreation alternatives are proposed for the reaches, Effect PUB-1 could occur in all the program reaches: Sacramento River North, Sacramento River South, Port North, Port South, South Cross, DWSC East and West, Sacramento Bypass, and Yolo Bypass Levee reaches.

Effect PUB-1 Finding	With Mitigation
Significant	Less than significant

Mitigation

Mitigation Measure PUB-MM-1: Verify Utility Locations, Coordinate with Utility Providers, Prepare a Response Plan, and Conduct Worker Training

The program proponent will ensure the following measures are implemented to avoid and minimize potential damage to utility and service disruptions during construction. Implementing these measures will help ensure existing utilities are not damaged and that service interruptions are minimized.

- Obtain utility excavation or encroachment permits as necessary before initiating any work with the potential to affect utility lines, and include all necessary permit terms in construction contract specifications.
- Before starting construction, coordinate with utility providers in the area to locate existing lines. Avoid the relocation of utilities when possible. Provide notification of potential interruptions in services to the appropriate agencies.
- Before starting construction, verify utility locations through field surveys and Underground Service Alerts. Clearly mark any buried utility lines in the area of construction before any earthmoving activity.
- Before starting construction, prepare a response plan to address potential accidental damage to a utility line. The plan will identify chain-of-command rules for notifying authorities and appropriate actions and responsibilities to ensure the safety of the public and the workers. Contractors will conduct worker training to respond to these situations.
- Stage utility relocations to minimize service interruptions.

Effect PUB-2: Exceed the Capacity or Shorten the Lifespan of Local Solid Waste Landfills as a Result of Construction

Implementation of the proposed program may generate large quantities of levee material that would require disposal. A portion of the material could be disposed of on site and used for new levee construction, as long as it is suitable material. Disposal of the soil material would occur if site conditions do not allow for on-site disposal, soil characteristics make it infeasible for reuse as levee material, or the soil is determined to have contaminants that would require appropriate disposal. A conservative estimate for the amount of soil to be disposed of as part of the program implementation is 3 million to 5 million cubic yards. Soil disposed as part of the program would likely be transported to the Yolo County Central Landfill; however, the location of the landfill used for disposal of spoil material and other construction-related waste may be determined by the construction contractor at the time of construction activity based on capacity, type of waste, and other factors. Only those landfills determined to have the ability to accommodate the construction disposal needs of the individually proposed projects would be used.

As of fall 2009, the remaining capacity for the Yolo County Central Landfill is 37,108,000 cubic yards. Some of the disposed soils may be deemed suitable by the Yolo County Central Landfill for other beneficial uses. These soils would only be temporarily stored at the landfill and would not have an effect on its overcall capacity. The current landfill closure projection is in 2070, which takes into account disposal growth rate, including both beneficial and non-beneficial soil materials. Assuming all of the estimated 3 million to 5 million cubic yards of soil would require permanent disposal, program implementation would represent 8% of the remaining capacity of the Yolo County Central

Landfill. However, the option of on-site disposal or beneficial re-use is likely to reduce the cubic yards of soil that require permanent disposal. These facts combined with the fact that the landfill has sufficient capacity remaining throughout the projected life of the program (15 to 20 years), would make this effect less than significant. No mitigation is required. (Borrego pers. comm.)

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause Effect PUB-2:

Program	Alternative	
Flood	▪ Levee raise (adjacent) ▪ Levee raise (in place) ▪ Levee raise (full) ▪ Rock slope protection ▪ Jet grouting ▪ Seepage berm ▪ Closure ▪ Setback levee	▪ Flood wall ▪ Slurry cutoff wall ▪ Relief wells ▪ Interior drain ▪ Slope flattening ▪ Sheet pile wall ▪ Stability berm
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

Although different flood and recreation alternatives are proposed for the reaches, Effect PUB-2 could occur in all the program reaches: Sacramento River North, Sacramento River South, Port North, Port South, South Cross, DWSC East and West, Sacramento Bypass, and Yolo Bypass Levee reaches.

Effect PUB-2 Finding	With Mitigation
Less than significant	N/A

Effect PUB-3: Expansion of Stormwater Drainage Facilities

The operation of the proposed relief wells could result in new flows that may require expansion of stormwater drainage facilities or require the construction of new drainage facilities. However, in most cases, it is likely that the existing storm drain infrastructure has adequate capacity to carry the small amount of additional discharge from the relief well collection systems. During maximum flows, it is anticipated that the relief well system would generate approximately 70 gallons of water per minute. For most normal operations, the flow would be much less than 70 gallons per minute. If required at all, any expansion of drainage facilities would be limited to the specific area where relief wells are constructed and would not be substantial. Therefore, this effect is less than significant. No mitigation is required.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause Effect PUB-3:

Program	Alternative	
Flood	▪ Relief wells	▪ Slurry cutoff wall

Affected Reaches

Although different flood and recreation alternatives are proposed for the reaches, Effect PUB-3 could occur in the program reaches where relief wells are proposed: Sacramento River South, Port South, and DWSC East Levee reaches.

Effect PUB-3 Finding	With Mitigation
Less than significant	N/A

Section 3.17

Public Health and Environmental Hazards

3.17.1 Introduction

This section describes the regulatory and environmental setting for public health and environmental hazards, including hazardous materials, emergency response and evacuation plans, the potential for wildland fires, and health hazards to the public in the city of West Sacramento. The effects on public health and environmental hazards that would result from the program are described, as well as mitigation measures that would reduce significant effects.

The key sources of data and information used in the preparation of this section are listed below.

- *Draft 2030 Countywide General Plan* for Yolo County (Yolo County 2008)
- *West Sacramento General Plan Policy Document* (City of West Sacramento 1990)
- *Solano County General Plan* (Solano County 2008)

3.17.2 Affected Environment

3.17.2.1 Regulatory Setting

3.17.2.1.1 Federal

The principal Federal regulatory agency responsible for the safe use and handling of hazardous materials is the EPA. Two key Federal regulations pertaining to hazardous wastes are described below. Other applicable Federal regulations are contained primarily in CFR Titles 29, 40, and 49.

Resource Conservation and Recovery Act

The Federal Resource Conservation and Recovery Act enables EPA to administer a regulatory program that extends from the manufacture of hazardous materials to their disposal, thus regulating the generation, transportation, treatment, storage, and disposal of hazardous waste at all facilities and sites in the nation.

Comprehensive Environmental Response, Compensation, and Liability Act

The Comprehensive Environmental Response, Compensation, and Liability Act (also known as Superfund) was passed to facilitate the cleanup of the nation's toxic waste sites. In 1986, the act was amended by the Superfund Amendment and Reauthorization Act Title III (community right-to-know laws). Title III states that past and present owners of land contaminated with hazardous substances can be held liable for the entire cost of the cleanup, even if the material was dumped illegally when the property was under different ownership.

3.17.2.1.2 State

California regulations are equal to or more stringent than Federal regulations. EPA has granted the State of California primary oversight responsibility to administer and enforce hazardous waste management programs. State regulations require planning and management to ensure that hazardous wastes are handled, stored, and disposed of properly to reduce risks to human and environmental health. Several key laws pertaining to hazardous wastes, emergency services, and mosquito abatement are discussed below.

Hazardous Materials Release Response Plans and Inventory Act of 1985

The Hazardous Materials Release Response Plans and Inventory Act, also known as the Business Plan Act, requires businesses using hazardous materials to prepare a plan that describes their facilities, inventories, emergency response plans, and training programs. Hazardous materials are defined as unsafe raw or unused material that is part of a process or manufacturing step. They are not considered hazardous waste. Health concerns pertaining to the release of hazardous materials, however, are similar to those relating to hazardous waste.

Hazardous Waste Control Act

The Hazardous Waste Control Act created the state hazardous waste management program, which is similar to but more stringent than the Federal Resource Conservation and Recovery Act program. The act is implemented by regulations contained in Title 26 CCR, which describes the following elements required for the proper management of hazardous waste:

- identification and classification;
- generation and transportation;
- design and permitting of recycling, treatment, storage, and disposal facilities;
- treatment standards;
- operation of facilities and staff training; and
- closure of facilities and liability requirements.

These regulations list more than 800 materials that may be hazardous and establish criteria for identifying, packaging, and disposing of such waste. Under the Hazardous Waste Control Act and Title 26, the generator of hazardous waste must complete a manifest that accompanies the waste from generator to transporter to the ultimate disposal location. Copies of the manifest must be filed with the California Department of Toxic Substances and Control.

Emergency Services Act

Under the Emergency Services Act, the state developed an emergency response plan to coordinate emergency services provided by Federal, state, and local agencies. Rapid response to incidents involving hazardous materials or hazardous waste is an important part of the plan, which is administered by the California Office of Emergency Services. The office coordinates the responses of other agencies, including EPA, the California Highway Patrol, RWQCBs, air quality management districts, and county disaster response offices.

3.17.2.1.3 Local

Yolo County

The Health and Safety Element of the *Draft 2030 Countywide General Plan* for Yolo County (Yolo County 2008) contains goals, policies, and actions aimed at reducing the risk associated with natural and human-made hazards within the county. Any violation of these goals, policies, and actions would constitute a significant effect.

Goals

GOAL HS-2: Flood Hazards. Protect the public and reduce damage to property from flood hazards.

Policies

Policy HS-2.2: Ensure and enhance the maintenance and integrity of flood control levees.

Policy HS-2.3: Actively update and maintain policies and programs to ensure consistency with state and Federal requirements.

Actions

Action HS-A4: Require a minimum of 100-year flood protection for new construction, and strive to achieve 200-year flood protection for unincorporated communities where such levels of protection are not provided, require new development to adhere to the requirements of state law and the County Flood Damage Prevention Ordinance.

Action HS-A13: Require a minimum 50-foot setback for all permanent improvements from the toe of any flood control levee.

Action HS-A15: Support the efforts of levee maintenance districts with efforts to secure state and federal funding for geotechnical studies of levees and implementation of associated improvements.

Action HS-A16: Encourage flood hazard reduction projects along the Sacramento River to be consistent with the guidelines of the Sacramento River Corridor Floodway Management Plan.

Action HS-A17: Coordinate with local, state and federal agencies to define existing and potential flood problem areas, including the possible effects associated with global climate change, and to maintain and improve levees and other flood control features.

Action HS-A18: Develop a detailed maintenance and funding plan for levees under County control, to ensure that levee safety is maintained.

Action HS-A19: Support and encourage responsible agencies to site new levees or major rehabilitation of levees at a distance from the river and from existing levees, where feasible. This would provide a degree of redundancy in the system, increase the land available for habitat and flood storage, reduce operation and maintenance costs, and help to ensure the integrity of the structures.

Action HS-A21: Ensure that the upgrade, expansion, or construction of any flood control levee demonstrates that it will not adversely divert flood water or increase flooding.

Action HS-A23: Improve the county's classification within the Federal Emergency Management Agency Community Rating System.

Action HS-A28: Pursuant to Section 8201 of the State Water Code, develop local plans for flood protection, including analysis of financing options to construct and maintain any needed improvements, to address how 100-year floodplain protection for each community may be provided. Those communities that are economically disadvantaged shall have priority in developing flood protection plans. The cities shall be consulted in development of the plans, which shall be consistent with the Central Valley Flood Protection Plan.

Solano County

The Public Health and Safety Chapter of the *Solano County General Plan* (Solano County 2008) contains goals, policies, and implementation programs aimed at reducing the risks associated with natural and human-made hazards within the County. Any violation of these goals, policies, and implementation programs would constitute a significant effect.

Goals

HS.G-1: Minimize the potential for loss of life and property resulting from natural or human-caused hazards.

HS.G-5: Recognize the multiple functions of the natural environment for safety, recreation, protection from climate changes, and economic uses.

Policies

HS.P-2: Restore and maintain the natural functions of riparian corridors and water channels throughout the county to reduce flooding, convey stormwater flows, and improve water quality.

HS.P-6: Work with federal, state, and local agencies to improve flood control and drainage throughout the county.

HS.P-8: Work with responsible parties to ensure dams, levees, and canals throughout the county are properly maintained and/or improved.

HS.P-10: Ensure that flood management policies that minimize loss of life and property also balance with environmental health considerations of the floodplain and therefore do not cause further erosion, sedimentation, or water quality problems in the floodplain area.

Implementation Programs

HS.I-5: Require periodic stream maintenance by private property owners, and undertake regular stream maintenance by the appropriate public agencies.

HS.I-6: Continue to make regular flood control and drainage improvements as recommended by local agency plans, the U.S. Army Corps of Engineers, and the California Reclamation Board. These actions are independent of and in addition to the development review process.

HS.I-7: During project review, require the use of stormwater management techniques in developed upstream watershed areas that protect low-lying areas from flooding. Incorporate appropriate measures into the development review process to mitigate flooding and prevent erosion in and around county ditches.

HS.I-10: During project review, encourage the use of landscaping practices and plants that will reduce demand on water, retain runoff, decrease flooding, and recharge groundwater.

HS.I-13: Work with the Solano County Water Agency to create a countywide comprehensive flood management plan.

HS.I-15: Work with the Solano County Water Agency (or successor agency) in preparing a hydrological analysis of uplands, identifying the different watersheds that drain into the county, establishing flood-related objectives and priorities on a study area basis, and translating those into a coordinated series of flood-preventive measures for each watershed.

City of West Sacramento General Plan

The Central Valley Flood Protection Plan requires 200-year flood protection by the year 2025. The time and effort required to fully evaluate approximately 50 miles of levees, develop recommended strategies for improvement, and implement those improvements prompted action without further delay. In addition, within its General Plan, the City adopted a goal of achieving 200-year flood protection. The Health and Safety Section of the *City of West Sacramento General Plan Policy Document* (City of West Sacramento 1990) contains goals and policies aimed at reducing the risks associated with natural and human-made hazards within the county. Any violation of these goals and policies would constitute a significant effect.

Goal A: To prevent loss of life, injury, and property damage due to geologic and seismic hazards.

Policy 1: The City shall require preparation of geotechnical reports and impose appropriate mitigation measures to ensure, within the limits of technical and economic feasibility, that new structures are able to withstand the effects of seismic activity, including liquefaction.

Policy 3: The City shall request that responsible agencies regularly inspect and repair area levees, as needed, to ensure structural integrity in the event of seismic activity.

Goal B: To prevent loss of life, injury, and property damage due to flooding.

Policy 8: The City shall cooperate with area reclamation districts and other responsible agencies in the maintenance and improvement of levees and drainage channels.

Policy 9: The City shall support state and federal legislation which provides funding for the construction of flood control improvements in urbanized areas.

Policy 10: the City shall discourage uses that promote the erosion or structural deterioration of levees.

Goal C: To prevent loss of life, injury, and property damage due to wildland, cropland, and structural fires, explosions and release of hazardous materials.

Goal D: To ensure that City emergency response procedures are adequate in the event of natural or man-made disasters.

West Sacramento Area Flood Control Agency

WSAFCA is proposing the program to improve the levees in Yolo and Solano Counties that protect the city of West Sacramento. WSAFCA is a Joint Powers Authority created in 1994 through a Joint Exercise of Powers Agreement by the City, RD 900, and RD 537. WSAFCA was established to coordinate the planning and construction of flood protection facilities and to finance the local share of flood control projects. WSAFCA is responsible for the operations and maintenance of the detention basins, pump stations, and levees that protect the city.

3.17.2.2 Environmental Setting

3.17.2.2.1 Hazardous Materials

Hazardous materials are chemicals and other substances defined as hazardous by Federal and state laws and regulations. In general, these materials are substances that, because of their quantity, concentration, or physical, chemical, or infectious characteristics, may have harmful effects on public health or the environment during their use or when released to the environment. Hazardous materials also include waste chemicals and spilled materials.

The program levee reaches are located in urban, suburban, and rural areas. Potential sources of hazardous materials and waste may exist in the urbanized as well as agricultural areas adjacent to the levees. Hazardous materials may be present in the program area in a variety of common contexts, including:

- pesticides, herbicides, and fertilizers;
- petroleum hydrocarbons;
- underground storage tanks;
- contaminated debris;
- lead;
- wastewater;
- pits or ponds;
- stormwater runoff structures; and
- transformers that may contain polychlorinated biphenyls (PCBs).

Two sites in the study area, both along the Sacramento River North Levee, have known occurrences of hazardous materials. One of the sites is the petroleum groundwater plume located at the DWR Maintenance Yard and the Rivers site, which is described in more detail in Section 3.3, Water Quality and Groundwater Resources. Hazardous materials have been identified and recorded in an area called the Artist Colony, located on the waterside of the northern portion of the Sacramento River North Levee. The Artist Colony houses artist studios and industrial equipment. Future project sites would have Phase 1 evaluations performed prior to geotechnical site analysis to determine the presences of hazardous materials.

3.17.2.2.2 Wildland Fires

There are areas of undeveloped land in the city of West Sacramento and along the DWSC that may be more susceptible to wildland fire. These areas are composed of annual grasses that become dry during the summer month, which raises the risk of grassland fire. Levee reaches that comprise these fire-prone areas are the Sacramento River South, Port South, DWSC West, DWSC East, and South Cross Levees.

3.17.2.2.3 Emergency Response and Evacuation

Emergency response and evacuation services for the program area are provided by the various departments in the city of West Sacramento and cities nearest to the program area and through Yolo

County and Solano County Sheriff, Fire, and Emergency Services Departments. The city of West Sacramento, RD 537, and RD 900 have entered a joint flood operation agreement. The agreement has established procedures to protect the health, safety, welfare and property of the residents and landowners in the program area. Procedures described in the document consist of flood preparedness, information management, monitoring, flood fighting, and flood evacuation.

3.17.3 Environmental Consequences

This section describes the public health and environmental hazard effects associated with the proposed program. It describes the methods used to determine the effects of the program and lists the thresholds used to conclude whether an effect would be significant. Measures to mitigate (i.e., avoid, minimize, rectify, reduce, eliminate, or compensate for) significant effects accompany each effect discussion.

3.17.3.1 Assessment Methods

The evaluation of potential effects on public health and environmental hazards addresses the potential for health and safety hazards during construction of the levee alternatives. The analysis includes evaluation of (1) the potential effects related to construction activities on workers, and (2) general safety of and hazards to both workers and the public posed by the construction and implementation of levee alternatives.

3.17.3.2 Determination of Effects

Criteria used for determining the significance of an effect on public health and environmental hazards are based on the environmental checklist included in Appendix G (14 CCR 15000 *et seq*.) of the State CEQA Guidelines as well as professional standards and practices. The proposed project was considered to cause a significant effect if it would:

- create a significant hazard to the public or the environment through the routine transport, use, or disposal of hazardous materials;
- create a significant hazard to the public or the environment through reasonably foreseeable upset and accident conditions involving the release of hazardous materials to the environment;
- emit hazardous emissions or involve handling hazardous or acutely hazardous materials, substances, or waste within 0.25 mile of an existing or proposed school;
- be located on a site that is on a list of hazardous materials sites compiled pursuant to California Government Code 65962.5, and as a result would create a significant hazard to the public or the environment;
- impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan;
- place within a 100-year flood hazard area structures that would impede or redirect flood flows;
- expose people or structures to a significant risk of loss, injury, or death involving flooding, including flooding as a result of the failure of a levee or dam; or
- significantly affect drinking water quality.

3.17.3.3 Effects and Mitigation Measures

3.17.3.3.1 No Action Alternative

To recap from Chapter 2, Alternatives, the No Action Alternative is the continuation of the existing deficiencies along the nine levee reaches and absence of levee alternatives to increase the level of protection. Current levee operations and maintenance activities would continue. No potential construction-related effects would occur, such as accidental spill or discovery of hazardous materials related to this program.

However, without improvements to the West Sacramento levee system, the risk of levee failure would remain high. A levee failure in the city's levee system could result in flooding that could upset stored hazardous materials and spread agricultural pesticides, oil, gasoline, and other hazardous materials in flood waters, creating hazardous conditions for the public and the environment. Flood damage to homes and other structures can render them dangerous as a result of structural damage and contamination. Electrical systems could be damaged by flooding, posing the potential of fires, and natural gas leaks could result poisoning through inhalation of fumes, or could cause a sudden explosion if sparked. The likelihood of a significant amount of mold production is high after a flood event. Mold not only threatens the physical integrity of structures, but also poses its own health risks. Mold can cause lung infections, skin irritations, and other health dangers, especially for those with asthma, allergies, or suppressed immune systems. Additionally, the floodwaters themselves and ponds left behind could provide a wide breeding ground for mosquitoes, and the incidence of West Nile Virus and other diseases would likely increase.

Effects on the water supply system could be particularly severe in a flood event, as a single break in a water delivery pipe or main could contaminate the entire city's water supply. All breaks and leaks would need to be repaired and the pipes of every house would need to be flushed to remove contamination before residents and businesses could rely on safe water. Depending on the severity and location of the flooding and contamination, this effort could take a significant amount of time.

Varying levels of damage could be done to public service structures as well, causing delays in fire protection, police protection, or emergency medical assistance. A major flood event could also stress the region's emergency response and hospital services, as the likelihood of injury resulting from the flood event is high, and evacuees may not have access to their regular medications.

However, the potential for such an occurrence is uncertain, and the magnitude and duration of any related risks cannot be predicted. Because the effects of a levee failure are unpredictable, a precise determination of significance is not possible and cannot be made.

3.17.3.3.2 Flood and Recreation Program Alternatives

Effect PH-1: Incidental Release of Hazardous Materials during Construction

Program implementation would require the use of hazardous materials such as fuels and lubricants to operate construction equipment and vehicles such as excavators, compactors, haul trucks, and loaders. Bentonite (a non-hazardous material) would be transported to sites where slurry cutoff wall construction would occur. Construction contractors would be required to use, store, and transport hazardous materials in compliance with Federal, state, and local regulations during project construction. However, fuels, and lubricants could be accidentally released into the environment at the construction site and along haul routes, causing environmental or human

exposure to these hazards. Risks to water quality (surface, ground, and drinking water) associated with incidental release of these materials are addressed in Section 3.3, Water Quality and Groundwater Resources.

As discussed in Section 3.3, the implementation of environmental commitments, including a SWPPP, a bentonite slurry spill contingency plan (BSSCP), an SPCCP, and the implementation of Mitigation Measures WQ-MM-1 and WQ-MM-2, would ensure that the risk of accidental spills and releases into the environment would be minimal and that the effect on water quality would be less than significant.

In addition, WSAFCA would be required to comply with applicable Federal, state, and local laws, which would reduce the potential for accidental release of hazardous materials during their transport and use. Consequently, the risk of incidental release of hazardous materials during their transport and use in program construction activities is low and the effect is considered less than significant.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause Effect PH-1:

Program	Alternative	
Flood	▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Rock slope protection ▪ Jet grouting ▪ Seepage berm ▪ Closure ▪ Setback levee	▪ Flood wall ▪ Slurry cutoff wall ▪ Relief wells ▪ Interior drain ▪ Slope flattening ▪ Sheet pile wall ▪ Stability berm
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

Although different flood program alternatives are proposed for the reaches, Effect PH-1 could occur in all the program reaches: Sacramento River North, Sacramento River South, Port North, Port South, South Cross, DWSC East and West, Sacramento Bypass, and Yolo Bypass Levee reaches.

Effect PH-1 Finding	With Mitigation
Less than significant	N/A

Effect PH-2: Exposure to Hazardous Materials Encountered at Project Sites

There is the potential that known or previously undocumented hazardous materials could be encountered at project sites. Excavation and construction activities at or near areas of currently unrecorded soil or groundwater contamination could result in the exposure of construction workers, the general public, and the environment to hazardous materials such as petroleum

hydrocarbons, pesticides, herbicides, fertilizers, contaminated debris, or elevated levels of other chemicals that could be hazardous. There are two known sites within the program area that contain hazardous materials: the Artist Colony and the petroleum groundwater plume at the DWR Maintenance Yard, described in the Environmental Setting. Construction activities in the vicinity of known or potentially unknown recognized environmental concerns could result in public health hazards.

In addition, program activities include the construction of setback levees, which may occur in areas that were previously used for agricultural purposes. The inclusion of these areas in the Sacramento River floodway could, during periodic flood events, result in the release of different types of contaminants that exist in the soil into river water, significantly affecting water quality. These contaminants include pesticides, fertilizers, organic litter, and debris containing hazardous substances. Exposure to these substances would result in a significant effect to public health and the environment.

Implementation of Mitigation Measures PH-MM-1, WQ-MM-1, and WQ-MM-2 described in Section 3.3, Water Quality and Groundwater Resources, and the implementation of environmental commitments of a SWPPP, a BSSCP, and SPCCP, as described in Section 2.9 of Chapter 2, Alternatives, would ensure that the effect on public health and the environment would be less than significant.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause Effect PH-2:

Program	Alternative	
Flood	▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Rock slope protection ▪ Jet grouting ▪ Seepage berm ▪ Closure ▪ Setback levee	▪ Flood wall ▪ Slurry cutoff wall ▪ Relief wells ▪ Interior drain ▪ Slope flattening ▪ Sheet pile wall ▪ Stability berm
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

Although different flood program alternatives are proposed for the reaches, Effect PH-1 could occur in all the program reaches: Sacramento River North, Sacramento River South, Port North, Port South, South Cross, DWSC East and West, Sacramento Bypass, and Yolo Bypass Levee reaches.

Effect PH-2 Finding	With Mitigation
Significant	Less than significant

Mitigation

Mitigation Measure WQ-MM-1 Implement Measures to Maintain Surface Water Quality and Groundwater Quality

Mitigation Measure WQ-MM-2: Implement Provisions for Dewatering

Mitigation Measure PH-MM-1: Complete Phase I and Phase II (if necessary) Environmental Site Assessment Investigations and Implement Required Measures

WSAFCA will conduct Phase I ESAs and, if necessary, Phase II ESAs or other appropriate testing. If necessary, the assessment will include an analysis of soil or groundwater samples for the potential contamination sites that have not yet been covered by previous investigations before construction activities begin.

Recommendations in Phase I and Phase II ESAs to address any contamination that is found will be implemented before initiating ground-disturbing activities. In addition, WSAFCA will implement the following measures before ground-disturbing or demolition activities begin, in order to reduce health hazards associated with potential exposure to hazardous substances:

- Prepare a site plan that identifies any necessary remediation activities appropriate for proposed land uses, including excavation and removal of contaminated soils, and redistribution of clean fill material on the project site. The plan will include measures that ensure the safe transport, use, and disposal of contaminated soil and building debris removed from the site, as well as any other hazardous materials. In the event that contaminated groundwater is encountered during site excavation activities, the contractor will report the contamination to the appropriate regulatory agencies, dewater the excavated area, and treat the contaminated groundwater to remove contaminants before discharge into the sanitary sewer system. The contractor will be required to comply with the plan and applicable Federal, state, and local laws.
- Retain licensed contractors to remove all underground storage tanks.
- Notify the appropriate Federal, state, and local agencies if evidence of previously undiscovered soil or groundwater contamination is encountered during construction activities. Any contaminated areas will be cleaned up in accordance with the recommendations of Yolo County Environmental Health Division, Central Valley RWQCB, California Department of Toxic Substances Control, or other appropriate Federal, state or local regulatory agencies.,
- Prepare a worker health and safety plan before the start of construction activities that indentifies, at a minimum, all contaminants that could be encountered during construction activity; all appropriate worker, public health, and environmental protection equipment and procedures to be used during project activities; emergency response procedures; the most direct route to the nearest hospitals; and a Site Safety Officer. The plan will describe actions to be taken should hazardous materials be encountered on site, including protocols for handling hazardous materials and preventing their spread, and emergency procedures to be taken in the event of a spill.

Effect PH-3: Safety Hazards from the Construction Site and Vehicles

Under the proposed program, construction workers would operate vehicles and other mechanical equipment that, if used improperly, could result in safety hazards at the construction site. WSAFCA would ensure that all workers are properly trained to operate equipment. Safety precautions would

be followed at all times during construction to avoid accidents. WSAFCA also would require that all workers have a valid driver's license and insurance. These measures would ensure that this effect would be less than significant.

In addition, people may walk, ride bicycles, or otherwise use the levee during the construction period. The staging of the equipment when construction is not underway (i.e., weekends, holidays, and overnight) may pose a threat to public safety if the equipment is not properly secured. Proper signage and detours would be provided as stated in the environmental commitment to provide notification of construction area closure (described in Section 2.9, Chapter 2, Alternatives). These measures would reduce the risk to the public when construction is underway and when it is not. Therefore, this effect would be less than significant. No mitigation is required.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause Effect PH-3:

Program	Alternative	
Flood	▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Rock slope protection ▪ Jet grouting ▪ Seepage berm ▪ Closure ▪ Setback levee	▪ Flood wall ▪ Slurry cutoff wall ▪ Relief wells ▪ Interior drain ▪ Slope flattening ▪ Sheet pile wall ▪ Stability berm
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

Although different flood program alternatives are proposed for the reaches, Effect PH-3 could occur in all the program reaches: Sacramento River North, Sacramento River South, Port North, Port South, South Cross, DWSC East and West, Sacramento Bypass, and Yolo Bypass Levee reach.

Effect PH-3 Finding	With Mitigation
Less than significant	N/A

Effect PH-4: Protection of People or Structures from Flood Hazards

All levees have the potential to fail, regardless of design. USACE has set forth guidelines for levee design. The levees along the Sacramento River, DWSC, Yolo Bypass, and the Port of Sacramento would be improved using methods that meet engineering requirements set forth by both USACE and the Reclamation Board. In addition, these levees would be improved to meet FEMA 200-year flood protection certification. This would be an improvement compared to the existing flood protection. Therefore, this effect would be beneficial.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause Effect PH-4:

Program	Alternative	
Flood	▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Rock slope protection ▪ Jet grouting ▪ Seepage berm ▪ Closure ▪ Setback levee	▪ Flood wall ▪ Slurry cutoff wall ▪ Relief wells ▪ Interior drain ▪ Slope flattening ▪ Sheet pile wall ▪ Stability berm
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

Although different flood program alternatives are proposed for the reaches, Effect PH-4 could occur in all the program reaches: Sacramento River North, Sacramento River South, Port North, Port South, South Cross, DWSC East and West, Sacramento Bypass, and Yolo Bypass Levee reach.

Effect PH-4 Finding	With Mitigation
Beneficial	N/A

Effect PH-5: Hazardous Materials, Substances, or Waste Handled or Emitted within 0.25 Mile of an Existing or Proposed School

There are a total of four schools located within 0.25 mile of the program area. These schools include Bryte Elementary School located at 637 Todhunter Avenue, Riverbank Elementary School located at 1100 Carrie Street, University of California Santa Barbara Children's Center located at 574 C Street, and Discovery Preschool located at 205 Stone Boulevard. Construction of the program would involve the use of potentially hazardous materials, such as fuels (gasoline and diesel), oils and Undocumented contaminated soil or water may be found during construction. The effect of exposure to incidentals release of these hazardous materials by school-aged children would be significant.

WSAFCA would be required to comply with applicable Federal, state, and local laws related to transport and use of hazardous materials. Consequently, the risk of incidental release of hazardous materials near existing or proposed schools during their transport and use during program construction activities would be low. These measures, along with the implementation of Mitigation Measures PH-MM-1 and PH-MM-2 would ensure that this effect is less than significant.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause Effect PH-5:

Program	Alternative	
Flood	▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Rock slope protection ▪ Jet grouting ▪ Seepage berm ▪ Closure ▪ Setback levee	▪ Flood wall ▪ Slurry cutoff wall ▪ Relief wells ▪ Interior drain ▪ Slope flattening ▪ Sheet pile wall ▪ Stability berm
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

Although different flood program alternatives are proposed for the reaches, it is assumed that Effect PH-5 could occur in all the program reaches. While all program reaches are not within 0.25 mile of a school, the program implementation will occur over an approximate 15 year period and additional schools may be built within that timeframe.

Effect PH-5 Finding	With Mitigation
Significant	Less than significant

Mitigation

Mitigation Measure PH-MM-2: Notify Washington Unified School District and Applicable Schools Located within 0.25 Mile of Project Construction Activities

WSAFCA will provide written notification of projects to each of the affected schools and the Washington Unified School District within 30 days prior to certification of the EIS/EIR and will consult with Washington Unified School District regarding potential effects on school children from hazards associated with project construction.

Section 3.18
Cultural Resources

3.18.1 Introduction

This section describes the regulatory and environmental setting for cultural resources; the effects on cultural resources that would result from the program; and mitigation measures that would reduce these effects. This section also discusses the prehistoric and historic background to better define the context of the cultural resources associated with the proposed study area.

The term *cultural resources* encompasses several types of resources, including archaeological, architectural, and traditional cultural properties (TCPs). Archaeological sites include both prehistoric and historic deposits, as well as submerged resources. Architectural properties are buildings, bridges, and infrastructure. TCPs are those locations of importance to a particular group. TCPs are frequently important to Native American groups because of the function the location serves in traditional ceremonies or other activities such as plant gathering. Cultural resources also include cultural landscapes, defined by McClelland et al. (1995:3) as "a geographic area that historically has been used by people, or shaped and modified by human activity, occupancy, or intervention, and that possesses a significant concentration, linkage, or continuity of areas of land use, vegetation, buildings and structures, roads and waterways, and natural features."

3.18.2 Affected Environment

3.18.2.1 Regulatory Setting

3.18.2.1.1 Federal

Section 106 of the National Historic Preservation Act

The proposed program would require a permit from USACE. The permitting Federal agency is required to comply with Section 106 of the National Historic Preservation Act (NHPA) of 1966, as amended, and its implementing regulations (36 CFR 800). Section 106 of the NHPA requires that, before beginning any undertaking, a Federal agency must take into account the effects of the undertaking on *historic properties* (cultural resources eligible for listing on the National Register of Historic Places [NRHP]) and afford the Advisory Council on Historic Preservation (ACHP) an opportunity to comment on these actions. The Section 106 process has five basic steps.

1. Initiate the Section 106 process, including the identification of consulting parties, such as Native American tribes.
2. Identify and evaluate cultural resources to determine whether they are historic properties.
3. Assess the effects of the undertaking on historic properties within the area of potential effect (APE).

4. If historic properties may be subject to an adverse effect, the Federal agency, the State Historic Preservation Officer (SHPO), and any other consulting parties (including Native American tribes and the ACHP) continue consultation to seek ways to avoid, minimize, or mitigate the adverse effect. A memorandum of agreement (MOA) is usually developed to document the measures agreed upon to resolve adverse effects. Alternatively, the Federal agency may prepare and execute a Programmatic Agreement (PA) with the aforementioned parties to comply with 36 CFR 800, particularly in the context of complex undertakings that entail years of implementation actions or where the undertaking's effects on historic properties cannot be well characterized during the planning phase.
5. Proceed in accordance with the terms of the MOA or PA.

Specific regulations regarding compliance with Section 106 state that, although the tasks necessary to comply with Section 106 may be delegated to others, the Federal agency (in this case, USACE) is ultimately responsible for ensuring that the Section 106 process is completed according to statute.

Federal Historic Significance Criteria

For Federal projects, cultural resource significance is evaluated in terms of eligibility for listing in the NRHP. NRHP criteria for eligibility are defined below. To be considered eligible for listing in the NRHP, a property need only meet one, not all, of the significance criteria outlined below.

The quality of significance in American history, architecture, archaeology, and culture is present in districts, sites, buildings, structures, and objects of state and local importance that possess integrity of location, design, setting, materials, workmanship, feeling and association, and that:

A. are associated with events that have made a contribution to the broad pattern of our history;
B. are associated with the lives of people significant in our past;
C. embody the distinct characteristics of a type, period, or method of construction, or that represent the work of a master, or that possess high artistic values, or that represent a significant and distinguishable entity whose components may lack individual distinction; or
D. have yielded, or are likely to yield, information important in prehistory or history (36 CFR 60.4).

3.18.2.1.2 State

CEQA requires that public agencies that finance or approve public or private projects must assess the effects of the project on cultural resources. CEQA requires that, if a project results in significant effects on important cultural resources, alternative plans or mitigation measures must be considered; only significant cultural resources, however, need to be addressed.

Therefore, before the level of significance of effects can be determined and appropriate mitigation measures developed, the significance of cultural resources must be determined. The following steps are normally taken in a cultural resources investigation to comply with CEQA:

1. Identify cultural resources.
2. Evaluate the significance of the cultural resources based on established thresholds of significance.
3. Evaluate the effects of a project on all cultural resources.

4. Develop and implement measures to mitigate the effects of the project on significant cultural resources.

Because the program is located on non-Federal land in California, it must comply with state laws pertaining to the inadvertent discovery of human remains of Native American origin. The procedures that must be followed if burials of Native American origin are discovered on non-Federal land in California are described in the Effects and Mitigation Measures section, below.

State Historic Significance Criteria

For a historical resource to be eligible for listing in the California Register of Historic Resources (CRHR), it must be significant at the local, state, or national level under one or more of the following criteria from 14 CCR 15064.5(a)(3)(A–D).

1. It is associated with events that have made a significant contribution to the broad patterns of California's history and cultural heritage.
2. It is associated with the lives of persons important in our past.
3. It embodies the distinctive characteristics of a type, period, region, or method of construction, or represents the work of an important creative individual or possesses high artistic values.
4. It has yielded, or may be likely to yield, information important in prehistory or history.

Historical resources automatically listed in the CRHR include those historic properties listed in, or formally determined to be eligible for listing in, the NRHP (PRC 5024.1).

In addition, CEQA distinguishes between two classes of archaeological resources: archaeological sites that meet the definition of a historical resource as defined above and "unique archaeological resources." An archaeological resource is considered unique if it:

- is associated with an event or person of recognized significance in California or American history or of recognized scientific importance in prehistory;
- can provide information that is of demonstrable public interest and is useful in addressing scientifically consequential and reasonable research questions; or
- has a special or particular quality such as oldest, best example, largest, or last surviving example of its kind (PRC 21083.2).

Resources that qualify as unique archaeological resources also meet at least one of the CRHR criteria. It is current professional practice, therefore, to address the importance or significance of cultural resources by determining solely if it is eligible for listing in the CRHR, without the expressed distinction or determination as to its status as a unique archaeological resource. For the purposes of this program, significant cultural resources as defined by CEQA are defined as those resources that meet at least one of the CRHR eligibility criteria.

3.18.2.1.3 Local

Yolo County General Plan

Yolo County strives to encourage the enhancement of cultural quality and education in Yolo County through the development of goals, objectives, and policies that the county has established in the

Historic Preservation Element of the *Yolo County General Plan*, Part 1 (adopted July 1983) to preserve County history and historical sites.

HP 1—Goal: Yolo County shall support the preservation and enhancement of historic and prehistoric resources within the County when fiscally able.

HP 2—Objectives:

2.1: To preserve Yolo County's natural resources with historical significance by designating certain natural resources such as trees and vegetation as "historic" and by supporting a program to preserve them.

2.2: To preserve Yolo County's prehistoric resources by identifying and preserving Native American sites and other significant archaeological sites and by encouraging development of demonstration sites.

Yolo County adopted the following actions as means for helping achieve its goal and objectives:

- Identification of historic resources within the County;
- Recording the historic resources identified in the 1986 Yolo County Historic Resources Survey on the general plan map and maintenance and updating of the map for planning purposes;
- Adoption of a Historic Preservation Ordinance and the establishment of a Yolo County Historic Preservation Commission;
- Support for the conversion of older residential structures in commercial zones to commercial or office use and of older historically significant structures in agricultural areas to tourist uses through the use permit process while maintaining or enhancing their historical authenticity;
- Encouragement of County efforts to seek financing for the preservation of the County's historic resources;
- To encourage the property owners to revitalize their properties through incentives such as utilizing the Historic Building Code, easements, state and Federal tax exemptions as well as seeking Community Development Block Grant funds.

2.4: To promote museums to preserve the prehistorical, historical and agricultural heritage of Yolo County by the following actions:

- Continued support for the Yolo County Historic Museum;
- Promotion of museums within historic structures;
- Support for establishment of additional museums in the County.

2.5: To preserve the historical records of Yolo County and make them accessible to the public by maintaining the Yolo County Archives.

Solano County General Plan

Solano County Board of Supervisors conditionally adopted the new *Solano County General Plan* in August 2008. Solano County voters approved Measure T on the November 4, 2008 ballot and confirmed the Board of Supervisors' approval of the general plan. Chapter 4 of the new general plan addresses resources, including "substantial historic and prehistoric sites." Its purpose is to identify the goals and policies Solano County will implement in its daily decision-making process to protect

such resources. The following goals and policies, as stated in the *Solano County General Plan* on the county's website, pertain to cultural resources:

RS.G-1: Manage and preserve the diverse land, water, and air resources of the county for the use and enrichment of the lives of present and future generations.

RS.G-4: Preserve, conserve, and enhance valuable open space lands that provide wildlife habitat; conserve natural and visual resources; convey cultural identity; and improve public safety.

RS.P-38: Identify and preserve important prehistoric and historic structures, features, and communities.

RS.P-39: Tie historic preservation efforts to the County's economic development pursuits, particularly those relating to tourism.

RS.P-40: Consult with Native American governments to identify and consider Native American cultural places in land use planning.

Additionally, the new general plan provides implementation programs that identify specific action plans to achieve the goals and policies discussed above.

RS.I-25: Require cultural resources inventories of all new development projects in areas identified with medium or high potential for archeological or cultural resources. Where a preliminary site survey finds medium to high potential for substantial archaeological remains, the County shall require a mitigation plan to protect the resource before issuance of permits. Mitigation may include:

- Having a qualified archaeologist present during initial grading or trenching (monitoring);
- Redesign of the project to avoid archaeological resources (this is considered the strongest tool for preserving archaeological resources);
- Capping the site with a layer of fill; and/or
- Excavation and removal of the archaeological resources and curation in an appropriate facility under the direction of a qualified archaeologist.
- Alert applicants for permits within early settlement areas to the potential sensitivity if significant archaeological resources are discovered during construction or grading activities, such activities shall cease in the immediate area of the find until a qualified archaeologist can determine the significance of the resource and recommend alternative mitigation.

RS.1-26: Work with federal and state agencies to identify, evaluate and protect the county's important historic and prehistoric resources. Programs administered by such agencies may include:

- California Historical Landmarks, California Points of Historical Interest, California Register of Historic Resources, National Register of Historic Places, State Historic Building Code

RS.1-27: Refer to the state Senate Bill 18 guidelines and requirements regarding cultural resources. Programs the County will engage in may include:

- ensuring local and Native American governments are provided with information early in the planning process,
- working with Native American governments to preserve and protect Native American cultural sites by designating them as open space where possible,

- providing management and treatment plans to preserve cultural places, and working with Native American groups to manage their cultural places.

RS.1-38: Protect and promote the county's historic and prehistoric resources by:

- providing educational programs to the public, staff, and commissions that promote awareness of the county's history and the value in preserving historic or prehistoric resources; and
- exploring and developing historic or prehistoric sites that can be used appropriately as visitor-oriented destinations.

RS.1-29: Develop historic preservation programs and development guidelines to prevent the loss of significant historic buildings and structures. This should be done in conjunction with Program SS.I-16.

City of West Sacramento General Plan

The City of West Sacramento has adopted policies for identifying, evaluating and protecting historical resources in their general plan (revised and adopted December 2004) Section V Recreational and Cultural Resources Goals and Policies.

Goal F: To preserve and enhance West Sacramento's historical heritage.

Policies:

1. The City shall set as a high priority the protection and enhancement of West Sacramento's historically and architecturally significant buildings.
2. The City shall establish a historic district in the Old Broderick area and develop standards for preservation and rehabilitation of historic structures and compatible infill development.
3. The City shall cooperate in the expansion and updating of the Yolo County Historical Resources Survey.
4. The City shall work with property owners in seeking registration of historical structures and sites as State Historic Landmarks or listing on the National Register of Historic Places.
5. The City and Redevelopment Agency shall support the efforts of property owners to preserve and renovate historic and architecturally significant structures. Where such buildings cannot be preserved intact, the City shall seek to preserve the building façades.
6. Structures of historical, cultural, or architectural merit which are proposed for demolition shall be considered for relocation as a means of preservation. Relocation within the same neighborhood or to another compatible neighborhood shall be encouraged.
7. New development near designated historic landmark structures and sites shall be designed to be compatible with the character of the designated historic resource.
8. The City shall explore the possibility of establishing a city cultural center which might include a historical museum and an art gallery.
9. The City shall consider developing and maintaining the Stone Lock as a point of historical interest.

Goal G: To protect West Sacramento's Native American heritage.

Policies:

1. The City shall refer development proposals that may adversely affect archaeological sites to the California Archaeological Inventory, Northwest Information Center, at Sonoma State University.[1]

2. The City shall not knowingly approve any public or private project that may adversely affect an archaeological site without first consulting the California Archaeological Inventory [*sic*], Northwest Information Center, conducting a site evaluation as may be indicated, and attempting to mitigate any adverse effects according to the recommendations of a qualified archaeologist. City implementation of this policy shall be guided by Appendix K of the State CEQA Guidelines.[2]

3. Archaeological sites shall be protected by means of requirements in development permits requiring on-site monitoring by qualified personnel of excavation work in areas identified as archaeologically sensitive. Development work shall be required to cease in any place where artifacts or skeletal remains have been discovered until these have been examined and evaluated by a qualified archaeologist and arrangements have been made to avoid or otherwise protect valuable resources.

3.18.2.2 Environmental Setting

3.18.2.2.1 Prehistoric Context

Although the Sacramento Valley may have been inhabited by humans as early as 10,000 years ago, the evidence for early human occupation is likely buried by deep alluvial sediments that accumulated rapidly during the late Holocene Epoch. Although rare, archaeological remains of this early period allegedly have been identified in and around the Central Valley. Johnson (1967) presents evidence for some use of the Mokelumne River area, under what is now Camanche Reservoir, during the late Pleistocene Epoch. These archaeological materials and similar materials in the region have been termed the Farmington Complex. Recent work in the vicinity of Camanche Reservoir, however, calls into question whether Farmington Complex exceeds an age of 10,000 Before Present (B.P.) (Rosenthal et al. 2007:151).

Preliminary results from Tremaine & Associates' recent excavations at Sacramento City Hall (Sacramento City Hall overlies the Nisenan village of Sacum' ne, CA-SAC-38) reveal the earliest confirmed habitation of the immediate Sacramento vicinity. Obsidian hydration readings on artifacts may represent use of the site from 3000–8000 B.P. Tremaine & Associates also ran three radiocarbon assays, which yielded conventional dates of 5870, 6690, and 6700 B.P. The radiocarbon assays were taken between 9.8 feet and 11.5 feet below ground surface (Tremaine 2008:99–101).

Later periods of prehistory are better understood because of their more abundant representation in the archaeological record. Fredrickson (1973) identified three general patterns of cultural manifestations for the period between 4,500 B.P. and 3,500 B.P.: the Windmiller, Berkeley, and Augustine Patterns.

[1] Note: the name of the California Archaeological Inventory has been changed to California Historical Resources Inventory System.
[2] Appendix K no longer applies to cultural resources and the text within the original Appendix K has been stricken from CEQA statutes.

The Windmiller Pattern (4500 B.P.–3000 B.P.) shows evidence of a mixed economy consisting of the generalized hunting of game, fishing, and use of wild plant foods. Settlement strategies during the Windmiller period reflect seasonal occupation of valleys during the winter and of the foothills during the summer (Moratto 1984).

Cultural changes are manifested in the Berkeley Pattern (3500 B.P.–2500 B.P.). Technological changes in groundstone from handstones and milling slabs to the mortar and pestle indicate a greater dependence on acorns, and the presence of a wide variety of projectile points and atlatls indicates hunting was still an important activity (Fredrickson 1973).

The Berkeley Pattern was superseded by the Augustine Pattern around Anno Domini (A.D.) 500, and reflects a change in subsistence and land use patterns similar to those of the ethnographically known people of the proto-historic era. This pattern exhibits a great elaboration of ceremonial and social organization, including the development of social stratification. Elaborate exchange systems, further reliance on acorns, and a wide variety of artifacts (flanged tubular smoking pipes, harpoons, clamshell disc beads, and an especially elaborate baked clay industry, which included figurines and pottery vessels called Cosumnes Brownware) are associated with the Augustine Pattern. Increased village sedentism, population growth, and an incipient monetary economy are also hallmarks of this pattern (Moratto 1984).

3.18.2.2.2 Ethnographic Context

The study area is located at the interface of three Native American groups: the Patwin (or Wintun), the Nisenan, and the Plains Miwok. The banks of the Sacramento River and associated riparian and tule marshland habitats were inhabited by the River or Valley Patwin. The Plains Miwok and Nisenan (also called Southern Maidu), while primarily occupying territories east of the Sacramento River, used land west of the river as well (Johnson 1978; Levy 1978; Wilson and Towne 1978).

The material culture and settlement-subsistence behavior of these groups exhibit similarities, likely because of historical relationships and a shared natural environment. Historical maps and accounts of early travelers to the Sacramento Valley testify that tule marshes, open grasslands, and occasional oak groves (Jackson 1851; Ord 1843; Wyld 1849) characterized the study area. The area was generally wet in the winter and often subject to flooding; the weather was exceedingly dry in summer. Much of the floodplain was presumably sparsely inhabited, and Native Americans typically situated their larger, permanent settlements on high ground along the Sacramento and American Rivers (Bennyhoff 1977; Kroeber 1925, 1932; Levy 1978; Wilson and Towne 1978).

The Native American economy in the study area was based principally on the use of natural resources from the riparian corridors, wetlands, and grasslands adjacent to the Sacramento River. Fish, shellfish, and waterfowl were important sources of protein in the diet of these groups (Johnson 1978; Kroeber 1932). Salmon, sturgeon, perch, chub, sucker, pike, trout, and steelhead were caught with nets, weirs, lines and fishhooks, and harpoons. Mussels were harvested from the gravels along the Sacramento River channel. Geese, ducks, and mudhens were hunted using decoys and various types of nets. The majority of important plant resources in the Patwin diet came from the grasslands of the Sacramento River floodplain (Stevens 2004a: Table 1). Plants important to California Indians were also obtained from and managed in valley wetlands (Stevens 2004b:7). In addition to the staple acorn, a number of plants were important secondary food sources, including sunflower, wild oat, alfalfa, clover, and bunchgrass (Johnson 1978).

3.18.2.2.3 Historic Context

Early History

The study area is located in Yolo and Solano Counties. The two counties are part of the original 27 counties created when California became a state in 1850. Woodland serves as the county seat of Yolo County. The city of Benicia was the original county seat of Solano, but in 1858 the seat moved to Fairfield (Kyle et al. 1990).

Spanish explorers visited Yolo and Solano Counties as early as the 1700s in their search for suitable inland mission sites. In 1772, Pedro Fages passed through San Francisco Bay and the Delta and reached the San Joaquin and Sacramento rivers. Between 1793 and 1817, several other mission site reconnaissance expeditions were conducted. The first European American to travel through the area was Jedediah Strong Smith who, in the late 1820s, reported to the Hudson's Bay Company on the quantity and quality of furs in California. Joseph Walker and Ewing Young, during separate excursions, followed his general path in the 1830s. Mexican, American, and European settlers began to arrive and set down roots within the boundaries of the two counties in the 1840s and 1850s (Kyle et al. 1990).

Sacramento River

The Sacramento River played an important role in the development of Yolo and Solano Counties prior to and including Euroamerican occupation of the region. The river was a convenient landmark for the early explorations that also facilitated reconnaissance of the Sacramento Valley. The Spanish, in 1817, were the first Europeans to traverse the portion of Sacramento River that passes through the program study area, having made an exploratory boat trip up the river as far as its confluence with the Feather River (Goldfried 1988:8). This expedition was followed by a series of Spanish, Russian, British, and American land and water forays up the Sacramento River from the 1820s through 1840s (Goldfried 1988:8–9).

River traffic through the program study area became more frequent between 1839 and 1848 with the establishment of John Sutter's fort at his New Helvetia Rancho, as well other settlements upriver hosted by Peter Lassen, John Sinclair, John Bidwell's, and others (Goldfried 1988:9; Lydecker and James 2009:9; Sutter et al. 1996 [1845–1848]:1–3). The 1848 gold discovery at Coloma, however, was responsible for the vast increase in Sacramento River traffic in the program study area through the 1850s, as Sutter's embarcadero, at what is now Old Sacramento, served as the principal point of departure for persons and goods headed for the Sierra Nevada diggings. Crews frequently abandoned their ships at the embarcadero during the Gold Rush, leaving them to sink or be converted by others into warehouses, stores, and hotels on the river. (Goldfried 1988:11.)

The city of Sacramento and the communities of Washington and Riverbank/Bryte provided a lasting draw to river traffic through the 1920s because water transportation was a convenient and efficient way to move large amounts of goods and people to and from San Francisco and points beyond. River transportation from the mid-19th century through the early 20th century resulted in numerous marks along the river corridor, including ferries, wharves, shipwrecks, and numerous communities (Lydecker and James 2009:28, Figure 2-2).

Yolo County

The decline of the California Gold Rush resulted in disenchanted miners who realized they could make a greater fortune through farming and ranching rather than gold prospecting, transforming Yolo County from an isolated farming community into a booming agricultural region. Through both the mid-19th and 20th centuries, Yolo County commerce was generally agrarian in focus, the main crops being wheat, barley, and other grains. Commercial enterprises related to agriculture and livestock also sprang up during this period, furthering the development and growth of the region (Larkey and Walters 1987).

Settlement

Yolo County's first town was Fremont, founded in 1849 near the confluence of the Sacramento and Feather Rivers (south of present-day Knights Landing). It became the first county seat in 1850. After the damaging flood of 1851, the county seat was moved to the town of Washington (now part of present-day West Sacramento). Between 1857 and 1861, the county seat moved from Washington to Cacheville (present day Yolo) and back to Washington. However, in 1862, more flooding episodes had motivated the community voters to select the centrally located town of Woodland as the permanent county seat (Kyle et al. 1990).

Present-day West Sacramento experienced little growth until the early 1900s when levee construction along the Sacramento River encouraged settlement and development of the area. Early settlers included Jan Lows de Swart (holder of the Rancho Nueva Flandria land grant), and James McDowell. In 1911, the West Sacramento Company laid out the community of Riverbank (later called Bryte) just west of the Sacramento River. Shortly thereafter, plans were underway for the establishment of the town of West Sacramento (Corbett 1993).

Irrigation

Between 1911 and 1918, hundreds of miles of levees were constructed in order to control flooding in the Sacramento Valley. As early as 1892, farmers of Yolo County came together to construct levees along the Sacramento River from the town of Washington to roughly 9 miles downstream. In March 1911, the Sacramento Land Company (formerly the West Sacramento Land Company) assisted with the establishment of Reclamation District (RD) 900 in what is now West Sacramento. The formation of this district created a framework for using public funds through bonds, levies, and taxes to drain the land (Corbett 1993; Walters 1987).

Under the direction of civil engineers Haviland & Tibbetts, formation of RD 900 began. The district spanned 11,500 acres from the east-west line of the Southern Pacific Railroad (SPRR) tracks, south to the vicinity of Riverview. Construction involved installing drainage canals, levees, and pumphouses. The canals carried drainage to the pumphouses, which, in turn, moved the water over the levees into the Yolo Bypass. As the land was drained of water, the fields of tules were removed, establishing acres of agricultural land (Corbett 1993). Reclamation districts such as RD 900 frequently result in historically and functionally cohesive, patterned modifications of rural areas through their networks of irrigation works, roads, boundary markers, and buildings. Such rural historic landscapes have been documented in the Sacramento Valley, some of which—such as RD 1000 in Sacramento and Sutter counties—have been determined eligible for listing in the NRHP (Bradley and Corbett 1995; Jones & Stokes 2004; JRP Historical Consulting Services 1994; Peak 1997).

Following World War I, West Sacramento remained an unincorporated area populated primarily by small farms and a handful of industries. By the 1920s, the main east-west transcontinental highway (U.S. Highway 40, now West Capitol Avenue) traveled through West Sacramento; within a few years several hotels and motels were constructed along its route through town. During World War II, factories and other industries began to prosper along the west bank of the Sacramento River. Following the war, the region—like much of the state—experienced a housing boom that would last for several decades (Corbett 1993).

In 1987, after numerous previous attempts, the City of West Sacramento was officially incorporated. The new city included the former communities of Broderick, Bryte, and surrounding urban and rural areas on the west side of the Sacramento River into Southport (Walters 1987).

Solano County

Throughout the 19th century, land in Solano County was used primarily for wheat and alfalfa crops, cattle ranching, and some small orchards. Tall and expansive stands of wild oats attracted cattle and sheep ranchers to central Solano County and contributed to the region's early growth. Over time, however, prosperous grain and stock farms occupied land in the area. With collapse of the "wheat boom" in the 1890s, alfalfa supplanted wheat as the dominant grass crop, and it remained the area's primary crop through the turn of the 20th century. In addition to growing crops, settlers also raised poultry, pigs, sheep, dairy cows, and beef cattle (Hunt 1926; Thompson and West 1878).

The cultivation of fruits and vegetables was also extremely successful. Small orchards initially made up of a few fruit trees grown for private consumption of fruit quickly developed into large commercial orchards. Solano County continued to be a major fruit-producing region through the early twentieth century, when the region's growth and prosperity became increasingly unstable because of the faltering post-World War I economy.

Additional problems included soil exhaustion, flooding, erosion, periods of drought, and diseases harmful to the fruit trees. The combination of these forces contributed to the general decline of the fruit industry, and many orchards gave way to the bulldozer or were abandoned (Wickson 1888; Keegan 1989).

Development

Vacaville and Fairfield are two major cities in Solano County. In 1843, Mexico granted ten leagues named *El Rancho Los Putos* to Manuel Cabeza de Vaca and Juan Felipe Peña in the area that is now part of Vacaville. In 1850, settler Manuel Vaca deeded 23.3 square kilometers (9 square miles) of his land to settler William McDaniel with the proviso that a town be established and named after Vaca. Surveyors drafted plans for the new town and within a few years, the settlement featured numerous businesses that were established to serve the growing agricultural community, which was almost solely dependent on fruit production. The town incorporated in 1892 (Limbaugh and Payne 1978).

The city of Fairfield is located on lands that were originally part of the Tolenas and Suisun land grants. In 1858 Captain R. H. Waterman acquired the land and offered Solano County 16 acres for use as a county seat. The county voters accepted Waterman's offer, making the new town of Fairfield (named after Waterman's hometown in Connecticut) the new county seat, which it has been ever since. Fairfield developed more slowly than nearby communities, and it was not until the mid-20th century completion of Travis Air Force Base (originally Fairfield-Suisun Army Air Base) that the city's population began to thrive (Hunt 1926; Kyle et al. 1990).

In addition to Travis Air Force Base, the expansion of Basic Vegetable Products Company and the California State Prison contributed to the county's overall development in the 20th century. In recent years, the Vacaville/Fairfield area has grown into a bedroom community of the San Francisco Bay Area.

Irrigation

Until the middle of the 20th century, there were no large-scale irrigation systems in Solano County, and farmers relied on small irrigation efforts and annual rainfall to water their crops. In 1916, William Pierce of Suisun City proposed the damming of Putah Creek at Devil's Gate west of the town of Winters to create a 1.5-million-acre-foot reservoir in the Berryessa Valley. Pierce's idea was not adopted until more than 20 years later. In 1940, the Solano County Board of Supervisors created the Solano County Water Council to study local water needs, investigate available water sources, collect data, and make recommendations. Around the same time, the U.S. Department of the Interior, Bureau of Reclamation, and USACE began developing the Solano Project, which would tap into the Putah and Cache Creeks for water to supply the nearby agricultural and urban areas. The project consisted of three main facilities: the Monticello Dam and Lake Berryessa, the Solano Diversion Dam, and the Putah South Canal, which originates at the diversion dam and conveys water south to Solano County. All three projects were completed in 1957. The water provided by the Solano Project, in conjunction with later efforts, allowed continued urban and agricultural growth in the county (Goerke-Shrode 2002; Harnes 2002).

3.18.3 Environmental Consequences

This section analyzes the effects relating to cultural resources for the proposed program. It describes the methods used to determine the effects of the program and lists the thresholds used to conclude whether an effect would be significant. Measures to mitigate (i.e., avoid, minimize, rectify, reduce, eliminate, or compensate for) significant effects accompany each effect discussion.

3.18.3.1 Assessment Methods

3.18.3.1.1 Cultural Resources Identification Efforts

The present assessment of environmental consequences differs from many NEPA/CEQA cultural resource assessments for proposed projects with discrete footprints and straightforward implementation horizons. The proposed program identifies several categories of actions that have the potential to affect cultural resources, but at the present level of detail available these activities cannot be delineated into discrete project footprints. At the same time, the individual projects under the program are not necessarily expected to result in effects on cultural resources throughout every portion of the program study area. Furthermore, the proposed program consists of an array of actions that would be implemented—sometimes repeatedly—over the course of several years in various locations within the program study area. The Corps has determined that implementation of a PA and Historic Properties Management Plan (HPMP) is the most effective way to accommodate both the program requirements and compliance with CEQA, NEPA, and the NHPA, as permitted at 36 CFR 800.4(b)(2) and 800.14(b). The HPMP will allow the incremental identification, documentation of effects on, and mitigation of significant effects on historic properties as a result of the program.

Under this compliance strategy, complete field examination of the program study area is unnecessary, although enough background data need to be collected to place cultural resource effects into context. Efforts in this regard consist of literature reviews and records searches, historic map research, and consultation with Native Americans. No pedestrian surveys have been conducted for this program analysis.

Records Search

ICF International staff requested a records search in October 2007 at the Northwest Information Center and the North Central Information Center of the California Historical Resources Information System located at Sonoma State University and California State University, Sacramento, respectively. The research consisted of a database search of all previously recorded sites and studies within the study area, established as a 0.25-mile-wide corridor from the center of the river to along both shorelines for the entire length of the study area, including the DWSC. The search also consulted the current listings for the NRHP, the CRHR, Historic Spots in California (Kyle et al. 1990), and pertinent historic inventories and historic maps (Anonymous 1877; Department of Parks and Recreation 1976, 1996; North Central Information Center n.d.; Office of Historic Preservation 2007a:12–14, 2007b:2, 11–14, 31, 2007c:21–70, 2007d:155–157; U.S. Geological Survey 1907, 1908).

Shipwrecks Database

ICF International consulted the California State Lands Commission's Shipwrecks Database (2009) to determine whether historic shipwrecks may be present in the program study area. The database was searched by selecting Yolo County in the search field, which generated a list of 12 shipwrecks in Yolo County. The database search yielded latitude and longitude coordinates for 11 of the shipwrecks, which were plotted using an online mapping program (http://www.itouchmap.com/latlong.html) to determine whether any of the shipwrecks were in the study area.

Native American Consultation

In January 2008, ICF International cultural resources staff contacted the Native American Heritage Commission (NAHC) to request a search of their Sacred Lands File. The NAHC staff responded in January 2008 with a list of Native American contacts for both Yolo and Solano Counties and the results of the sacred lands data base research that was negative for findings in the program corridor.

The NAHC contact list included the following federally recognized Native American tribes:

- Rumsey Indian Rancheria of Wintun Indians
- Cortina Band of Wintun Indians (including the Wintun Environmental Protection Agency)
- Ione Band of Miwok Indians

The NAHC also provided contact information for the following federally non-recognized Native American groups and individuals:

- Kesner Flores
- Wilton Miwok Rancheria

ICF International staff sent letters to the Native American contacts on the lists provided by NAHC. The correspondence included a map depicting the program corridor, a brief description of the

proposed program, and a request for the contacts to share any knowledge or concerns they may have regarding cultural resources in or adjacent to the study area. ICF International received a letter response dated April 2008 from Mr. Marshall McKay, Tribal Chairman for the Rumsey Band of Wintun Indians. Mr. McKay's letter stated his gratitude for the letter notification about the proposed levee alternatives and that he was not aware of any sites of religious or cultural importance in the program corridor. Mr. McKay also stated that the Rumsey Indian Rancheria of Wintun would like to be notified of any cultural finds unearthed during construction actions. ICF International staff placed follow-up telephone calls to the letter recipients on June 5, 2009. Voice messages were left with the contacts. To date, no return phone calls have been received.

Results

The records search identified numerous studies previously conducted in the study area. Most were small areal studies that included a portion of the study area. However, a limited number of the previous studies were linear studies conducted along a larger portion of the levee or adjacent to it. The more recent studies were located in areas that incorporated portions of the project-level areas and will be discussed in the project-level analysis below. The majority of the study area has not been subjected to cultural resource studies more recently than 1993, and the three primary studies conducted along the DWSC were conducted in 1976 and 1985 (Seldomridge and Smith-Madsen 1976; Werner 1985a, 1985b). Studies of submerged cultural resources along study area portions of the Sacramento River have also been conducted (Allan 2002a, 2002b; Allan et al. 2002; California State Lands Commission 1988).

Having been conducted more than 10 years ago, the majority of these previous studies are now outdated. Since the time of those studies, ground surface conditions in the study area may have changed, and built environment features such as buildings and structures, and or linear features are likely to have become at least 45 years old[3]. Advancements in the field of cultural resource management make it likely that previously unidentified or unrecognized resources would be identified if a survey were to be conducted today. In other words, the passage of 10 years or more renders it likely that previously unidentified cultural resources would be identifiable at present in portions of the study area. Therefore, the majority of the program corridor is considered in need of being resurveyed either at an intensive or at least a reconnaissance-level of investigation.

Setting aside the need for a comprehensive survey of the program study area, Table 3.18-1 summarizes the known cultural resources located in the program study area.

[3] Although the NRHP typically only considers properties that are 50 years or older for listing, the Office of Historic Preservation (1995:2) employs a 45-year threshold for the recordation of cultural resources because "there is commonly a five year lag between resource identification and the date that planning decisions are made."

Table 3.18-1. Cultural Resources Located in the Program Study Area by Reach

Resource Name/Number	Resource Description	Resource Eligibility
Sacramento Bypass Levee		
YOL-HRI-8/242	Historic—Sacramento Weir and Yolo Bypass	Determined eligible for NRHP/CRHR listing
Sacramento River North Levee		
CA-YOL-24	Prehistoric mound site	Unevaluated
CA-YOL-25	Prehistoric mound site	Unevaluated, site appears to have been destroyed (Bouey with Herbert 1990:40)
CA-YOL-HRI-8/219	Historic- water tower	Unevaluated
CA-YOL-HRI-8/221	Historic—John White House 610 Second Street	Not eligible; has been demolished (Les 1986:1)
P-57-000423	Historic (waterside) remains of four wood dolphins and pilings, remains of Texas Company wharf	Unevaluated
CA-YOL-27	Prehistoric mound site	Unevaluated
Yolo Bypass Levee		
P-57-000400	Historic—California Pacific Railroad	Unevaluated
Port North Levee		
C-1112	Prehistoric—single human vertebrae	Unevaluated
Port South Levee		
No resources previously recorded and no new resources identified.		
Sacramento River South Levee		
P-57-000425	Historic—waterside remains of wood pilings, possible remains of Lufkin Landing wharf.	Ineligible
P-57-000607 (CA-YOL-222-H)	Historic—waterside wharf remnants	Recommended ineligible
CA-YOL-132	Prehistoric midden site	Unevaluated
South Cross Levee		
No resources previously recorded		
P-48-787	Historic Prospect Island Levee	Unevaluated

In addition to the cultural resources identified in Table 3.18-1, the State Lands Commission's shipwreck database and California State Lands Commission (1988:47, 53, 59, 77, 87) indicate that approximately 16 shipwrecks have been reported in the study area. Their presence in the study area has not been confirmed, however. The shipwrecks are subject to displacement by river currents, salvaging, and destruction by waterside development.

3.18.3.2 Determination of Effects

3.18.3.2.1 Federal Criteria

According to 36 CFR 800.5, an undertaking would have an adverse effect on historic properties if the effect alters the characteristics[4] that make a property eligible for inclusion in the NRHP. Such effects also would be considered adverse under NEPA. Adverse effects can occur when prehistoric or historic archaeological sites, structures, or objects listed in or eligible for listing in the NRHP are subjected to the following phenomena:

- physical destruction of or damage to all or part of the property;
- alteration of the property, including restoration, rehabilitation, repair, maintenance, stabilization, hazardous material remediation, and provision of handicapped access, that is not consistent with the Secretary of the Interior's Standards for the Treatment of Historic Properties (36 CFR 68) and applicable guidelines;
- removal of the property from its historic location;
- change in the character of the property's use or of physical features within the property's setting that contribute to its historic significance;
- introduction of visual, atmospheric, or audible elements that diminish the integrity of the property's significant historic features;
- neglect of the property that causes its deterioration, except where such neglect and deterioration are recognized qualities of a property of religious and cultural significance to a Native American tribe or Native Hawaiian organization; or
- transfer, lease, or sale of the property out of Federal ownership or control without adequate and legally enforceable restrictions or conditions to ensure long-term preservation of the property's historic significance.

3.18.3.2.2 State Criteria

CEQA defines a significant impact on cultural resources in 14 CCR 15064.5(b) (1) and (2) as one with the potential to cause a substantial adverse change in the significance of a historical resource or unique archaeological resource. Substantial adverse change in the significance of a resource means the physical demolition, destruction, relocation, or alteration of the resource or its immediate surroundings such that the significance of the resource would be materially impaired. The significance of a historical resource is materially impaired when a project results in demolition or material alteration in an adverse manner of those physical characteristics of a resource that:

- convey its historical significance and that justify its inclusion in, or eligibility for inclusion in, the CRHR;

[4] Cultural resource managers often refer to these characteristics as character-defining elements or features. Character-defining features are those characteristics of a historic property, historical resource, or unique archaeological resource that convey its significance; the loss of character-defining elements impedes a property's ability to convey its historical significance. The importance of character-defining elements in cultural resource assessments is made clear in *National Register* Bulletin 15, which mentions "character" in this context 42 times (Andrus and Shrimpton 1997).

- account for its inclusion in a local register of historical resources pursuant to PRC 5020.1(k) or its identification in a historical resources survey meeting the requirements of PRC 5024.1(g), unless the public agency reviewing the effects of the project establishes by a preponderance of evidence that the resource is not historically or culturally significant; or
- convey its historical significance and that justify its eligibility for inclusion in the CRHR as determined by a lead agency for purposes of CEQA.

3.18.3.3 Effects and Mitigation Measures

This section describes the potential effects on cultural resources that would result from the proposed program and the mitigation measure that would either reduce the effects to less-than-significant levels or would reduce the severity of the effect. These effects and mitigation measures would apply to the entire study area and all proposed levee alternatives. For buried cultural resources, the project alternatives that seem likely to pose the least amount of ground-altering disturbance are the use of the slurry wall and the rock slope protection. However, these methods still require staging areas, access, heavy equipment, and vegetation clearing. As a result, the following effects and mitigation measures would still apply. Additionally, if a slurry wall trench is excavated into native soils beneath the levee, the excavation could intersect buried archaeological resources, if present.

3.18.3.3.1 No Action Alternative

Under the No Action Alternative, it is presumed that no ground-disturbing activities associated with levee repair and alternatives would occur. However, it is possible that without the planned levee alternatives, the levee could fail and a cultural resource could be in the path of an inundation of debris and mud from that failure that could cause significant damage to or the complete destruction of the resource. Furthermore, emergency efforts to stop and repair a failed levee potentially would cause the same or more significant effects than those described for the proposed program. Whether these events would transpire and affect cultural resources is unknown and therefore further analysis of these effects would be speculative. Federal agencies responsible for levee repairs would be responsible for compliance with Section 106, as would local governments responsible for carrying out Federal programs.

3.18.3.3.2 Flood and Recreation Program Alternatives

Effect CR-1: Effects on Architectural (Built Environment) Resources and Cultural Landscapes

Proposed flood and recreation program alternatives may occur near built-environment resources (including historic levees) cultural landscapes that are more than 45 years old and may be eligible for listing in the NRHP or CRHR. The implementation of alternatives may lead to physical demolition, destruction, relocation, or alteration of resources that are potentially NRHP- and/or CRHR-eligible. An inventory and evaluation of the resources in the proposed alternative areas is necessary to determine the eligibility of the known or unknown resources and to assess the potential direct effects that may be significant.

The program-level PA and attached HPMP mentioned in Section 3.18.3 define the tasks necessary to identify, determine the eligibility of, and treat historic properties in the APE.

Program Alternatives Associated with This Effect

Implementation of these alternatives can cause Effect CR-1:

Program	Alternative	
Flood	▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Rock slope protection ▪ Jet grouting ▪ Seepage berm ▪ Closure ▪ Setback levee	▪ Flood wall ▪ Slurry cutoff wall ▪ Relief wells ▪ Interior drain ▪ Slope flattening ▪ Sheet pile wall ▪ Stability berm
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, Effect CR-1 could occur in all the program reaches: Sacramento River North, Sacramento River South, Port North, Port South, South Cross, DWSC East and West, Sacramento Bypass, and Yolo Bypass.

Effect CR-1 Finding	Finding with Mitigation
Significant	Significant and unavoidable

Effect CR-2: Change in the Significance of an Archaeological Resource

The proposed program study area has not been recently (within the last 10 years) or completely inventoried for the presence of cultural resources and therefore may contain significant archaeological resources as defined by Section 106 of the NHPA, NEPA, and CEQA. In addition, as outlined in Table 3.18-1, three previously recorded prehistoric archaeological sites (CA-YOL-24, CA-YOL-25, and CA-YOL-27) are located in the area encompassed by the Sacramento River North Levee, although CA-YOL-25 is thought to have been destroyed (Bouey with Herbert 1990:40). In addition, several shipwrecks have been identified and may still be extant in the program study area. Ground-disturbing and construction activities associated with the levee alternatives may result in damage to or destruction of these or other archaeological resources that may be eligible for the CRHR or NRHP. The physical damage to, or the destruction of, an eligible archaeological resource that results in a significant change in the significance of that resource would constitute a significant effect under CEQA (14 CCR 15064.5) and a significant effect under Section 106 of the NHPA and NEPA. Therefore, the effect on archaeological resources would be significant and unavoidable.

As stated earlier in this section, the program-level PA stipulates the preparation of a Historic Properties Management Plan (HPMP), which defines the tasks necessary to identify, determine the eligibility of, and treat historic properties in the APE.

Program Alternatives Associated with This Effect

Implementation of these alternatives could cause Effect CR-2:

Program	Alternative	
Flood	▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Rock slope protection ▪ Jet grouting ▪ Seepage berm ▪ Closure ▪ Setback levee	▪ Flood wall ▪ Slurry cutoff wall ▪ Relief wells ▪ Interior drain ▪ Slope flattening ▪ Sheet pile wall ▪ Stability berm
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, Effect CR-2 could occur in all the program reaches: Sacramento River North, Sacramento River South, Port North, Port South, South Cross, DWSC East and West, Sacramento Bypass, and Yolo Bypass.

Effect CR-2 Finding	Finding with Mitigation
Significant	Significant and unavoidable

Effect CR-3: Disturbance of Native American and Historic-Period Human Remains

Only approximately 10% of the program corridor has been subjected to a formal pedestrian survey considered adequate for the inventory of cultural resources present in the APE. It is not known whether buried human remains are located in the program study area corridor. However, the program corridor is located within a geographic area that is considered of moderate to high sensitivity for archaeological cultural remains, including burials. The potential for buried human remains to be unearthed and disturbed during ground-disturbing activities that would be associated with levee repair and alternative construction within the study area is considered high. The disturbance of any human remains is considered a significant effect. Implementation of the human remains discovery provisions in the program HPMP would likely reduce the severity of this effect, but it would still be considered a significant and unavoidable effect.

Program Alternatives Associated with This Effect

Implementation of these alternatives could cause Effect CR-3:

Program	Alternative	
Flood	▪ Levee raise (in place) ▪ Levee raise (adjacent) ▪ Levee raise (full) ▪ Rock slope protection ▪ Jet grouting ▪ Seepage berm ▪ Closure ▪ Setback levee	▪ Flood wall ▪ Slurry cutoff wall ▪ Relief wells ▪ Interior drain ▪ Slope flattening ▪ Sheet pile wall ▪ Stability berm
Recreation	▪ Trails ▪ Riverside parks	▪ Developed water access ▪ Special projects

Affected Reaches

Although different flood and recreation program alternatives are proposed for the reaches, Effect CR-3 could occur in all the program reaches: Sacramento River North, Sacramento River South, Port North, Port South, South Cross, DWSC East and West, Sacramento Bypass, and Yolo Bypass.

Effect CR-3 Finding	Finding With Mitigation
Significant	Significant and unavoidable

Mitigation

As stated earlier in this section, the resolution of any adverse effects will be addressed in accordance with the stipulations of the program PA between the Corps, WSAFCA, and SHPO. Execution of the PA, which is accomplished upon the signing of the document by all consulting and concurring parties, constitutes compliance with the Section 106 consultation process and for the proposed program will be completed before the Record of Decision is signed. The HPMP, which is an attachment to the program PA, provides the specific, detailed measures to be implemented for the project. As directed by the Corps, and in consultation with the SHPO, the WSAFCA or its agent shall implement the HPMP. Following are expected mitigation measures in the HPMP.

- Develop and monitor implementation of architectural criteria to guide the design process within the APE.
- Prepare Historic American Building Survey/Historic American Engineering Record (HABS/HAER) documentation.
- Conform to the Secretary of the Interior's Standards for Rehabilitation and Guidelines for Rehabilitating Historic Buildings in the Event of Relocation.
- Develop and monitoring implementation of protection measures during construction.
- Conduct a post-construction condition assessment of the APE;
- Develop public interpretive material.

- Prepare a Mitigation Implementation Plan for each phase of the project to be used as a communication tool for coordinating construction activities with the prescribed protection and treatment measures.
- Expose archaeological features or deposits within the APE that could be affected by the project.
- Sample archaeological features or deposits to determine whether they meet research design requirements.
- Evaluate the significance of any archaeological resources that are identified.
- Conduct data recovery procedures for any eligible properties.
- Devise strategies for the avoidance of significant cultural resources during program implementation.

Chapter 4
CHP Academy Early Implementation Project

4.1 Introduction

This chapter provides the project-level analysis for the CHP Academy EIP. The analysis of effects for the CHP Academy EIP tiers directly from the program analysis. To avoid repetition and for communication efficiency, background information that is general for the study area or common for all reaches or alternatives is summarized in this chapter and the reader is referred to Chapter 3 for further discussion. Site- specific setting and environmental consequence information is provided here to more fully explain the effect and the mitigation measures that would be implemented to reduce that effect. As stated in Chapter 3 for the WSLIP program-level analysis, the baseline environmental conditions used in this EIP analysis consist of the existing physical environment as of January 28, 2009, when WSAFCA published the Notice of Preparation (NOP) to prepare an EIR with the State Clearinghouse. USACE published a Notice of Intent (NOI) to prepare an EIS in the *Federal Register* on January 27, 2009.

Note: For readability, the pages in this chapter for the project-level analysis are numbered consecutively. The resource topics follow the same sequence as the Chapter 3 program analysis but the heading numbers vary based on the need for up-front text specific to the project-level analysis.

4.2 Purpose and Need

The purpose of implementing treatments at the CHP Academy site is to achieve a minimum of 200-year flood protection at the site (0.5% AEP), which would ultimately help reduce flood risk for the entire city of West Sacramento.

The approach to meet this purpose, as with the programmatic approach, is to provide an evaluation of the CHP Academy EIP site, develop alternatives for improvement, and provide a basis for partnerships with Federal and state agencies to implement improvements that meet the flood protection and compatible recreation and open space goals. The objectives under this purpose and approach are to:

- construct levee improvements as soon as possible to reduce flood risk as quickly as possible;
- construct improvements that are politically, socially, economically, and environmentally acceptable;
- provide recreation and open space elements for the city that are compatible with flood improvement actions; and
- ensure continuing Federal assistance for levee repairs and maintenance.

The general purpose of and need for action at the CHP Academy site are the same as described for the overall WSLIP in Chapter 1 (Section 1.4). Specific levee deficiencies at this site are through-seepage, geometry, and under-seepage, along with short reaches of instability. Flood and recreation improvements implemented under the CHP Academy EIP would assist in incrementally achieving

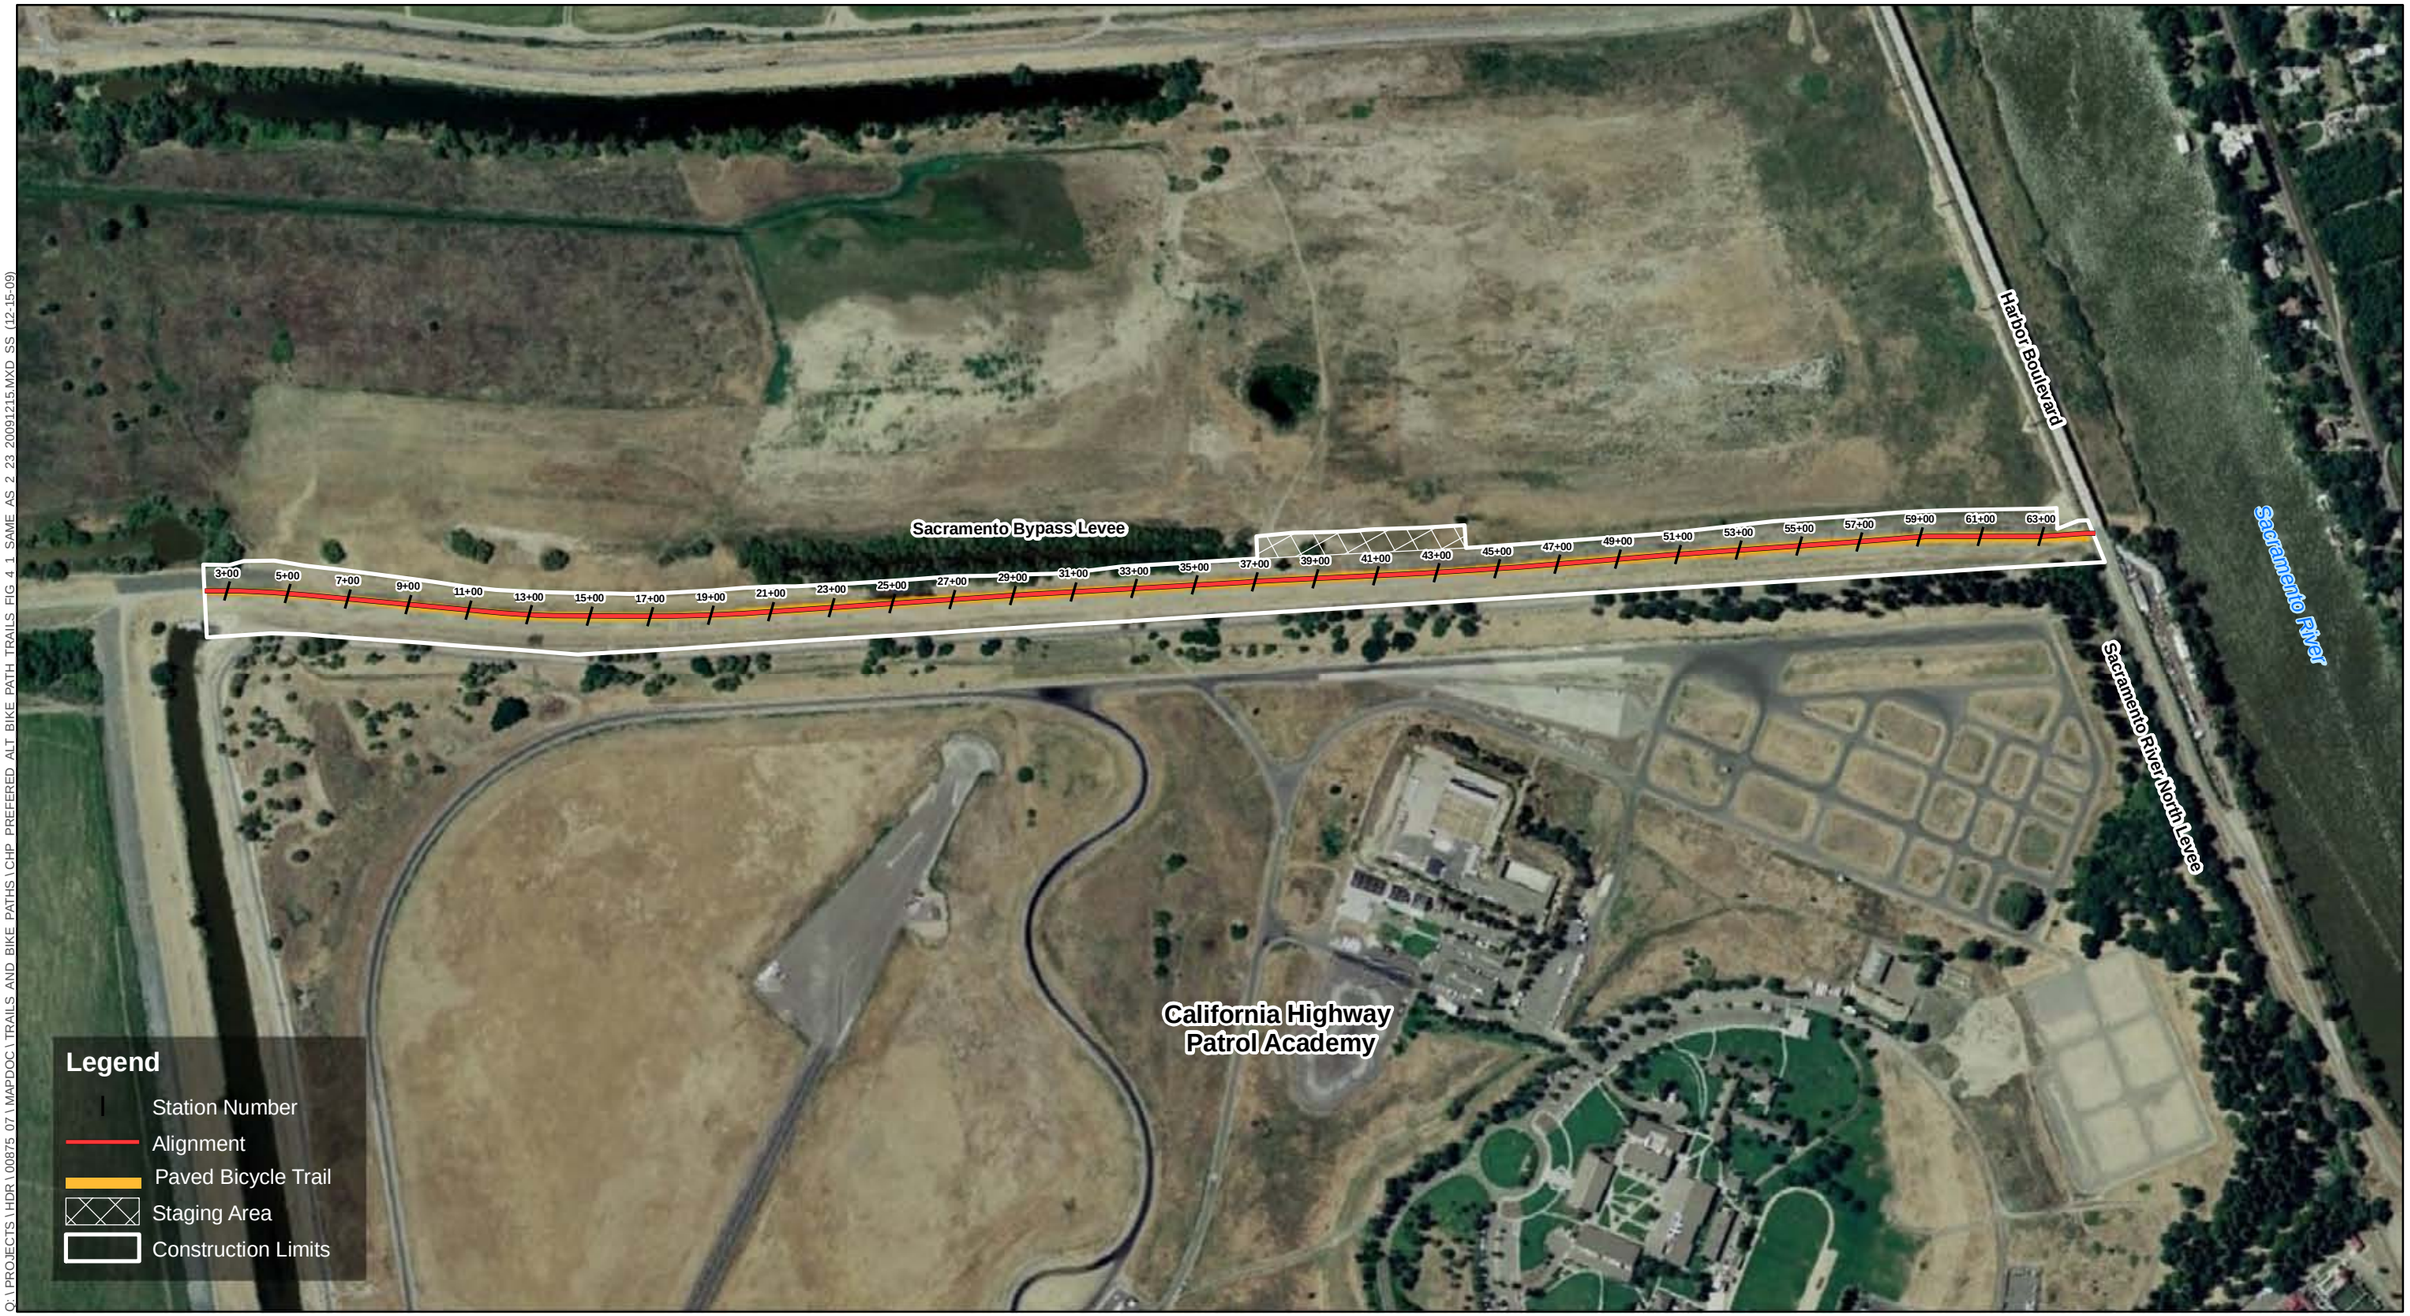
the purpose of and need for the WSLIP and would reduce local flood risk in the proximity of the project.

4.3 Alternatives

4.3.1 CHP Academy Project Alternatives

4.3.1.1 Introduction

The CHP Academy EIP area is approximately 6,500 feet long and is located on the Sacramento Bypass Levee, (Figure 4-1). The easternmost 1,200 feet of the waterside slope of the levee (adjacent to the weir) is lined with a concrete cap. This concrete cap prevents the levee from eroding when the weir is open and water is allowed to enter into the Sacramento Bypass from the Sacramento River. A stability berm and an interior drain system installed as part of the West Sacramento Project in 1999 runs the length of the levee on the landside. As stated above, deficiencies at this site are through-seepage, geometry, and under-seepage, along with short reaches of instability.



4.3.1.2 CHP Academy Alternatives Screening

WSAFCA considered a range of program alternatives that would address the deficiencies at the CHP Academy site. The improvement alternatives were narrowed as listed below.

- Alternative 1: slope flattening, slurry cutoff wall
- Alternative 2: slope flattening, seepage/stability berm
- Alternative 3: stability berm with interior drain, relief wells

As introduced earlier in Section 2.2.2.3, WSAFCA established and applied nine criteria to qualitatively evaluate the alternative improvements and eliminate those alternatives that did not adequately meet the criteria. The criteria are below.

- **Meet the Project Objectives to Reduce Risk**—The objective of the project is to alleviate through- and under-seepage concerns on this portion of the levee, as well as stability and geometry. Alternatives that provide the greatest reduction in subsurface water pressure (measured as the exit gradient of water moving through the soil) and improve slope stability and geometry relative to current levee standards are the most favored. Evidence of seepage has been observed at this site during previous high-water events.
- **Availability of Funds**—Levee repairs are necessary throughout the Sacramento River watershed. Federal and state monies as well as local matching monies must be spent thoughtfully to enable all the necessary levee improvements to be constructed. The preferred alternative would allow WSAFCA to implement the action through existing revenue sources without a cost-sharing partner or through demonstrating compatibility and creditability with state and Federal funding sources.
- **Scalability of Construction**—The scalability of an alternative refers to the ability of the design and construction documents to be increased or decreased if issues arise with contract financing or an unstable construction bid climate. Alternatives such as cutoff walls or seepage berms that can be partially constructed, as funds allow, are more desirable than setback levees or relief well

Note: This figure is the same as 2-23 and is provided here for your convenience.

systems that are not compatible with partial construction techniques. Alternatives that facilitate the ability to connect future adjacent improvements to the selected site without significant rework or cost are favored.

- **Real Estate Requirements**—An alternative that requires large land acquisition from private owners, such as a setback levee, is potentially cost prohibitive. Real estate acquisition may also present challenges with public and political acceptance. Temporary construction easements would not create as many issues as the need for permanent easements or fee-title acquisition. Alternatives requiring little to no additional flood protection easement are favored.
- **Land Use Compatibility**—The future land use of the areas on or adjacent to the proposed levee improvements should be taken into consideration. If known projects exist or have been approved by the City along the affected levee reach, alternatives should be evaluated with consideration of the degree to which they disrupt or interfere with such land uses. Alternatives that do not require modification to existing land-use plans adjacent to the site are favored.
- **Permit Requirements**—Permit requirements can greatly influence how soon an alternative can be implemented and flood protection can be provided. Projects that do not require numerous complex Federal, state, or local authorizations are favored.
- **Environmental Constraints (such as biological and cultural resources)**—Locations along the river support habitat critical to threatened or endangered species such as the valley elderberry longhorn beetle or the giant garter snake. In addition, the river corridor has a rich history of human use and contains cultural resources significant to that history. The environmental review and permitting process for effects to these types of resources can be lengthy and delay construction of improvements. Therefore, alternatives that avoid effects to these resources are preferable.
- **Integration of Multiple Objectives**—Propositions 50 and 84 include the goals of integrating multiple objectives to address a range of public policy priorities, leverage funding, integrate and coordinate projects, and achieve economies of scale. The community benefits from the coordination of levee improvements with other planned projects as it would enable the City to realize other goals in concert with flood protection goals and provide potential economies of scale, while minimizing disruption. Alternatives that facilitate realization of other objectives within the project area are favored.
- **Evolving Technical Policy**—The risks associated with evolving technical policy are also considered. Future policy may require seismic stability of levees or vegetation-free zones that vary from current conditions. These may also eventually lead to stricter design guidelines for levee construction protecting highly urbanized areas. The potential effects of this evolving policy are included in the consideration of alternatives. Alternatives that have low risk of major reinvestment based on any foreseeable change in acceptance criteria are favored.

In some cases, an alternative may partially meet a criterion while another meets it more fully. For this reason, the designations of more favorable (MF) and less favorable (LF) were applied to each criterion for each alternative. Table 4-1 below provides the results of the criteria evaluation.

Table 4-1. Evaluation of CHP Academy EIP Alternatives

Evaluation Criteria	Alternative 1 (slope flattening, slurry cutoff wall)	Alternative 2 (slope flattening, seepage/stability berm)	Alternative 3 (stability berm with interior drain, relief wells)
Meet the Project Objective to Reduce Risk	MF	MF	MF
Availability of Funds	LF	LF	LF
Scalability of Construction Project	MF	LF	LF
Real Estate Requirements	MF	LF	LF
Land-Use/Project Compatibility	MF	LF	LF
Permit Requirements	LF	LF	LF
Environmental Constraints	MF	LF	LF
Integration of Multiple Objectives	MF	LF	LF
Evolving Technical Policy	MF	MF	MF

Alternative 1 appears to be the most favorable levee improvement strategy based on this qualitative evaluation of various potential levee repair alternatives for the CHP Academy site. Repairing this site through the installation of a slurry cutoff wall requires the smallest temporary and permanent footprint for implementation. The estimated costs of constructing the improvements for all the alternatives are $5 million to $10 million. However, the reduced footprint of Alternative 1 will likely result in reduced real estate acquisition (and costs) and environmental impacts. Further, the installation of a soil-bentonite cutoff wall is compatible with the recreation features planned by the City for this location. Based on these considerations Alternative 1 is the proposed levee improvement strategy for the CHP Academy site.

Alternatives 2 and 3 appear to be the least favorable alternatives. Both of these alternatives require the installation of a seepage and/or stability berm. In most cases, berms require some amount of additional real estate to implement. The acquisition of additional real estate often results in increased projects costs as well as additional environmental impacts associated with the removal of vegetation and other habitat. For Alternative 2, the considerable amount of additional real estate required would affect the functionality of the CHP Academy located immediately adjacent to this reach of levee, and for this reason the alternative is not carried forward. For Alternative 3, the installation of relief wells would require water quality permitting, increased operation and maintenance costs, and has the potential to impact operations of the pump station located near the site.

Based on the screening process, two of the alternatives were developed for the CHP Academy EIP to be carried forward for study in the EIS/EIR. Table 4-2 provides detail for the levee stationing and treatments proposed for each alternative. The alternatives (in addition to no action) are identified below.

- **CHP Academy Applicant Preferred Alternative (APA).** The installation of a slurry cutoff wall combined with slope flattening (Alternative 1, above).
- **CHP Academy Alternative B.** The construction of a seepage berm with an interior drain combined with relief wells (Alternative 3, above).

The proposed recreation program improvements are the same for both the CHP Academy APA and CHP Academy Alternative B. Chapter 4 of this EIS/EIR includes an analysis of the effects of the CHP Academy APA, CHP Academy Alternative B, and the No Action Alternative. A detailed description of both the flood program and recreation program improvements follows the alternative screening discussion.

Table 4-2. CHP Academy EIP Flood Improvement Alternatives

EIP	Station Ranges		Deficiencies	APA Levee Treatments	Alt B Levee Treatments
CHP Academy EIP (2+20 to 64+78)	2+20	18+00	Geometry	Waterside slope flattening	Stability berm with interior drain and relief wells
	18+00	60+00	Through-seepage, under-seepage, stability, geometry	Slurry cutoff wall and waterside slope flattening	Stability berm with interior drain and relief wells
	60+00	64+78	Through-seepage, stability, geometry	Slurry cutoff wall and waterside slope flattening to weir	Stability berm with interior drain and relief wells

4.3.1.3 No Action Alternative

Under the No Action Alternative, no flood or recreation improvements would be implemented at the CHP Academy site, West Sacramento would remain at flood risk, USACE levee vegetation guidance would be complied with, and current flood O&M activities would continue. A more complete discussion of no action as it applies to the WSLIP and this EIS/EIR is described in Section 2.4, with relevant detail provided below for the project-level analysis. Refer to Section 2.4 for discussion about the definition of no action, possibility of future Federal or state action, relationship of flood map modernization to no action, and USACE levee vegetation policy relative to no action.

4.3.1.3.1 Consequences of Levee Failure

Assuming that no levee repair or strengthening would occur under the No Action Alternative means that the Sacramento Bypass levee would remain or become more susceptible to failure as a result of identified deficiencies of seepage, geometry, and slope instability. As stated previously, evidence of seepage has been present at this site during high-water events. These conditions could cause portions of the levee to fail, triggering widespread flooding, extensive damage to the city's existing residential, commercial, agricultural, and industrial structures, and potential loss of life and property. Extensive damage to utilities, roadways, major interstate transportation corridors, and other infrastructure systems would also likely occur.

The magnitude of the flood damage would depend upon the nature of the levee failure, severity of the storm, and river flows at the time of a potential levee failure. A failure of this levee would first flood the CHP Academy site, and then overland flow would inundate the established residential communities of Bryte and Broderick, flood of the commercial core of West Sacramento, and ultimately could inundate the Southport area. The elevations are higher in the north sector of the city, meaning the land surface generally falls from the north and east toward the south and west.

Therefore, a breach at this location could flood the entire city as the north basin would fill followed by the south basin.

Flood depth maps prepared for West Sacramento indicate that under a 100-year flood event scenario, inundation levels would range from 1 foot to 10 feet in the north basin, with most in the range of 1 to 5 feet, about 20% from 5 to 10 feet, and less than 10% less than 1 foot. Figure 2-1 shows the ultimate estimated inundation depths for a 100-year flood event.

In 2006, two hypothetical levee failures were analyzed for West Sacramento utilizing 100-year water surface elevations and hydrology. This analysis was performed to assist the City in its flood emergency preparedness planning. One failure was located in the northern part of the city, on the Sacramento River North Levee, and these results are reasonably representative of the CHP Academy site (failure locations are shown in Figures 2-2 and 2-3). (Wood Rodgers 2006.)

The analysis indicates that a levee failure on the Sacramento River North Levee during a 100-year event would flood the entire north area with at least 1foot of water within 24 hours, at which point vehicular evacuation would become severely limited (a depth of 1 foot is regarded as impassable from the standpoint of vehicular traffic). Certain neighborhoods close to the levee failure would lose access to evacuation routes within three hours of levee failure. Figure 2-2 shows the estimated time to 1-foot inundation depths throughout the northern area. Within3 days, floodwater depths would reach 3to 10 feet, depending on land surface elevation (as shown in Figure 2-1). Floodwaters would flow from north to south, seeking the lowest topographical elevation, and eventually discharge into the DWSC. The study estimates that floodwaters would begin to spill into the DWSC less than 24 hours after the breach. Modeling indicates that the DWSC could absorb up to 20,000 cubic feet per second (cfs) in discharge flow from waters flooding the north area of the city before overtopping and flooding the Southport area. (Wood Rodgers 2006.)

Levee failure and subsequent flooding of the city of West Sacramento would affect the entire city, jeopardizing lives, and would cause substantial damage to structures, contents, and other property such as landscaping and automobiles. As of 2005, a population of 40,439 was living in 15,448 housing units within the city (Sacramento Area Council of Governments 2008a and 2008b). All of these residents could be displaced by a catastrophic flood event. Additionally, the city is home to 30,655 jobs (Sacramento Area Council of Governments 2008c), 734 commercial and industrial structures, 46 public structures and 27 park facilities, which would all be affected by a flood event (HDR Engineering 2009). Environmental and agricultural resources could also sustain major damage in a flood event; 22.6% of the land area within the city is either farmland or open space (City of West Sacramento 2009). If a catastrophic flood event occurred resulting in inundation up to 15 feet, land damages are estimated to be $237,763,648 and structural damages could be up to $1,750,118,102 (PB 2007). These values are based on the 100-year event.

A flood event could cause severe public health hazards as well. Flooding in the city could upset and spread stored hazardous materials, creating hazardous conditions for the public and the environment. Flood damage to homes and other structures could render them dangerous, due to structural damage as well as contamination. Additionally, the floodwaters and ponds left behind could provide a wide breeding ground for mosquitoes and other disease vectors. Effects to the water supply system could be particularly severe in a flood event, and could leave residents and businesses without a reliable water supply for a significant amount of time, as a single break in a water delivery pipe or main could contaminate the entire city's water supply. A major flood event

could also result in substantial stress or disruption to the region's emergency response capacity, hospital services, and other critical lifelines of West Sacramento.

During the recovery period after a flood event, West Sacramento residents would require temporary housing, and displacement of many or all occupants would occur while levees, buildings, and other infrastructure were repaired. Businesses, social services, and other employers occupying affected structures would be forced to relocate. The potential number of displaced residents (over 40,000) and businesses (over 30,000 jobs) is so large that the demand for temporary quarters would likely exceed the available supply of vacant buildings surrounding the West Sacramento area. Thus, many displaced residents and businesses may be forced to relocate to areas a considerable distance from West Sacramento, resulting in substantial intermediate-term and long-term economic impacts on the West Sacramento area and its people. These impacts include changes in employment numbers and patterns, business and personal incomes, tax revenues, and regional economic activity.

A flood event in West Sacramento would also disrupt state and interstate highway, rail, and shipping traffic, causing long-term effects on the region's and the state's economy and ability to move people and goods. West Sacramento has one of the most comprehensive transportation networks on the west coast. Its central geographic location and extensive north-south and east-west highway access has made it a major distribution center. High volumes of truck and passenger traffic pass through the city on Interstate 80 and US 50/Business 80 every day, with truck traffic transporting approximately $63 billion worth of cargo annually through West Sacramento (HDR Engineering 2009). Major transcontinental rail lines passing through the city provide commercial and passenger rail service to all parts of the nation, and the Port of West Sacramento runs domestic and international shipping services (City of West Sacramento 2009). Approximately 9.3 million tons of rail freight valued at approximately $5 billion travels through West Sacramento annually (HDR Engineering 2009). Flooding of this transportation and distribution infrastructure would cut off major statewide and interstate transportation corridors.

Examples of critical facilities for government and commerce in West Sacramento that would be affected by a flood event are the CHP Academy, regional distribution centers for the U.S. Postal Service and United Parcel Service, Raley Field, offices for the California Department of General Services and California State Teachers' Retirement System, the Port of West Sacramento, wastewater treatment facilities, Interstate 80, US 50, and numerous other government and commercial buildings and infrastructure.

4.3.1.4 CHP Academy Flood Improvement Alternatives

4.3.1.4.1 CHP Academy Applicant Preferred Alternative—Slurry Cutoff Wall and Waterside Slope Flattening

The CHP Academy APA consists of a combination of a slurry cutoff wall and slope flattening. To address under- and through-seepage concerns, a slurry cutoff wall varying in depths from 25 to 80 feet deep below the degrade elevation is proposed. The slope flattening treatment is proposed to alleviate geometry deficiencies. The waterside slope would be flattened to a 2.5:1 slope shifting the levee prism 10 to 20 feet landward (pending USACE approval based on engineering analysis to support a slope steeper than 3:1). Improvements constructed on the landside of the levee may consist of reconstructing the landside stability berm, interior drain and toe drain system. All alternatives would occur within the construction limits which are bounded on the landside by the CHP Academy property fence. The 1,200 linear feet of concrete cap on the waterside slope adjacent

to the weir would be demolished and removed before slurry cutoff wall and slope flattening construction and replaced after construction is complete. The staging area for equipment is an approximate 6.50-acre area within the bypass and adjacent to the levee. The southern boundary of the construction limit of work is the CHP Academy fence line; therefore, the CHP Academy property would not be affected by construction for the CHP Academy APA. The levee treatments and phases of construction are described in more detail below. The phase of construction, necessary equipment, and estimated duration for each phase are presented at the end of the discussion in Table 4-3.

Treatments

Slurry Cutoff Wall

An 80-foot-deep by 3-foot-wide slurry cutoff wall is proposed to be constructed from station 18+00 to station 52+00 and a 25-foot-deep by 3-foot-wide slurry cutoff wall is proposed to be constructed from station 52+00 to station 61+75 (Figure 4-1). The levee would be degraded and then the conventional slot trench method would be used to construct the wall. During slurry cutoff wall construction, one crew would be able to construct approximately 40 to 50 linear feet of slurry cutoff wall in an 8-hour shift. Mixing areas would be located at the staging area. The mixing area would be used to prepare the soil-bentonite mixture and supply bentonite-water slurry. The mixing area would be contained by installing erosion control materials in accordance with the Stormwater Pollution Prevention Plan (SWPPP) to avoid dispersal of inadvertently spilled mixing materials. Vertical clearance of about 40 feet would be needed for the excavator boom. Horizontal clearance of about 30 feet beyond the levee crest may be required for excavator swing when loading dump trucks. Dump truck trips would haul material between the excavator and the mixing area along the levee.

Slope Flattening

To flatten the waterside slope, the waterside slope would be trimmed and reshaped to a 2.5:1 slope the full length of the site. After slope flattening, the levee crown would be a minimum of 20 feet wide, and the levee prism would shift 10 to 20 feet landward. The existing waterside hingepoint would move landward and the waterside toe would remain in the same place. On the landside, an interior drain and sub-surface drainage canal presently run the length of the Sacramento Bypass Levee. The drainage canal runs along the landside berm toe and captures water that daylights from an existing interior drain. This drainage canal flows to the westernmost end of the Sacramento Bypass Levee to a pump station that pumps the water over the levee into the bypass. Improvements constructed on the landside of the levee may consist of reconstructing the landside stability berm, interior drain, and toe drain system. All alternatives would occur within the construction limits which are bounded on the landside by the CHP Academy property fence. No permanent fill of wetlands or waters of the United States is proposed. Embankment fill material excavated to flatten the slope would be transported to the staging area and, if suitable, reused.

Construction Details

Construction Staging

As depicted on Figure 4-1, an approximate 6.50-acre area within the bypass would be used for staging construction activities and provide space to house construction equipment and materials before and during construction activities. There is an existing elderberry shrub 20 feet from the

staging area. Staging activities would be restricted to a minimum of 20 feet away from the shrub and the shrub would not be disturbed by construction or staging activities.

Temporary Facilities and Access Provisions

To facilitate project construction, earthen ramps would be constructed to allow equipment in the bypass to facilitate access between the levee crown and staging area. The earthen ramps would be removed when construction is complete.

Protection of Biological Resources

WSAFCA representatives met with representatives of USFWS and CDFG at the CHP Academy EIP site in December 2009 to discuss acceptable measures for the protection of special status species. During this coordination meeting, measures to protect VELB, giant garter snake, and Swainson's hawk, were agreed upon and are included as part of the CHP Academy EIP. Those measures include protective K-rail fencing, orange construction fencing, exclusion fencing, and on-site biological monitors (Figure 4-2). See the Vegetation and Wetlands and Wildlife sections (4.10 and 4.12) for descriptions of land cover types where these species may exist and of the potential effects of this project on these species. Protective measures that will be implemented as part of the CHP Academy EIP for each of the species are as follows:

Valley Elderberry Longhorn Beetle

Two elderberry shrubs occur in the study area. One elderberry shrub (EB 146) occurs in the northwestern area of the project site within the Sacramento Bypass, adjacent to an existing maintenance road (approximately 30 feet wide) used for levee maintenance and patrolling activities. Grading activities are proposed to occur down the levee slope to the toe of the levee, approximately 30 feet from the shrub. Hauling activities may occur adjacent to the shrub, but outside the dripline. The other shrub (EB 177) is in the southeast corner of the project area approximately 15 feet from the proposed construction limits, beneath a large oak tree. Neither shrub is expected to be removed or disturbed. Elderberry shrub survey results are shown in Section 4.10, Wildlife, Table 4.12-3, and the locations of these shrubs are shown in Section 4.10, Wildlife, Figure 4.12-1.

The following measures will be implemented as part of the CHP Academy EIP to avoid and minimize effects on VELB:

- Before ground disturbance, all construction personnel will participate in a USFWS-approved worker environmental awareness program. A qualified biologist approved by the USFWS will inform all construction personnel about the life history of VELB and the importance of its host shrub, the elderberry. Proof of this instruction will be submitted to the USFWS.
- For shrub EB 146, 100 feet of concrete barriers (K-rails) will be installed along the maintenance road in front of the shrub (50 feet west and 50 feet east of the shrub). Beyond the concrete barrier, temporary orange construction fencing (4-foot-high commercial- quality woven polypropylene) will be installed to completely surround the shrub and form a 20-foot construction buffer on the north, east, and west sides of the shrub. For shrub EB 177, a 20-foot temporary orange construction fence buffer will be installed around the shrub and any adjacent vegetation that requires protection (see Figure 4-2). Within buffer areas, signs will be posted along fencing for the duration of construction. The signs will contain the following information:

This area is habitat of the valley elderberry longhorn beetle, a threatened species, and must not be disturbed. This species is protected by the Endangered Species Act of 1973, as amended. Violators are subject to prosecution, fines, and imprisonment.

- Buffer area fences around elderberry shrubs/clusters will be inspected weekly by a qualified biologist during ground-disturbing activities and monthly after ground-disturbing activities until project construction is complete or until the fences are removed, as approved by the biological monitor and the resident engineer. The biological monitor will be responsible for ensuring that the contractor maintains the buffer area fences around elderberry shrubs throughout construction. Biological inspection reports will be provided to the project lead and USFWS.
- WSAFCA will ensure that the project site will be watered down as necessary to prevent dust from becoming airborne and accumulating on elderberry shrubs in and adjacent to a project site.

Giant Garter Snake

Giant garter snakes have the potential to use aquatic habitat in the study area, including depressional wetland and open water areas. Upland areas adjacent to these aquatic habitats could also be used by giant garter snakes for basking, cover, and refuge areas.

WSAFCA will implement the following measures to avoid and minimize effects on giant garter snake and their habitat:

- Before ground disturbance, all construction personnel will participate in a USFWS-approved worker environmental awareness program. A qualified biologist approved by the USFWS will inform all construction personnel about the life history of giant garter snakes and the importance of both aquatic and upland habitat areas. Proof of this instruction will be submitted to the USFWS.
- To reduce the likelihood of snakes entering these areas during construction activities, WSAFCA has agreed to install exclusion fencing along the depressional wetland and open water areas (areas within 200 feet of suitable habitat) (see Figure 4-2). The exclusion fencing will be installed during the active period for giant garter snakes (May 1 to October 1) to reduce the potential for direct loss of the species during this activity. The fencing will consist of 3- to 4-foot-tall erosion fencing buried at least 6 to 8 inches below ground level. The fencing will ensure that giant garter snakes are excluded from the construction area and that suitable upland and aquatic habitat is protected throughout construction. To ensure that construction equipment and personnel do not affect aquatic habitat for giant garter snake outside the construction corridor, a combination of K-rail fencing and orange barrier fencing will be erected (in addition to the exclusion fencing) to clearly define the aquatic habitat to be avoided.
- A USFWS-approved biologist will conduct a preconstruction survey in suitable habitat no more than 24 hours before construction. Prior to construction each morning, the biologist will survey for the presence of any giant garter snakes and inspect exclusion and orange barrier fencing to ensure they are both in good working order. The project area will be re-inspected whenever a lapse in construction activity of 2 weeks or more has occurred. If a snake is encountered during construction, activities will cease until appropriate corrective measures have been completed or it has been determined that the snake will not be harmed.

N

0 250 500 1,000 Feet

Figure 4-2
CHP Academy EIP
Protection Fencing Map

- Vegetation clearing within 200 feet of the banks of potential giant garter snake aquatic habitat will be limited to the minimum area necessary. Avoided giant garter snake habitat within or adjacent to the project area will be flagged and designated as an environmentally sensitive area, to be avoided by all construction personnel.
- The movement of heavy equipment within 200 feet of the banks of potential giant garter snake aquatic habitat will be confined to designated haul routes to minimize habitat disturbance.

Swainson's Hawk

Swainson's hawks are known to nest in and adjacent to the study area, and project construction within this reach could affect Swainson's hawk, either directly or through habitat modification.

To avoid and minimize effects on Swainson's hawk, WSAFCA representatives coordinated with DFG representatives during a field visit in December 2009, and agreed to implement the following measures as part of the CHP Academy EIP:

- Before ground disturbance, all construction personnel will participate in a CDFG-approved worker environmental awareness program. A qualified biologist will inform all construction personnel about the life history of Swainson's hawk and the importance of nest sites and foraging habitat.
- A breeding season survey for nesting birds will be conducted for all trees and shrubs that will be removed or disturbed which are located within 500 feet (0.5 mile for Swainson's hawk) of construction activities, including grading. Swainson's hawk surveys will be completed during at least two of the following survey periods; January 1 to March 20, March 20 to April 5, April 5 to April 20, and June 10 to July 30 with no fewer than three surveys completed in at least two survey periods, and with at least one of these surveys occurring immediately prior to project initiation (Swainson's Hawk Technical Advisory Committee 2000). Other migratory bird nest surveys can be conducted concurrent with Swainson's hawk surveys with at least one survey to be conducted no more than 48 hours from the initiation of project activities to confirm the absence of nesting. If the biologist determines that the area surveyed does not contain any active nests, construction activities, including removal or pruning of trees and shrubs, can commence.
- If active nests are found, WSAFCA will maintain a 0.25-mile buffer between construction activities and the active nest(s). In addition, a qualified biologist will be present on-site during construction activities to ensure the buffer distance is adequate and the birds are not showing any signs of stress. If signs of stress that may cause nest abandonment are noted, construction activities will cease until a qualified biologist determines that fledglings have left an active nest.

Demolition and Vegetation Removal

Demolition and vegetation removal would be performed for levee improvement construction and to comply with USACE vegetation guidance and CVFPB encroachment regulations requiring a vegetation-free zone. Vegetation clearing activities would consist of removing the larger woody vegetation such as trees and shrubs. Grubbing activities consist of removing roots and stripping activities consist of excavating approximately one foot of organic material from the levee surface. A stand of trees on the waterside of the levee (in the bypass), approximately 20 feet from the levee toe, would be pruned for construction equipment clearance. Demolition activities include demolition and removal of the 1,200-linear-foot-long concrete liner along the waterside slope of the levee

(adjacent to the weir). The concrete debris would be hauled off site to an appropriate disposal location within 20 miles of the site.

Levee Degradation

Prior to slurry wall and slope flattening construction, approximately two-thirds of the levee crown would be degraded to provide a 60- to 80-foot working platform. Approximately 89,000 cubic yards would be degraded or excavated and hauled from the project site and disposed of at a permitted site within 20 miles of the project site. Following completion of the slurry cutoff wall, approximately 79,600 cubic yards of suitable levee construction embankment fill material may be transported from a permitted source approximately 10 miles away from the project site to restore the levee crown to its original elevation.

Note: Concurrent with the writing of this EIS/EIR, DWR was undertaking a sediment cleanout project of the Sacramento Bypass. The spoils from the sediment cleanout project are to be cast onto the landside berm of the CHP Academy EIP site. The spoils would be removed as part of the CHP Academy EIP to construct the necessary improvements and reused on site as berm material or to increase the overall levee prism. While the final quantities are not known, the material-handling operations are considered consistent with the type and magnitude of effects as described for the CHP Academy EIP; and, therefore, do not modify the findings or mitigation required.

Materials Reuse and Importation

Materials imported to the project site would include water, bentonite, cement, incidental construction support materials, aggregate base rock, hydroseed, and about 79,600 cubic yards of embankment fill material to replace poor levee material. Embankment fill material excavated to construct levee improvements would be evaluated for reuse. Embankment fill material deemed suitable for reuse would be used to rebuild the levee. Embankment fill material of poor quality would be hauled off site to a permitted disposal site within 20 miles of the project site.

Post-Construction Operation and Maintenance

The only permanent facility associated with the project would be the new levee footprint itself. After construction completion, the levee and staging areas and levee slopes would be hydroseeded for erosion protection and to prevent colonization of exotic vegetation. Access roads adjacent to the levee would be restored to preexisting conditions.

Typical O&M activities (as described under the Program Description) would include the following actions:

- vegetation maintenance up to four times a year by mowing or applying herbicide;
- slope reconditioning up to once a year by dozing and track-walking the levee slopes;
- patrol road reconditioning up to once a year by placing, spreading, grading, and compacting aggregate base or substrate; and
- visual inspection as needed by driving on and observing from the patrol road.

Construction Schedule

The CHP Academy APA would be constructed during the 2011 construction season (typically April 15 to November 1). The project is expected to be completed within 130 days. Table 4-3 shows specific durations and equipment required for each phase of construction.

Constraints, which may include contract award delays due to permitting, early or late season rain, the presence of nesting raptors, and equipment shortages, have the potential to suspend the construction of the project before the start of the flood season (November 1) in 2011. The CHP Academy APA construction contract would allow the contractor to construct on a 24-hours-per-day/7-days-per-week (24/7) work schedule to complete the construction of the improvements before the flood season in order to manage the risk of delay due to the constraints described above. The construction schedule described in the section below lists both the standard 10-hour-per-day/5-days-per-week work schedule and the 24/7 condensed work schedule. Either of these schedules may be used for the project.

Table 4-3. CHP Academy APA: Construction Schedule Options

Phase of Flood Improvements Construction	Required Equipment	Standard Duration (Days)	24/7 Duration (Days)
Mobilization	N/A	1	0.4
Clearing and grubbing	A bulldozer, dump trucks, and an excavator	9	3.75
Concrete removal	A loader, dump trucks, and excavators	7	3
Levee degrade	A bulldozer, dump trucks, and an excavator	26	11
Slope flattening	A bulldozer, dump trucks, and an excavator	5	2
Slurry wall construction	Bulldozers, a long reach track hoe, a loader, and rough terrain forklift, 3-4 dump trucks, excavator, compactor, maintainer and water truck	29	12
Embankment fill placement	Bulldozers, dump trucks, an excavator, a compactor, a maintainer, and a water truck	27	11.25
Concrete placement	Concrete trucks and a crane	24	10
Roadway reconstruction	Dump trucks, a skip loader, a blade, a sheepsfoot compactor, a distributor, an asphalt paver, a pneumatic compactor, and a roller compactor	2	.8
Demobilization	N/A	2	0.8
Total Days:		**130**	**55**

4.3.1.4.2 CHP Academy Alternative B—Stability Berm, Interior Drain, and Relief Wells

The treatments proposed under Alternative B at the CHP Academy EIP (CHP Academy Alternative B) consist of the construction of an interior drain within the levee, a stability berm on the landside of the levee, and the installation of relief wells (Figure 4-1). The interior drain and relief wells would alleviate seepage, and the stability berm would address geometry deficiencies. The first 1,200 linear feet of concrete cap on the waterside slope adjacent to the weir would be demolished, removed, and hauled off site for disposal before construction and replaced after construction. The staging area for

equipment would be located in an approximately 6.5-acre area adjacent to the Sacramento Bypass Levee within the bypass. The southern boundary of the construction limit of work is the CHP Academy fence line; therefore, the CHP Academy property would not be affected by construction for the CHP Academy APA. The treatments and phases of construction are described in more detail below. The phase of construction, equipment necessary and estimated duration for each phase are presented at the end of the discussion in Table 4-4.

Treatments

Stability Berm and Interior Drain

A reinforced stability berm would replace the existing landside stability berm. The existing stability berm would be excavated the entire length of the reach within the project area. Approximately 11,000 cubic yards would be degraded and hauled from the project site and disposed of at a permitted site within 20 miles of the project. Construction of the interior drain would occur after excavation and removal of the existing stability berm. A 1.5-foot-thick base layer of drain rock would be placed at the levee toe, extending roughly 15 feet into the levee foundation. An additional drain layer, approximately 1.5 feet thick, would extend upward and into the core of the levee at a 2:1 slope from the end of the base layer to the approximate elevation of the design flood. A layer of geotextile material would then be placed over the additional drain layer and imported embankment fill material would be placed on top of the drain layer to rebuild the levee.

After completion of the interior drain, the stability berm would be rebuilt. The height of the stability berm would be two-thirds the height of the levee and extend the entire length of the project site. Dump trucks would transport 7,000 cubic yards of embankment fill material to the stability berm site. Motor graders would spread the material evenly and a sheepsfoot roller would compact the material. The footprint of the new stability berm would be the same as the existing landside stability berm.

Currently, a drainage canal runs along the landside berm toe and captures water that daylights from an existing interior drain. This drainage canal flows to the westernmost end of the Sacramento Bypass Levee to a pump station that pumps the water over the levee into the bypass. This drainage canal may be temporarily affected by construction but would be rebuilt to its original specification after interior drain installation. The drainage canal would continue to capture seeping water and direct it to the pump station.

Relief Wells

After the construction of the stability berm and interior drain, relief wells would be constructed 15 feet from the berm toe. Relief wells would be used to address under-seepage.

Approximately 20 to 40 relief wells would be constructed using soil-boring equipment to drill a hole vertically through the fine-grained blanket layer (sand) into the coarse-grained aquifer layer (gravel) beneath. Pipe casings and gravel/sand filters would be installed to allow water to freely flow to the ground surface, relieving the pressure beneath the clay blanket without transporting fine materials to the surface, which can undermine the levee foundation. The water would collect in a v-ditch and flow to the existing drainage ditch to be pumped back into the bypass by the existing pump station at the westernmost end of the Sacramento Bypass Levee.

Relief wells would be spaced in 50- to 100-foot intervals, dependent upon the amount of under-seepage, and extend to depths of 100 to 120 feet. Areas for relief well construction would be cleared,

grubbed, and stripped. During relief well construction, a typical well-drilling rig is used to drill to the required depth and construct the well (including well casing, gravel pack material, and well seal) beneath the ground surface. The drill rig likely would be an all-terrain, track-mounted rig that could access the well locations from the levee toe.

Construction Details

Construction Staging

As depicted on Figure 4-1, an approximately 6.5 -acre area within the bypass would be used for staging construction activities and to provide space to house construction equipment and materials before and during construction activities. There is an existing elderberry shrub 20 feet from the staging area. Staging and construction activities would remain 20 feet away from the elderberry shrub and it would not be disturbed by construction or staging activities.

Temporary Facilities and Access Provisions

To facilitate project construction, earthen ramps would be constructed to allow equipment in the bypass to facilitate access between the levee crown and staging area. The earthen ramps would be removed when construction is complete.

Demolition and Vegetation Removal

Demolition and vegetation removal would be performed for levee improvement construction and to comply with USACE vegetation guidance and CVFPB encroachment regulations requiring a vegetation-free zone. Clearing activities would consist of removing the larger vegetation such as trees and shrubs. Grubbing activities would consist of removing roots and stripping activities would consist of excavating approximately a foot of organic material from the levee surface. A stand of trees on the waterside of the levee, approximately 20 feet from the levee toe, would be pruned for construction access. This phase of construction would also include demolition and removal of the 1,200-linear-foot-long concrete liner along the waterside slope of the levee adjacent to the weir. The concrete debris would be hauled off site to an appropriate disposal location.

Materials Reuse and Importation

Materials imported to the project site would include water, drain rock, geotextile material, aggregate base rock, well casing, sand and gravel, concrete, a drain pipe, hydroseed, and about 7,000 cubic yards of embankment fill material to replace poor levee material. Embankment fill material excavated to construct levee improvements would be evaluated to determine if it is suitable for reuse. Any of the embankment fill material deemed suitable for reuse would be used to rebuild the levee. Embankment fill material of poor quality would be hauled to a permitted disposal site.

Note: Concurrent with the writing of this EIS/EIR, DWR was undertaking a sediment cleanout project of the Sacramento Bypass. The spoils from the sediment cleanout project are to be cast onto the landside berm of the CHP Academy EIP site. The spoils would be removed as part of the CHP Academy EIP to construct the necessary improvements and reused on site as berm material or to increase the overall levee prism. While the final quantities are not known, the material-handling operations are considered consistent with the type and magnitude of effects as described for the CHP Academy EIP; and, therefore, do not modify the findings or mitigation required.

Post-Construction Operation and Maintenance

After construction of the seepage berm, interior drain, and relief wells, the staging areas and levee slopes would be hydroseeded for erosion protection and to prevent colonization of exotic vegetation. Access roads adjacent to the levee would be restored to preexisting conditions.

The interior drain, stability berm, and relief wells and associated lateral drains would be the permanent facilities resulting from the project. Inspection of the relief wells would be required at least annually, and observation of flow from the wells would be required during high river stages. The wells would be test-pumped every 2 years, and the discharge water from those tests would be trucked off site to a central disposal, if necessary. The drainage ditch would be maintained to allow free flow of water. Piezometers, also called monitoring wells, would be installed between each relief well to allow monitoring of groundwater levels to ensure the wells are relieving the pressure within the aquifer.

Construction Schedule

The goal of the project is to complete the CHP Academy Alternative B in 2011. The project is expected to be completed within 67 days. All flood improvement construction and staging would take place during the typical construction season (April 15 to November 1). Table 4-4 shows specific durations and equipment required for each phase of construction.

Constraints, which may include contract award delays due to permitting, early or late season rain, the presence of nesting raptors, and equipment shortages, have the potential to suspend the construction of the project before the start of the flood season (November 1) in 2011. The CHP Academy Alternative B construction contract would allow the contractor to construct on a 24-hours-per-day/7-days-per-week (24/7) work schedule to complete the construction of the improvements before the flood season in order to manage the risk of delay due to the constraints described above. The construction schedule described in the section below lists both the standard 10-hour-per-day/5-days-per-week work schedule and the 24/7 condensed work schedule. Either of these schedules may be used for the project.

Table 4-4. CHP Academy Alternative B: Construction Schedule Options

Phase of Flood Improvements Construction	Required Equipment	Standard Duration (Days)	24/7 Duration (Days)
Mobilization	N/A	2	0.8
Clearing and grubbing	A bulldozer, dump trucks, and an excavator	4	1.6
Excavate stability berm	A loader, dump trucks, and excavators	5	2
Install stability berm and interior drain system	Bulldozers, dump trucks, an excavator, a sheep foot compactor, a maintainer, and a water truck	31	13
Install relief wells	Drill rig and crane	22	9

4.3.1.5 CHP Academy Recreation Improvements

The CHP Academy recreation improvements would consist of a paved trail on the levee crown the entire length of the site (6,500 feet). The paved trail would be designed in compliance with USACE and CVFPB standards. Details of the recreation program improvement components are described below.

4.3.1.5.1 Paved Bike Trail

- The trail alignment is proposed atop the existing aggregate base access roads currently used for flood control maintenance and operations (Figure 4-1).
- The paved bike trail would be approximately 12 feet wide with a 2-foot-wide compacted aggregate base shoulder on either side of the trail to match the grade. Asphalt within the 12-foot-wide section would be 2 to 8 inches thick with a 4- to 8-inch-thick base.

4.3.1.5.2 Access and Signage

- Removable access controls (bollards) would be installed at the entrance of the Sacramento Bypass Levee.
- Permanent safety signs would be installed at select trail access points and at periodic intervals along the trails to inform users that the trail serves as a levee maintenance road and to instruct them to watch for patrolling vehicles. These signs would also inform users that portions of the trail are subject to flooding and that trail damage and related safety hazards could occur during the flooding season.

4.3.1.5.3 Construction Details

Construction staging and parking would be limited to areas that been selected for construction staging for the flood improvements. All recreation improvement construction and staging would

take place during the typical construction season (April 15 to November 1). Construction of the bicycle/pedestrian trails would consist of compacting, paving, and striping the existing graded levee top. Recreation improvement construction is expected to be completed within 25 days.

Grasses and other native vegetation approved by USACE and CVFPB would be planted after project construction to stabilize soils and reduce runoff from temporary disturbance areas.

Table 4-5 lists the types of construction equipment that may be used to construct the recreation improvements of the CHP Academy EIP.

Table 4-5. CHP Academy EIP Recreation Improvements

Phase of Recreation Improvement Construction	Required Equipment	Standard Duration (Days)
Mobilization	N/A	2
Grading	Scraper, wheel loader, motor grader, dump truck, steel wheel loader, and water truck	8
Install pathways and signs	Dump truck, asphalt paver, asphalt sealer, striping truck, small front loader, skid steer loader and small roller	12
Demobilization	N/A	3
Total Days:		**25**

4.3.1.5.4 Operation and Maintenance

The bikeway and all related facilities would be maintained by the City. The City would be responsible for checking trails and conducting trail repairs at the end of the flood season and as needed. Maintenance of the bike trail would include sweeping, pavement repair, removal of obstacles, mowing and trimming, periodic asphalt overlays, and repair of associated facilities. Environmental commitments for levee improvements at this EIP site, as well as for the entire WSLIP program, are discussed in detail in Section 2.9 of this EIS/EIR.

4.3.2 Environmental Commitments

As presented in Chapter 2, environmental commitments are measures incorporated as part of the project description, meaning they are proposed as elements of the proposed action and are to be considered in conducting the environmental analysis and determining effects and findings. To avoid and minimize construction-related effects, WSAFCA would implement the following environmental commitments at the program and project levels to reduce or offset short-term, construction-related effects. Measures have been developed for each of the topics below, to be applied in the program- and project-level resource analyses.

- Raptors
- USACE Levee Vegetation Guidance
- Protected Trees and Riparian Trees
- Avoid and Minimize the Spread or Introduction of Invasive Plant Species
- Stormwater Pollution Prevention Plan

- Temporary Visual Barriers between Construction Zones and Residences
- Noise-Reducing Construction Practices
- Temporary Resident Relocation, Property Acquisition, and Compensation for Loss of Business
- Traffic Control and Road Maintenance Plan
- Coordination to Ensure Minimal Overlap in Disturbance to Traffic during WSLIP Construction
- Coordination of Construction Periods with Railroad Service Officials
- Coordination of Construction Periods with CHP
- Notification of Construction Area Closure
- Minimization of Construction-Related Effects on Navigation
- Bentonite Slurry Spill Contingency Plan
- Spill Prevention, Control, and Counter-Measure Plan
- Implementation of Measures to Maintain Surface Water Quality and Groundwater Quality
- Monitoring of Turbidity in Adjacent Water Bodies
- Soil Supply Protection Measures

Section 4.4

Flood Control and Geomorphic Conditions—CHP Academy Early Implementation Project

4.4.1 Affected Environment

This section describes the affected environment for hydrologic, hydraulic, geomorphic, and flood control issues in the CHP Academy EIP project area, including regulatory and environmental setting.

4.4.1.1 Regulatory Setting

4.4.1.1.1 Federal

The following Federal policies related to hydrologic, hydraulic, geomorphic, and flood control issues may apply to implementation of the CHP Academy EIP. Please see Section 3.2.3.3, Regulatory Setting, for a more complete description of each policy.

- National Flood Insurance Program
- U.S. Army Corps of Engineers Levee Design Criteria
- Executive Order 11988 (Floodplain Management)
- Section 401 of the Clean Water Act and State Regulations in Title 23 California Code of Regulations
- Code of Federal Regulations, Title 40, Part 131, Water Quality Standards
- Section 408
- Public Law 84-99 Delta Specific Standard

4.4.1.1.2 State

The following state policies related to hydrologic, hydraulic, geomorphic, and flood control issues may apply to implementation of the CHP Academy EIP. Please see Section 3.2.3.3, Regulatory Setting, for a more complete description of each policy.

- Central Valley Flood Protection Board
- Delta Protection Act of 1992
- Safe, Clean, Reliable Water Supply Act

4.4.1.1.3 Local

The following local policies and agencies related to hydrologic, hydraulic, geomorphic, and flood control issues may apply to implementation of the CHP Academy EIP. Please see Section 3.2.3.3, Regulatory Setting, for a more complete description of each policy.

- *Health and Safety Element of the Draft 2030 Countywide General Plan for Yolo County*

- *Health and Safety Section of the City of West Sacramento General Plan, Policy Document* (City of West Sacramento 1990)
- West Sacramento Area Flood Control Agency

4.4.1.2 Environmental Setting

This site incorporates the entire 6,500 feet of the southern Sacramento Bypass Levee. The CHP Academy EIP site exhibits through-seepage and geometry deficiencies. Under-seepage and stability deficiencies are also present in smaller pockets over the site. This section generally discusses the environmental setting related to hydrologic, hydraulic, geomorphic, and flood control issues in the larger CHP Academy EIP project area (Figure 3.2-1). For more detailed information about this resource, including climate, regional hydrology and geomorphic conditions, levee stability and levee height evaluations, see Section 3.2.2.2, Environmental Setting, of the program analysis.

Yolo and Sacramento Bypass Reaches (Yolo Bypass Levee, Sacramento Bypass Levee, and Deep Water Ship Channel West Levee—Reaches 5, 6, and 9C)

Flows in the Yolo Bypass come from several different sources. Floodflows from Sutter Bypass and the Sacramento River enter the Yolo Bypass over the Fremont Weir when the stage in the Sacramento River reaches 29.7 feet in the National Geodetic Vertical Datum of 1929 (NGVD29). Water also enters the Yolo Bypass from the west side tributaries—Knights Landing Ridge Cut, Cache Creek (Cobble Weir), Willow Slough Bypass, and Putah Creek—and from the Sacramento Weir. The gates of the Sacramento Weir are opened when stages exceed 27.5 feet (NGVD29) at the I Street Bridge: the weir operates infrequently. Various documents describe the relative importance of these sources of floodflows (Yolo Bypass Working Group 2001; Natural Heritage Institute 2003).

DWR has maintained a gage at Lisbon Weir, along the Yolo Bypass Levee, since 1935. Water levels at this gage are tidally influenced and fluctuate between 3 and 7 feet stage (USACE datum) or between 0.5 and 4.5 feet NGVD 29, at low water. Flood stage at the gage is 11.5 feet (9 feet NGVD 29); above this elevation water is no longer contained in the Toe Drain and the Yolo Bypass starts to inundate. The Yolo Bypass floods about 3 out of 5 years, on average, and the annual duration of flooding ranges from zero to 135 days.

The maximum stage recorded at the Lisbon Weir was 24.9 feet NGVD 29 in February 1986. The maximum stage in January 1997, 24.6 feet, was slightly lower than in 1986, but the maxima in these two years are several feet higher than in the other years of record (Jones & Stokes 2006). Water surface elevations in these years were only 2 to 3 feet below the top of the Yolo Bypass levee (U.S. Army Corps of Engineers 2006). Since 1997, USACE has raised levee elevations along the upper portion of the Yolo Bypass Reach and in the Sacramento Bypass by up to 5 feet.

Based on the DWSC West Levee sections in Appendix D of NHC (2007a), a typical elevation for the berm on the Yolo Bypass side of the levee near the Lisbon gage is 15 to 20 feet NGVD 1929. Based on the mean daily water surface elevation duration curve for Lisbon gage in NHC (2007a), stage exceeds this elevation only 2 or 3% of the time, indicating that high water levels that result in wave attack on the levee occur only infrequently.

MBK Engineers provided average cross-sectional velocities in the Yolo Bypass from their UNET model. These velocities varied from 2 to 4 feet/second despite the large cross-sectional area in the bypass. Velocity data at the Lisbon Gage, which is close to the levee, show maximum velocities of about 2.5 feet/second. Velocities vary considerably across the sections and may be higher where

flows accelerate around obstacles, around bends, or where the section narrows. (Northwest Hydraulic Consultants 2007a.)

Yolo and Sacramento Bypass Reaches (Yolo Bypass Levee, Sacramento Bypass Levee, and Deep Water Ship Channel West Levee—Reaches 5, 6, and 9C)

Levee and Bank Geometry

Sacramento and Yolo Bypass Levees (Reaches 5 and 6)

The levees in the Sacramento and Yolo Bypass are part of the original Federal project levee built in the early 20th century. Kleinfelder (2007) indicates that this levee originally was constructed by clamshell dredge with the local flood basin deposits. Table 4.4-1 summarizes construction undertaken to upgrade the levees in the mid-20th century, as shown in The Supplement to Standard Operation and Maintenance Manual for the Sacramento River Flood Control Project Unit No.116, from 1955.

The Yolo and Sacramento Bypass levees also have been upgraded since the 1950s, most recently in 1998 and 1999 by USACE when the levee crests were raised a maximum of 5 feet, damage from the 1997 flood repaired, and rock revetment added for wave and velocity erosion protection (Northwest Hydraulic Consultants Inc. 2007a). The revetment slumped in February 1998 and again at two sites near the Interstate 80 Bridge in January 2006. The revetment failures appear to result from slumping of saturated clays in the levee and foundation materials, resulting in failure of the revetment. Repairs of these failures are underway by DWR (Northwest Hydraulic Consultants Inc. 2007a). Levee soils are assumed to be similar to those along the DWSC West Levee (Kleinfelder 2007)[1].

Table 4.4-1. Historic Construction to Bring Levees Built by Local Interests to Project Standards

Job Order	Date	Location	Description

Source: Northwest Hydraulic Consultants 2007a.

Existing Bank Protection

There is no formal inventory of bank protection works along the Yolo and Sacramento Bypass levees; however, most of both levees are protected by revetment. As discussed above, revetment was placed on the upper end of the Yolo Bypass east levee and the south Sacramento Bypass levee in the late 1990s. Revetment covers about 540 feet around the pump station outlet in the Sacramento

[1] NHC had not received or reviewed a geotechnical data report for these levee sections since submittal of NHC 2007a.

Bypass, consisting of quarry rock with a median size of about 9 inches and a maximum size of 12 inches. The portion of the Sacramento Bypass Levee directly below the Sacramento Weir is lined with concrete.

Structures

An outfall from a pump station is located on the Sacramento Bypass levee at Station 1+50. The outfall is protected with rock riprap, and erosion was not observed the outfall location.

4.4.1.2.2 Levee Deficiencies

Section 4 of HDR, Inc. (2008a) includes the geotechnical assessment of the existing levees with regard to seepage, slope stability, and seismic vulnerabilities[2]. The information provided in HDR, Inc. (2008a) is derived from two reports: *West Sacramento Levee System Problem Identification and Alternative Analysis: Volume 1—Geotechnical Problem Identification Solano and Yolo Counties, California* (Kleinfelder 2007), and *Phase 1 Geotechnical Evaluation Report (P1GER) West Sacramento* Region (URS 2007).

Data collection included 323 borings drilled with standard penetration tests and soundings made using cone penetration test equipment along the levees within the basin. Approximate stationing endpoints have been determined by URS (2007) and Kleinfelder (2007) based on similar soil characteristics within the endpoints. Deficiencies identified within the approximate stationing endpoints do not indicate the entire stretch of levee contains said deficiency; rather, a deficiency has been identified within the endpoints (HDR 2008a).

Levee Seepage Analysis

Engineering analysis evaluating levee seepage along the Sacramento Bypass Levees has been performed by URS (2007), and the findings were presented in their report titled *Phase 1 Geotechnical Evaluation Report (P1GER) West Sacramento Region* (URS 2007). URS (2007) performed their seepage analysis using water surface elevations that are different from the water surface elevations used in this chapter as determined by MBK Engineers (2007) and assumed a no-flow boundary at the center of the river (HDR 2008a).

Table 4.4-2 shows the seepage summary of the Sacramento Bypass Levees as completed by URS (2007). Exit gradients of 0.5 or greater for under-seepage require mitigation according to the USACE, and areas where through-seepage has been observed or projected based on soil conditions require mitigation.

Kleinfelder (2007) performed the engineering analysis evaluating levee seepage along the Sacramento Bypass Levees and presented their findings in a report titled *West Sacramento Levee System Problem Identification and Alternative Analysis: Volume 1—Geotechnical Problem Identification Solano and Yolo Counties, California* (Kleinfelder 2007). Kleinfelder performed their analysis using the water surface elevations determined by MBK Engineers (2007) and assumed a total head boundary at the center of the river.

The seepage summaries for the Sacramento Bypass Levees as completed by Kleinfelder (2007) are shown in Table 4.4-3. Exit gradients of 0.5 or greater for under-seepage require mitigation according

[2] Seismic vulnerabilities are discussed in Chapter 6, Geology, Seismicity, Soils, and Mineral Resources.

to USACE, and areas where through-seepage has been observed or projected based on soil conditions require mitigation.

As described in the program section, the Sacramento River North Levee has a significant amount of under-seepage, whereas the other reaches (including the Sacramento Bypass) have much less extensive under-seepage problems. See Table 3.2-11 and Figure 4 of HDR, Inc. (2008b) for additional information.

Table 4.4-2. Seepage Summary

	Through-seepage		Under-seepage

Levee Slope Stability Assessment

URS (2007) completed an engineering evaluation of levee slope stability and the effect of rapid drawdown for the Sacramento Bypass Levee and presented their findings in the report titled *Phase 1 Geotechnical Evaluation Report (P1GER) West Sacramento Region* (URS 2007). As with the levee seepage analysis described above, URS (2007) used water surface elevations that are different from the water surface elevations determined by MBK Engineers (2007) in their analysis of slope stability[3]. Rapid drawdown calculations have been completed only for the 100-year event as recommended to URS by their Independent Consulting Board (HDR 2008a).

The slope stability results as completed by URS (2007) for the Sacramento Bypass Levees are shown in Table 4.4-4.

[3] Sections of the northern reaches have not been completed to date by URS; these sections will be completed in their final report projected to be issued at a later time.

Kleinfelder (2007) performed the engineering analysis evaluating levee slope stability and the effect of rapid drawdown along the Sacramento Bypass Levees and presented their findings in a report titled *West Sacramento Levee System Problem Identification and Alternative Analysis: Volume 1—Geotechnical Problem Identification Solano and Yolo Counties, California* (Kleinfelder 2007). Kleinfelder (2007) performed their analysis using the water surface elevations determined by MBK Engineers (2007).

The slope stability findings as completed by Kleinfelder (2007) are also shown in Table 4.4-4.

In brief, the Sacramento Bypass Levee has significant steady state stability deficiencies. See Table 3.2-11 and Figure 5 of HDR, Inc. (2008b) for additional information.

Table 4.4-4. Slope Stability Summary

	Steady State		Rapid Drawdown

Source: HDR, Inc. 2008a (a compilation of data from URS 2007 and Kleinfelder 2007).

Levee Geometry Evaluation

To evaluate the crown width and side slopes of the levees in the proposed program area, HDR, Inc. (2008a) generated topography data by means of Light Detection and Ranging (LIDAR) using the North American Vertical Datum of 1988 (NAVD 88).

In brief, most of the levees in the proposed program area, including the CHP Academy Site, have a geometry deficiency, and it is typically an over-steepened waterside slope that is the primary problem (HDR 2008b).

USACE requires that levees have a maximum steepness of 3:1 (H:V) waterside slopes and 3:1 (H:V) landside slope. The design criteria for the WSLIP conform with these requirements, unless site-specific conditions permit otherwise (and USACE approval is granted based on engineering analysis to support a slope steeper than 3:1). Crown widths for primary levees are to be a minimum of 20 feet. For the CHP Academy EIP, it is proposed that the waterside slope would be trimmed and reshaped to a 2.5:1 slope the full length of the site (pending USACE approval).

Refer to Appendix B in HDR, Inc. (2008a) for tables identifying sections of the levees that do not meet the design criterion. Appendix D in HDR, Inc. (2008a) contains LIDAR cross sections that have been used to evaluate levee geometry. Also refer to Figure 9 of HDR, Inc. (2008b), which shows the approximate locations where a geometry deficiency has been identified.

For a complete summary of levee deficiencies, refer to Chapter 1, Introduction.

4.4.1.2.3 Flooding

Levees along the Sacramento River and other waterways provide flood control for the city of West Sacramento and conveyance for waters from upstream to the Delta. High winter flows can stress

levees and berms. Longer flood durations can contribute to levee seepage and potentially structural levee failure. Flood water surface elevations also can exceed levee heights and cause overtopping and partially controlled flooding of the protected areas behind the levee. Overtopped levees may maintain structural integrity and would not be considered failed levees. However, the erosive forces that occur during overtopping eventually may cause a structural failure and uncontrolled flooding in the protected areas behind the levee. To maintain the integrity of the flood control system, locations with the potential for failure have been and are being identified and remedied.

MBK Engineers (2007, 2008a, and 2008b) has developed water surface profiles for use in this analysis. Their reports describe and present the results of a hydraulic analysis that was made to determine 1/100 and 1/200 AEP (commonly referred to as 100-year and 200-year) water surface elevations in the surrounding waterways, as well as the potential worst case flood depth for the South Cross Levee. The MBK version of the Comprehensive Study Sacramento River UNET model adopted for the Natomas Levee Improvement Program was used for this analysis. This adopted version is capable of modeling anticipated levee breaks or of allowing levee overtopping without failures. UNET is a one-dimensional unsteady open-channel flow model with the ability to simulate exchange of flow over levees with storage areas. The MBK UNET model results were a maximum composite of simulations made using hydrologic data for two storm centering scenarios: Sacramento River at latitude of Sacramento and Feather River at Shanghai Bend. In addition, the American River peak flow in the 100-year flood was 145,000 cfs, the current FEMA condition; in the 200-year flood the peak flow was 160,000 cfs, the expected future peak flow.

The resulting maximum water surface elevation profiles (for the 1/100 and 1/200 AEPs), the approximate tops of the levees, and the original 1957 Flood Control Project design floodplain for the Sacramento River and Sacramento Bypass are provided in Figures 3.2-4 through 3.2-7 and Table 3.2-13 of the program section.

The MBK UNET model indicates no levee overtopping will occur along the Sacramento River or the Sacramento Bypass for the 100-year or the 200-year design floodflows. More information is provided in MBK Engineers' *Hydraulics Report for the City of West Sacramento Levee Alternatives Analysis* (2007) and Northwest Hydraulic Consultant's *West Sacramento Levees System: Problem Identification Report, Erosion Assessment and Treatment Alternatives, Draft for Review* (2007a).

Refer to the program section for a description of flood elevations and levee height evaluation by reach and for a complete description of modeling of hydraulic effects.

4.4.1.2.4 Past Sea-Level Rise in the Program Area

MBK Engineers (2009b) applied the USACE sea-level rise guidance (U.S. Army Corps of Engineers 2009b) to the WSLIP in order to determine the effects of potential sea-level rise on the program area. Since the WSLIP sea-level rise analysis is in support of the pre-existing project design, many of the points in the USACE policy guidance do not apply, particularly those which refer to the comparison of project alternatives. The MBK Engineers (2009b) report uses the procedure for calculating sea-level rise that is identified in the USACE guidance, and applies that procedure to the proposed WSLIP design.

Analysis of Historic Mean Sea Level Change

As described in the MBK Engineers (2009b) report, the nearest tide station with sufficient period of record (40+ years recommended) is the NOAA station 9414290 at San Francisco, CA. Tidal records for this station have been maintained back to the 1850s.

The NOAA Center for Operational Oceanographic Products and Services (CO-OPS) has analyzed the historic mean sea level for this site, which has been shown to be increasing at a rate of 2.01mm/yr (California Climate Change Center 2009 as cited in MBK Engineers 2009b). Projections of future mean sea level change are discussed in the program section.

4.4.2 Environmental Consequences

This section describes the environmental consequences relating to hydrologic, hydraulic, geomorphic, and flood control issues for the proposed CHP Academy EIP. It describes the methods used to determine the effects of the project and lists the thresholds used to conclude whether an effect would be significant. These effects tier from the program analysis effects, described in Section 3.2.3.3, Effects and Mitigation Measures.

4.4.2.1 Assessment Methods

Assessment of environmental effects associated with hydrology, hydraulics, geomorphology, and flood control issues has been accomplished through the following means:

- MBK Engineers (2009) quantitative modeling of the WSLIP,
- MBK Engineers (2007) quantitative modeling of the effects of Sacramento River West Levee Setback at Oak Hall Bend,
- MBK Engineers (2005) hydraulic analysis of the effects of potential cumulative development in the Sacramento River corridor floodway between Verona and Courtland on flood stages and flows,
- an evaluation of existing conditions of proposed program area levees and projected incision and scour estimates in the adjacent waterways,
- qualitative assessments of sedimentation/scour potential based on existing Federal and state channel hydraulic design standards and guidelines, and
- determination of effects through professional judgment.

4.4.2.2 Determination of Effects

The criteria used for determining the significance of an effect on hydrology, hydraulics, geomorphology, and flood control are based on NEPA standards, Appendix G of the State CEQA Guidelines (Environmental Checklist) and standards of professional practice.

Effects on hydrologic or geomorphic conditions may be considered significant if implementation of an alternative would:

- substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, in a manner that would result in substantial erosion or siltation on or off site;
- substantially alter the existing drainage pattern of the site or area, including the alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in a manner that would result in flooding on or off site;
- place within a 100-year flood hazard area structures that would impede or redirect floodflows; or
- expose people or structures to a significant risk of loss, injury, or death involving flooding, including flooding as a result of the failure of a levee or dam.

Effects on flood control may be considered significant if implementation of an alternative would:

- significantly raise flood stage elevations;
- increase the frequency and duration of inundation of lands; or
- expose people or structures to a significant risk of loss, injury, or death involving flooding, including flooding as a result of the failure of a levee.

An effect on the levee system is considered significant if an alternative would substantially increase any of the following:

- seepage,
- levee settlement,
- wind erosion,
- bank erosion or bed scour,
- sediment deposition, or
- subsidence of land adjacent to levees.

In addition, an effect on the levee system is considered significant if an alternative would substantially decrease any of the following:

- levee stability;
- inspection, maintenance, or repair capabilities;
- current level of levee slope protection;
- emergency response capabilities;
- channel conveyance capacity; or
- the ability of the levees to withstand seismic forces.

4.4.3 Effects and Mitigation Measures

Effects related to mean sea level change are only addressed in the No Action Alternative in the program section because the WSLIP program area is relatively insensitive to the rates of sea-level rise. Of all the scenarios analyzed, only the high sea-level rise rate 100 years after the project is constructed shows greater than one-tenth of a foot stage increase in the Sacramento River, Yolo Bypass, or Sacramento Bypass in the WSLIP program area.

4.4.3.1 No Action Alternative

The No Action Alternative represents the continuation of the existing deficiencies along the portion of the Sacramento Bypass Levee reach in the CHP Academy EIP project area. Current levee operations and maintenance activities would continue, but there would be no change in the geomorphic and flood control regimes relative to existing conditions.

Because no levee improvements would be made under the No Action Alternative, the risk that the Sacramento Bypass Levee could fail due to seepage or slope stability or geometry issues would continue. Failure of the Sacramento Bypass Levee, depending on the magnitude of the event, could cause catastrophic flooding of the magnitude described in the Flood Control and Geomorphic Conditions program analysis (Section 3.2.3.3.1). In summary, those effects could include excessive saturation and weakening of all of the city's levees, reducing levee integrity and resulting in an even greater risk of levee collapse, failure and further flooding and damage. Additionally, proposed levee strengthening projects in upstream areas may transfer flood risk to the study area if the Sacramento Bypass Levee remains below current engineering standards while other upstream levees are improved to meet or exceed current standards. However, given the uncertainty of the occurrence or magnitude of such an event, potential effects on geomorphic and flood control conditions cannot be quantified based on available information. Compliance with future vegetation policy enforcement on the Sacramento Bypass Levee would not have any noteworthy effects on the geomorphic and/or flood control regimes of the Sacramento Bypass.

4.4.3.2 CHP Academy Applicant Preferred Alternative

Implementation of the CHP Academy APA would result in the following effects on hydrologic, hydraulic, geomorphic, and flood control issues. A description of these effects is provided below the summary table.

Effect	Finding	With Mitigation	Mitigation Measure
FC-3: Alteration of the Existing Drainage Pattern of the Site or Area	Significant	Less than significant	FC-MM-1: Coordinate with Owners and Operators, Prepare Drainage Studies as Needed, and Remediate Effects through Project Design
FC-6: Decrease in Through- and Under-Seepage	Beneficial	N/A	N/A
FC-7: Transfer of Seepage to Upstream or Downstream Levees	Less than significant	N/A	N/A
FC-8: Increase in Levee Slope Stability	Beneficial	N/A	N/A

Effect FC-3: Alteration of the Existing Drainage Pattern of the Site or Area

Implementation of slope flattening will involve earthwork on the landward side of the levee. The new material on the landside could alter surface runoff patterns. Because interference with drainage could cause or exacerbate local flooding, this effect may be significant. The implementation of Mitigation Measure FC-FC-MM-1 would reduce this effect.

Mitigation

Mitigation Measure FC-MM-1: Coordinate with Owners and Operators, Prepare Drainage Studies as Needed, and Remediate Effects through Project Design

WSAFCA and their primary contractors for engineering design and construction will ensure that the following measures are implemented to avoid significant effects associated with disruption of local drainage systems.

During project design, project engineers will coordinate with owners and operators of local drainage systems and landowners served by the systems to evaluate pre- and post-WSLIP drainage needs and design features to remediate any project-related substantial drainage disruption or alteration in runoff that would increase the potential for local flooding. If substantial alteration of runoff patterns or disruption of a local drainage system could result from a project feature, a drainage study will be prepared as part of project design. The study will consider the design flows of any existing facilities that would be crossed by project features and develop appropriate plans for relocation or other modification of these facilities and construction of new facilities, as needed, to ensure equivalent functioning of the system during and after construction. If no drainage facilities (e.g., ditches, canals) would be affected, but project features would have a substantial significant effect on runoff amounts and/or patterns, new drainage systems will be included in the design of project alternatives to ensure that the project would not result in new or increased local flooding. Any necessary features to remediate project-induced drainage problems will be constructed before the project is completed or as part of the project, depending on site-specific conditions.

Effect FC-6: Decrease in Through and Under-Seepage

Through- and under-seepage has the potential to weaken levee foundations. The implementation of a slurry cutoff wall would reduce or eliminate the potential for seepage. Slurry cutoff walls create walls of impermeable material that act as a barrier to water moving laterally through a levee, greatly reducing or eliminating the potential for through-seepage. Implementation of a slurry wall would result in beneficial effects on flood conditions in the study area.

Effect FC-7: Transfer of Seepage to Upstream or Downstream Levees

Installation of a slurry cutoff wall at the CHP Academy project area may have a slight effect on the potential for seepage to occur through levee sections immediately upstream or downstream, as a result of the redirection of hydraulic force.

However, the change in hydrologic conditions resulting from this treatment is not expected to result in a substantial increase in seepage through or under adjacent levees because any upstream or downstream levee will be engineered appropriately to an equal level of protection. Incremental improvements to the system will be made over a period of years and these improvements would reduce or eliminate any seepage problems.

This alternative is also not expected to have an effect on upstream or downstream water surface elevations because the height of the levee would not be increased and current seepage rates do not contribute to substantial reductions in channel flows or water surface elevations.

Effect FC-8: Increase in Levee Slope Stability

The proposed slope flattening will repair and reshape slopes that are too steep and do not meet current standards. This would result in an increase in levee slope stability and a beneficial effect for geomorphic and flood conditions.

4.4.3.3 CHP Academy Alternative B

Implementation of the CHP Academy Alternative B would result in the following effects on hydrologic, hydraulic, geomorphic, and flood control issues.

Effect	Finding	With Mitigation	Mitigation Measure
FC-3: Alteration of the Existing Drainage Pattern of the Site or Area	Significant	Less than significant	FC-MM-1: Coordinate with Owners and Operators, Prepare Drainage Studies as Needed, and Remediate Effects through Project Design
FC-8: Increase in Levee Slope Stability	Beneficial	N/A	N/A
FC-9: Redirection of Under-Seepage	Beneficial	N/A	N/A

Effect FC-3: Alteration of the Existing Drainage Pattern of the Site or Area

Implementation of slope flattening will involve earthwork on the landward side of the levee. The new material on the landside could alter surface runoff patterns. Because interference with drainage could cause or exacerbate local flooding, this effect may be significant. The implementation of Mitigation Measure FC-FC-MM-1, as described above under CHP APA, would reduce this effect to less than significant.

Effect FC-8: Increase in Levee Slope Stability

The construction of a stability berm on the landside of the Sacramento Bypass Levee would act as a buttress to stabilize the slope of the levee. Stabilizing slopes would increase levee slope stability and have a beneficial effect on flood control conditions.

Effect FC-9: Redirection of Under-Seepage

The proposed relief wells and interior drain will provide pathways to safely capture and release under-seepage and reduce the potential for under-seepage to weaken levee foundation soils via piping or sand boils. These project elements would create beneficial effects on geomorphic and flood conditions in the project area.

Section 4.5

Water Quality and Groundwater Resources—CHP Academy Early Implementation Project

4.5.1 Affected Environment

This section described the affected environment for water quality and groundwater resources in the CHP Academy EIP project area, including the regulatory and environmental settings.

4.5.1.1 Regulatory Setting

4.5.1.1.1 Federal

The following Federal regulations related to water quality and groundwater resources may apply to the CHP Academy EIP. Please see Section 3.3.2.1, Regulatory Setting, for a more complete description of each policy.

- Clean Water Act
- Section 404: Permits for Fill Placement in Waters and Wetlands
- Section 402: Permits for Discharge to Surface Waters
- Section401: Water Quality Certification
- Section 303: Impaired Waters

4.5.1.1.2 State

The following policies or agencies related to water quality and groundwater resources may apply to the CHP Academy EIP. Please see Section 3.3.2.1, Regulatory Setting, for a more complete description of each policy.

- Porter-Cologne Water Quality Control Act
- Central Valley Regional Water Quality Control Board
- Basin Plans and Water Quality Objectives
- Water Quality Objectives by Region
- State Implementation Plan

4.5.1.1.3 Local

The following local policies related to water quality and groundwater resources may apply to the implementation of the CHP Academy EIP. Please see Section 3.3.2.1, Regulatory Setting, for a more complete description of each policy.

- *City of West Sacramento General Plan*
- *Yolo County General Plan*

4.5.1.2 Environmental Setting

The following considerations are relevant to surface water quality and groundwater resources in the proposed CHP Academy EIP project area. The CHP Academy EIP project area is adjacent to the Sacramento River and involves work within the Sacramento Bypass. Existing surface water quality and groundwater quality are summarized below and more fully described in Section 3.32.2, Environmental Setting.

4.5.1.2.1 Surface Water Quality

The water quality of the Sacramento River is good to excellent, with relatively cool water temperatures, low BOD, medium to high DO, and low mineral and nutrient content. In general, the surface water quality of the Sacramento River is representative of agricultural return flows, urban runoff, and natural sedimentation from scouring. Water quality issues of concern within the Sacramento River include TSS and turbidity, DO, temperature, electrical conductivity, and pH. The Sacramento bypass diverts Sacramento River flood flows around the city of West Sacramento.

4.5.1.2.2 Groundwater Quality

Groundwater levels in the Yolo Sub-basin are affected by drought, pumping, and reduced surface water discharge. Groundwater quality is considered good for agricultural and municipal purposes, although the water is hard.

4.5.2 Environmental Consequences

This section describes the environmental consequences relating to surface water and groundwater quality for the proposed CHP Academy EIP. It describes the methods used to determine the effects of the project and lists the thresholds used to conclude whether an effect would be significant. The effects tier from the program analysis effects described in Section 3.3.3.3, Effects and Mitigation Measures.

4.5.2.1 Assessment Methods

This evaluation of surface water quality and groundwater quality is based on professional standards and information obtained from the Central Valley RWQCB, State Water Board, and DWR.

The key effects were identified and evaluated based on the environmental characteristics of the CHP Academy EIP project area and the magnitude, intensity, and duration of activities related to the construction of this project.

4.5.2.2 Determination of Effects

For this analysis, an effect pertaining to surface water quality and groundwater quality was considered significant under NEPA and CEQA if it would result in any of the following environmental effects, which are based on NEPA standards, State CEQA Guidelines Appendix G (14 CCR 15000 *et seq.),* and standards of professional practice:

- violate water quality standards or waste discharge requirements;

- substantially deplete groundwater supplies or interfere substantially with ground water recharge;
- substantially degrade water quality; or
- alter regional or local hydrology resulting in substantial increases in erosion or sedimentation.

4.5.3 Effects and Mitigation Measures

4.5.3.1 No Action Alternative

The No Action Alternative represents the continuation of existing deficiencies along the portion of the Sacramento Bypass Levee reach in the CHP Academy EIP project area. No levee alternatives would be made to increase the level of protection. No construction-related effects relating to water quality such as earthmoving that result in increased turbidity, or incidental releases of construction-related contaminants would occur. Therefore, there would be no effect on surface or groundwater quality or resources attributable to the implementation of the No Action Alternative.

Because no levee improvements would be made under the No Action Alternative, the risk that the Sacramento Bypass Levee could fail due to seepage or slope stability or geometry issues would continue. Failure of the Sacramento Bypass Levee, depending on the magnitude of the event, could cause catastrophic flooding of the entire city of the magnitude described in the Water Quality and Groundwater Resources program analysis (Section 3.3.3.3.1). In summary, those effects could include spreading of contaminants from stored chemicals, septic systems, and flooded vehicles into the Sacramento Bypass, Yolo Bypass, Delta, and other nearby waterways, as well as potentially contaminating soils and groundwater. Loss of eroded levee foundation and eroded topsoil from inundated areas would increase turbidity and total dissolved solids in nearby waterways, impairing beneficial uses. Furthermore, if a levee breach were to occur, emergency construction and repair activities would likely be implemented without the use of BMPs and could result in the release of hazardous construction materials such as oil and other petroleum related products. However, the timing, duration and magnitude of a flood event are speculative and unpredictable, and therefore a precise determination of significance is not possible.

4.5.3.2 CHP Academy Applicant Preferred Alternative

Implementation of the CHP Academy APA would result in the following effects on water quality and groundwater resources. A description of these effects is provided below the summary table.

Effect	Finding	With Mitigation	Mitigation Measure
WQ-1: Effects on Surface Water Quality from Excessive Turbidity or Total Suspended Solids	Less than significant	N/A	
WQ-2: Release of Contaminants into Adjacent Surface Water Bodies from Construction-Related Hazardous Materials	Less than significant	N/A	

Effect	Finding	With Mitigation	Mitigation Measure
WQ-3: Effects on Groundwater or Drinking Water Quality Resulting from Construction and Operation	Significant	Less than significant	WQ-MM-1 Implement Measures to Maintain Surface Water Quality and Groundwater Quality WQ-MM-2: Implement Provisions for Dewatering

Effect WQ-1: Effects on Surface Water Quality from Excessive Turbidity or Total Suspended Solids

The project involves earth-moving activities (i.e., degrading the levee prior to slurry wall construction and slope flattening) that could cause sedimentation and erosion in adjacent water bodies. The development of a SWPPP, an environmental commitment (see Section 2.9 of Chapter 2, Alternatives, for a full description) included as part of this project would reduce the likelihood that this effect would occur, or reduce the effect should it occur. This commitment includes the development of a SWPPP. Site-specific erosion control measures would be developed as part of a SWPPP, a requirement of the NPDES General Construction Permit. A SWPPP typically contains, but is not limited to, the following described best management practices:

- **Timing of construction.** Conduct earthwork during the typical construction season.
- **Staging of construction equipment and materials.** Stage construction equipment and materials on the landside of the subject levee reaches. To the extent possible, stage equipment and materials in areas that already have been disturbed.
- **Soil and vegetation disturbance.** Minimize ground and vegetation disturbance during construction by establishing designated equipment staging areas, ingress and egress corridors, spoils disposal and soil stockpile areas, and equipment exclusion zones prior to the commencement of any grading operations.
- **Grading spoils.** Stockpile soil and grading spoils on the landside of the subject levee reaches, and install sediment barriers (e.g., silt fences, fiber rolls, straw bales) around the base of stockpiles to intercept runoff and sediment during storm events. If necessary, cover stockpiles with geotextile fabric to provide protection against wind and water erosion.
- **Sediment barriers.** Install sediment barriers on graded or otherwise-disturbed slopes as needed to prevent sediment from leaving the project site and entering nearby surface waters.
- **Site stabilization.** Install native plant materials to stabilize cut and fill slopes and other disturbed areas once construction is complete. Plant materials may include an erosion control seed mixture or shrub and tree container stock. Temporary structural BMPs, such as sediment barriers, erosion control blankets, mulch, and a mulch tackifier, may be installed as needed to stabilize disturbed areas until vegetation becomes established.

Effect WQ-2: Release of Contaminants into Adjacent Water Bodies from Construction-Related Hazardous Materials

Program actions may involve storage, use, or discharge of toxic and other harmful substances near water bodies (or in areas that drain to these water bodies, e.g., the Sacramento River). Construction activities would involve the use of heavy equipment, cranes, compactors and other construction

equipment that uses petroleum products (e.g., fuels, lubricants, hydraulic fluids, coolants). All of these materials may be toxic to fish and other aquatic organisms. An accidental spill or inadvertent discharge of these materials could affect the water quality of the river or water body.

There are three environmental commitments included as part of this project that would reduce the effect of such a release should it occur or reduce the likelihood that a release would occur. These environmental commitments include the development of the SWPPP, SPCCP and a bentonite slurry spill contingency plan (BSSCP). Typical elements of the SWPPP are described above under Effect WQ-1, above. All three environmental commitments are described in detail in Section 2.9 of Chapter 2, Alternatives, and are summarized below.

An SPCCP is intended to prevent any discharge of oil into navigable water or adjoining shorelines. WSAFCA or its contractor will develop and implement an SPCCP to minimize the potential for and effects from spills of hazardous, toxic, or petroleum substances during construction and operation activities. The SPCCP will be completed before any construction activities begin. Implementation of this measure will comply with state and Federal water quality regulations. The SPCCP will describe spill sources and spill pathways in addition to the actions that would be taken in the event of a spill (e.g., an oil spill from engine refueling would be immediately cleaned up with oil absorbents). The SPCCP will outline descriptions of containments facilities and practices such as doubled-walled tanks, containment berms, emergency shut-offs, drip pans, fueling procedures and spill response kits. It will also describe how and when employees are trained in proper handling procedure and spill prevention and response procedures.

A BSSCP is typically developed for activities that involve the use of bentonite materials (e.g., the construction of slurry walls). The BSSCP is intended to minimize the potential for a frac-out associated with excavation and tunneling activities, provide for timely detection of frac-outs, and ensure and "minimum-effect" response in the event of a frac-out and release of excavation fluid (i.e., bentonite used for the construction of slurry walls).

Release of contaminants into adjacent water bodies could result in significant effects. Adherence to these environmental commitments and the implementation of Mitigation Measure WQ-MM-1 should spills occur would reduce this effect to less than significant.

Mitigation

Mitigation Measure WQ-MM-1: Implement Measures to Maintain Surface Water Quality and Groundwater Quality

If an appreciable spill has occurred and results determine that project activities have significantly affected surface or groundwater quality, a detailed analysis will be performed by a registered environmental assessor or professional engineer to identify the likely cause of contamination. This analysis will conform to American Society for Testing and Materials (ASTM) standards and will include recommendations for reducing or eliminating the source or mechanisms of contamination. Based on this analysis, WSAFCA and its contractors will select and implement measures to control contamination, with a performance standard that surface water quality and groundwater quality must be returned to baseline conditions.

Effect WQ-3: Effects on Groundwater or Drinking Water Quality Resulting from Construction and Operation

Trenching and excavation associated with the construction of slurry walls may reach a depth that could expose the water table, in which case an immediate and direct path to the groundwater basin would become available for contaminants to enter the groundwater system. Primary construction-related contaminants that could reach groundwater include increased sediment, oil and grease, and hazardous materials.

In addition, while dewatering of the construction area (e.g., trenches dug for slurry wall construction that may be filled with groundwater) is not expected to occur, if it became necessary, it could result in the release of contaminants to surface or groundwater.

The implementation of the CHP Academy project is not expected to require digging or trenching at depths where groundwater aquifers utilized for drinking water occur. If trenching activities were to incidentally reach a groundwater aquifer utilized for drinking water, the slurry wall material is relatively benign and would not remain in a liquid state long enough to allow for significant lateral movement within the aquifer.

As discussed in Section 4.19, Public Health and Hazards, prior to all construction activities, WSAFCA will complete Phase I and, if necessary, Phase II Environmental Site Assessment Investigations that will include analysis of soil and/or groundwater samples for the potential contamination sites that have not yet been covered by previous investigations. If hazardous substances are found, WSAFCA or its contractor will implement required measures for the proper transport and disposal of such materials in accordance with the appropriate local, state and Federal laws and regulations.

Effect on groundwater and drinking water quality from operation and construction could be significant. The proposed program would adhere to environmental commitments of the SWPPP, the SPCCP, and the BSSCP, as summarized above under Effects WQ-1 and WQ-2. Adherence to environmental commitments of the SWPPP, SPCCP, and the BSSCP and the implementation of Mitigation Measures WQ-MM-1 and WQ-MM-2 would reduce this effect to less than significant.

Mitigation

Mitigation Measure WQ-MM-1 Implement Measures to Maintain Surface Water Quality and Groundwater Quality

Mitigation Measure WQ-MM-2: Implement Provisions for Dewatering

Before discharging any dewatered effluent to surface water, WSAFCA or its contractors will obtain a Low Threat Discharge and Dewatering NPDES permit from the Central Valley RWQCB. Depending on the volume and characteristics of the discharge, coverage under the Central Valley RWQCB's NPDES General Construction Permit or General Dewatering Permit is possible. As part of the permit, the permittee will design and implement measures as necessary so that the discharge limits identified in the relevant permit are met. For example, if dewatering is needed during the construction of the slurry wall, then the Low Threat Discharge and Dewatering NPDES permit would require proper disposal of the water due to the known petroleum plume present in the area. As a performance standard, these measures will be selected to achieve maximum sediment removal and represent the best available technology that is economically achievable. Implemented measures may include the retention of dewatering effluent until particulate matter has settled before it is discharged, use of

infiltration areas, and other BMPs. Final selection of water quality control measures will be subject to approval by WSAFCA.

WSAFCA will verify that coverage under the appropriate NPDES permit has been obtained before allowing dewatering activities to begin. WSAFCA or its agent will perform routine inspections of the construction area to verify that the water quality control measures are properly implemented and maintained. WSAFCA will notify its contractors immediately if there is a non-compliance issue and will require compliance.

4.5.3.3 CHP Academy Alternative B

Implementation of the CHP Academy Alternative B would result in the following effects on water quality and groundwater resources. A description of the effects is provided below the summary table.

Effect	Finding	With Mitigation	Mitigation Measure
WQ-1: Effects on Surface Water Quality from Excessive Turbidity or Total Suspended Solids	Less than significant	N/A	
WQ-2: Release of Contaminants into Adjacent Surface Water Bodies from Construction-Related Hazardous Materials	Less than significant	N/A	
WQ-3: Effects on Groundwater or Drinking Water Quality Resulting from Construction and Operation	Significant	Less than significant	WQ-MM-1 Implement Measures to Maintain Surface Water Quality and Groundwater Quality WQ-MM-2: Implement Provisions for Dewatering

Effect WQ-1: Effects on Surface Water Quality from Excessive Turbidity or Total Suspended Solids

Effects on surface water quality from excessive turbidity or total suspended solids are the same for Alternative B as that described for Alternative A, above, For Alternative B, the earth moving activities that would cause such an effect are those associated with slope flattening and stability berm construction Environmental commitments remain the same. This effect is considered less than significant. No mitigation is required.

Effect WQ-2: Release of Contaminants into Adjacent Water Bodies from Construction-Related Hazardous Materials

The effects described under the CHP APA, above, also apply to Alternative B. However, Alternative B would not require the implementation of a BSSCP because no slurry wall construction is involved in Alternative B. This effect is considered less than significant. No mitigation is required.

Effect WQ-3: Effects on Groundwater or Drinking Water Quality Resulting from Construction and Operation

Trenching and excavation associated with the construction of the interior drain, stability berm and relief wells may reach a depth that could expose the water table, in which case an immediate and

direct path to the groundwater basin would become available for contaminants to enter the groundwater system. Primary construction-related contaminants that could reach groundwater include increased sediment, oil and grease, and hazardous materials.

In addition, while dewatering of the construction area (e.g., trenches dug for slurry wall construction that may be filled with groundwater) is not expected to occur, if it became necessary, it could result in the release of contaminants to surface or groundwater.

The implementation of the CHP Academy Alternative B is not expected to require digging or trenching at depths where groundwater aquifers utilized for drinking water occur. Therefore no effects on drinking water would occur. As discussed in Section 4.19, Public Health and Hazards, prior to all construction activities, WSAFCA will complete Phase I and, if necessary, Phase II Environmental Site Assessment Investigations that will include analysis of soil and/or groundwater samples for the potential contamination sites that have not yet been covered by previous investigations. If hazardous substances are found, WSAFCA or its contractor will implement required measures for the proper transport and disposal of such materials in accordance with the appropriate local, state and Federal laws and regulations.

Effect on groundwater and drinking water quality from operation and construction could be significant. The proposed program would adhere to environmental commitments of the SWPPP, and the SPCCP, as summarized above under CHP APA Effects WQ-1 and WQ-2. Adherence to environmental commitments of the SWPPP, and the SPCCP and the implementation of Mitigation Measures WQ-MM-1 and WQ-MM-2 would reduce this effect to less than significant.

Section 4.6

Geology, Seismicity, Soils, and Mineral Resources—CHP Academy Early Implementation Project

4.6.1 Affected Environment

This section describes the affected environment for geology, seismicity, soils, and mineral resources in the CHP Academy EIP project area, including the regulatory and environmental setting.

4.6.1.1 Regulatory Setting

4.6.1.1.1 State

The following state policies related to geology, seismicity, soils, and mineral resources may apply to the implementation of the CHP Academy EIP. Please see the program information in Section 3.4.2.1, Regulatory Setting, for a more complete description of each policy.

- Alquist-Priolo Earthquake Fault Zoning Act
- Seismic Hazards Mapping Act
- California Building Standards Code
- California Surface Mining and Reclamation Act

4.6.1.1.2 Local

The following local policies related to geology, seismicity, soils, and mineral resources may apply to the implementation of the CHP Academy EIP. Please see the program information in Section 3.4.2.1, Regulatory Setting, for a more complete description of each policy.

- *Draft 2030 Countywide General Plan* for Yolo County
- *City of West Sacramento General Plan*
- Grading and Erosion Control Ordinances

4.6.1.2 Environmental Setting

This section discusses the environmental setting related to soil characteristics, mineral resources, and seismic hazards for the CHP Academy EIP.

4.6.1.2.1 Study Area

Geology and Topography

The surface and subsurface distributions of sandy and clayey deposits in the CHP Academy EIP project area are a function of former river positions on the landscape, present-day geomorphic processes adjacent to the river positions on the landscape, and present-day geomorphic processes

adjacent to the river channel (i.e., flooding and deposition) (William Lettis & Associates 2007). Helley and Harwood (1985) compiled previous regional studies of the quaternary geology of the Sacramento Valley. Previous geologic mapping in the West Sacramento study area generalized the surficial deposits as Quaternary alluvium (Qa) proximal to the modern river channel and undifferentiated Quaternary basin (Qb) deposits away from the modern river channel. Helley and Harwood (1985) differentiate basin deposits from alluvium on the basis of composition, including only those deposits that are finer-grained and frequently organic-rich, and suggests these deposits were distal deposits where energy conditions were much lower. Both of these map units are considered Holocene age.

Geologic mapping indicates that the Sacramento Bypass Levee is underlain by a combination of alluvium and basin deposits (Helley and Harwood 1985) and buried sandy crevasse splay deposits (William Lettis & Associates 2007).

4.6.1.2.2 Soils

The CHP Academy EIP project area comprises three distinct soil map units as identified by the USDA Conservation Service (U.S. Department of Agriculture Soil Conservation Service 1972): Lang sandy loam, deep, Lang sandy loam, deep, flooded, and Sycamore silt loam (Figure 4.6-1). These soil types are characterized in Table 3.4-1, Section 3.4.2.2.2. The under-seepage deficiencies identified at the CHP Academy project area are caused primarily by the presence at depth of coarse, permeable soils (sands and gravels) that translate hydraulic pressure during flood stage beneath the levees and destabilize them. In other words, the coarse-textured soil material common to the Lang and Sycamore soil series found at the CHP Academy project area facilitates seepage pathways, which compromise levee integrity.

4.6.1.2.3 Mineral Resources

No commercial mining operations are known to have occurred in West Sacramento. Most of the area is classified as MRZ-1 by the California Division of Mines and Geology, which indicates no significant mineral deposits are present. The portion of the West Sacramento area that borders the Sacramento River (and henceforth the study area vicinity) is classified as MRZ-3, which means aggregate deposits of undetermined significance occur there. Lands classified as MRZ-1 or MRZ-3 are not affected by state policies pertaining to the maintenance of access to regionally significant mineral deposits under the California Surface Mining and Reclamation Act of 1975.

4.6.1.2.4 Seismic Hazards

Seismic hazards refer to earthquake fault ground rupture and ground shaking (primary hazards), as well as liquefaction and earthquake-induced slope failure (secondary hazards). Localized ground shaking and liquefaction are the most significant seismic hazards in Yolo County (Yolo County 1983).

Primary Seismic Hazards—Surface Fault Rupture[1] and Groundshaking

The project area is located in a region of California characterized by low seismic activity. The UBC recognizes no active seismic sources in the project vicinity (International Conference of Building

[1] *Surface fault rupture* is a rupture at the ground surface along an active fault, caused by earthquake or creep activity.

Officials 1997), and no active faults are known to cross the project area. The project area is located within UBC Seismic Hazard Zone 3. Refer to the program description for further information.

Liquefaction

Poorly consolidated, water-saturated fine sands located within 30 to 50 feet of the surface typically are considered the most susceptible to liquefaction. Soils and sediments that are not water-saturated and that consist of coarser or finer materials are generally less susceptible to liquefaction (California Division of Mines and Geology 1997).

URS performed a liquefaction-triggering analysis to evaluate whether any levee or underlying foundation materials potentially would liquefy during the considered earthquake events. Criteria for susceptibility to liquefaction included soil type, liquid limit, plasticity index, water content, and fines content. If the material was considered to be susceptible to liquefaction, steps were completed to further evaluate the liquefaction potential of the material considering the earthquake loading. In contrast, if the plasticity of the material was high enough to preclude liquefaction, the material was classified as non-liquefiable, irrespective of the earthquake loading (URS 2007). The Sacramento Bypass may exhibit liquefaction during a seismic event (HDR, Inc. 2008a).

4.6.2 Environmental Consequences

This section describes the environmental consequences relating to geology, seismicity, soils, and mineral resources for the proposed CHP Academy EIP. It describes the methods used to determine the effects of the project and lists the thresholds used to conclude whether an effect would be significant. The effects that would result from implementation of the CHP Academy EIP, findings with or without mitigation, and applicable mitigation measures are presented in a summary table. These effects tier from the program analysis effects, described in Section 3.4.3.3, Effects and Mitigation Measures.

4.6.2.1 Assessment Methods

Evaluation of the geology, seismicity, and soils effects in this section is based on the information provided by technical maps, reports, and other documents that describe the geologic, seismic, and soil conditions of the study area. This information was then compared to the type and location of proposed flood and recreation alternatives to determine whether effects would occur.

4.6.2.2 Determination of Effects

Criteria for determining the significance of effects related to geology, soils, and mineral resources were developed based on the environmental checklist form in Appendix G of the State CEQA Guidelines (14 CCR 15000 *et seq.*). An effect related to geology, soils, and seismicity was considered significant if it would:

- expose people or structures to potential substantial adverse effects, including the risk of loss, injury, or death involving:
- rupture of a known earthquake fault, as delineated on the most recent Alquist-Priolo Earthquake Fault Zoning Map issued by the state geologist for the area or based on other

Q:\PROJECTS\HDR\00875_07\MAPDOC\SOILS\CHP_SOIL_MAP_8_1_2X11_20091118.MXD SS (11.19.09)

Figure 4.6-1
Soil Types at the CHP Academy Early Implementation Site

substantial evidence of a known fault (refer to Division of Mines and Geology Special Publication 42);

- strong seismic ground shaking;
- seismic-related ground failure, including liquefaction; or
- landslides;
- result in substantial soil erosion or the loss of topsoil;
- be located on a geologic unit or soil that is unstable or that would become unstable as a result of the project and potentially result in an on-site or off-site landslide, lateral spreading, subsidence, liquefaction, or collapse;
- be located on expansive soil, as defined in Table 18-1-B of the UBC (1994), creating substantial risks to life or property;
- have soils incapable of adequately supporting the use of septic tanks or alternative wastewater disposal systems in areas where sewers are not available for the disposal of wastewater;
- result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the state; or
- result in the loss of availability of a locally important mineral resource recovery site delineated on a local general plan, specific plan, or other land use plan.

4.6.3 Effects and Mitigation Measures

4.6.3.1 No Action Alternative

The No Action Alternative represents the continuation of existing deficiencies along the portion of the Sacramento Bypass Levee reach in the CHP Academy EIP project area. No levee improvements would be made to increase the level of protection. No construction-related effects involving direct ground-disturbing activities or changes to flood control facilities that could result in changes in geology, seismicity, soils, or mineral resources would occur.

Because no levee improvements would be made under the No Action Alternative, the risk that the Sacramento Bypass Levee could fail due to seepage or slope stability or geometry issues would continue. Failure of the Sacramento Bypass Levee, depending on the magnitude of the event, could cause catastrophic flooding of the entire city of the magnitude described in the Geology, Seismicity, and Soils program analysis (Section 3.4.3.3.1). In summary, these effects could include loss of topsoil, additional levee collapse, alteration of regional and local hydrology, and an increase in erosion and sedimentation. It is assumed that these effects would be significant; however, given the uncertainty of the occurrence or magnitude of such an event, the effects cannot be quantified based on available information.

Furthermore, the beneficial effects attributable to program implementation such as improved levee stability and decreased levee bank erosion would not be realized under the No Action Alternative.

4.6.3.2 CHP Academy Applicant Preferred Alternative

Implementation of the CHP Academy APA would result in the following effects on geology, seismicity, soils, and mineral resources. A description of these effects is provided below the summary table.

Effect	Finding	With Mitigation	Mitigation Measure
GEO-1: Effects on Levee Stability	Beneficial	N/A	N/A
GEO-3: Effects Resulting from Seismic Groundshaking and Liquefaction	Less than significant	N/A	N/A
GEO-4: Accelerated Erosion and Sedimentation Resulting from Construction-Related Ground Disturbance	Less than significant	N/A	N/A
GEO-5: Structural Damage and Injury from Development on Expansive Soils	Significant	Less than significant	GEO-MM-1: Implement the Corrective Actions Identified as Part of a Project-Specific Geotechnical Report

Effect GEO-1: Effects on Levee Stability

The proposed slope flattening would improve the stability of the Sacramento Bypass Levee by further reducing seepage and the potential for seepage-related failures by reducing hydrostatic exit gradients, creating more stable slopes and reducing erosion. Therefore, this effect would be beneficial.

Effect GEO-3: Effects Resulting from Seismic Groundshaking and Liquefaction

Based on available knowledge of fault location and locations of earthquake epicenters, the risk of groundshaking in the study area is low. Nonetheless, a large earthquake on a nearby fault could cause groundshaking in the study area, which could result in liquefaction or associated ground failure, such as lateral spreading or differential settlement which could in turn result in structural loss, injury, and death.

The Sacramento Bypass levee contains soils that may be subject to liquefaction. Implementation of the proposed CHP APA would not substantially alter the composition of the subject levees or foundation soils or increase their susceptibility to liquefaction. The CHP APA does propose the construction of a slurry cutoff wall to reduce seepage and increase flood control that might sustain damage from groundshaking or liquefaction and endanger people during a seismic event.

However, the potential for failure of this structure from groundshaking would depend on the degree of levee saturation during an earthquake. A high level of saturation would likely only occur during a major flood event. The probability that a large regional earthquake would occur during a major flood event is relatively low, but such coincidence is not impossible. Nonetheless, because of the relative small likelihood of such coincidental events, and because the expected magnitude of groundshaking from large regional earthquakes is relatively low in the study area, the potential for failure or damage of the slurry cutoff wall is considered to be less than significant. No mitigation is required.

Effect GEO-4: Accelerated Erosion and Sedimentation Resulting from Construction-Related Ground Disturbance

The grading, trenching, and other earthwork that would be conducted during construction of the CHP APA would result in substantial ground and vegetation disturbance. These disturbances would increase the hazard of erosion and could temporarily increase erosion and sedimentation rates above existing levels. Because most of the earthwork would be conducted on and immediately adjacent to the levee, accelerated erosion and sedimentation resulting from construction-related ground and vegetation disturbance would not result in the loss of appreciable quantities of topsoil resources. In addition, most ground-disturbing activities would occur during the typical construction season, when conditions are generally dry, further reducing the potential for construction-related erosion.

Site-specific measures that would control erosion would be described in more detail in the SWPPP, which is included in the environmental commitments of the program, described in further detail in Section 2.9 of Chapter 2, Alternatives, and summarized in Section 4.5, Water Quality of this chapter. The SWPPP is a requirement of the NPDES General Construction Permit.

With this project-level action, erosion and sediment-related effects would be less than significant. No mitigation is required.

Effect GEO-5: Structural Damage and Injury Resulting from Development on Expansive Soils

According to the soil survey for Yolo County, moderate to high shrink-swell potential (soil expansiveness) exists in the study area within the Sacramento Bypass Levee reaches. Additionally, expansive soil and sediments were encountered at various depths below the levees in the study area during geotechnical investigations (Kleinfelder 2007). Expansive soils have the potential to compromise the structural integrity of the proposed slurry cutoff wall.

As previously discussed, WSAFCA would require the preparation of a preliminary soil report based on soil borings and, if expansive or weak soils are documented on site, a soils investigation detailing corrective action. These corrective actions likely would prevent structural damage. This effect would be significant, but implementation of Mitigation Measure GEO-MM-1 would reduce this effect to less than significant.

Mitigation

Mitigation Measure GEO-MM-1: Implement the Corrective Actions Identified as Part of a Project-Specific Geotechnical Report

WSAFCA will implement special engineering techniques identified in a project-specific geotechnical report, which may include using reinforced steel and drainage control devices, and/or over-excavating and backfilling with non-expansive soil. WSAFCA or its contractor will select one or more of the recommended measures in consultation with a qualified engineer and the WSAFCA engineer before construction activities begin.

4.6.3.3 CHP Academy Alternative B

Implementation of the CHP Academy Alternative B would result in the following effects on geology, seismicity, soils, and mineral resources. A description of these effects is provided below the summary table.

Effect	Finding	With Mitigation	Mitigation Measure
GEO-1: Effects on Levee Stability	Beneficial	N/A	N/A
GEO-3: Effects Resulting from Seismic Groundshaking and Liquefaction	Less than significant	N/A	N/A
GEO-4: Accelerated Erosion and Sedimentation Resulting from Construction-Related Ground Disturbance	Less than significant	N/A	N/A
GEO-5: Structural Damage and Injury from Development on Expansive Soils	Significant	Less than significant	GEO-MM-1: Implement the Corrective Actions Identified as Part of a Project-Specific Geotechnical Report

Effect GEO-1: Effects on Levee Stability

The proposed stability berm, interior drain and relief wells would improve the stability of the Sacramento Bypass Levee by further reducing seepage and the potential for seepage-related failures by reducing hydrostatic exit gradients, creating more stable slopes and reducing erosion. Therefore, this effect would be beneficial.

Effect GEO-3: Effects Resulting from Seismic Groundshaking and Liquefaction

This effect is the same as that described under the CHP APA, above, with the exception of the structures that may sustain damage are a stability berm, interior drain, and relief wells. The effect is considered less than significant. No mitigation is required.

Effect GEO-4: Accelerated Erosion and Sedimentation Resulting from Construction-Related Ground Disturbance

This effect is the same as that described under the CHP APA, above. This effect is considered less than significant. No mitigation is required.

Effect GEO-5: Structural Damage and Injury Resulting from Development on Expansive Soils

The effect and mitigation measure are the same as that described under the CHP APA, above. The effect is considered less than significant with the implementation of mitigation measure, GEO-MM-1, also described above.

Section 4.7

Transportation and Navigation—CHP Academy Early Implementation Project

4.7.1 Affected Environment

This section describes the affected environment for transportation and navigation in the CHP Academy EIP project area, including the regulatory and environmental settings.

4.7.1.1 Terminology

The following are definitions of key traffic and transportation terms used in this section, in addition to the definitions provided in Section 3.5.1.1.

- **Annual average daily traffic (AADT)**: AADT is the total traffic volume for the year divided by 365 days.
- **Peak Hour:** This is an estimate of the peak hour traffic at all points on the state highway system.
- **Back and Ahead**: Back AADT, Peak Month, and Peak Hour usually represent traffic south or west of the count location. Ahead AADT, Peak Month, and Peak Hour usually represent traffic north or east of the count location.

4.7.1.2 Regulatory Setting

4.7.1.2.1 Federal

The following Federal policies related to transportation and navigation may apply to the implementation of the CHP Academy EIP. Please see the program information in Section 3.5.2.1, Regulatory Setting, for a more complete description of each policy.

- River and Harbors Appropriation Act of 1899

4.7.1.2.2 Local

The following local policies related to transportation and navigation may apply to the implementation of the CHP Academy EIP. Please see Section 3.5.2.1, Regulatory Setting, for a more complete description of each policy.

- *City of West Sacramento General Plan*
- *Yolo County General Plan*

4.7.1.3 Environmental Setting

This section discusses the environmental setting related to transportation and navigation in the study area for the CHP Academy EIP.

4.7.1.3.1 Roadways

Existing freeways within or near the project area are described below.

- **Interstate 80 (I-80)** is a major freeway that runs northeast to southwest at the southeastern edge of the project area. I-80 heads toward Reno to the east and San Francisco to the west. The freeway runs above the Sacramento River North Levee, and would not be affected by the proposed project.
- **Highway 50 (US 50)** is a major highway that runs east to west, south of the project area. US 50 heads towards Carson City to the east and merges with I-80 on the western side of West Sacramento as it heads towards San Francisco.

Table 4.7-1 shows the Back and Ahead AADT for the highway segments that would be most affected by project-related traffic.

Table 4.7-1. AADT for Highways in the CHP Academy Project Area

Highway	Segment	Back AADT	Ahead AADT
I-80	Junction with Route 50	145,000	85,000
I-80	Junction with Route 84 (Reed Avenue)	85,000	90,000
I-80	West El Camino Avenue Interchange	90,000	87,000
US 50	Junction with Route 80	–	85,000
US 50	Harbor Boulevard Interchange	85,000	116,000

Source: California Department of Transportation 2009.

The major arterial streets that serve the project area or that may be affected by project implementation are:

- **Reed Avenue/Sacramento Avenue/C Street (SR 84)** runs east-west between I-80 near the western City Limits and the I Street Bridge at the Sacramento River. The roadway width varies between two and four lanes. Reed Avenue is classified under the LOS Criteria for Roadway Segments as a four-lane arterial with moderate access control.
- **North Harbor Boulevard** runs north-south parallel to the Sacramento River North Levee and crosses the easternmost end of the Sacramento Bypass Levee before continuing over the Sacramento Bypass. In the section of the road adjacent to the project area, Harbor Boulevard is a two-lane road. Harbor Boulevard is classified as a two-lane arterial with moderate access control.

Local roads that run adjacent to or along the crest of the project area levees include Tule Jake Road and various roadways that are part of the CHP Academy EIP project area. Tule Jake Road is a gravel road that runs along the crest of the Sacramento Bypass Levee and is accessible to maintenance vehicles only. The roads on the CHP Academy EIP project area are used for training and would not be affected by project implementation. Table 4.7-2 shows the ADT, peak-hour traffic, and LOS for these major roadways.

Table 4.7-2. ADT, Peak-Hour Traffic, and LOS for Major Roadways in the CHP Academy Project Area

Street	Limits	ADT	AM Peak	PM Peak	LOS	Count Year
North Harbor Boulevard	Riverbank Road to Reed Avenue	4,529	467	484	A	2007
North Harbor Boulevard	City Limits to Riverbank Road	4,801	354	484	A	2007
Reed Avenue	Riverside Parkway to Sunset Avenue	15,930	1,036	1,229	A	2005

Source: City of West Sacramento 2007.

According to the City's LOS standards, all three haul route segments that lie within or near the project area have a LOS of A.

4.7.1.3.2 Parking

On-street parking in the project area is limited to the shoulder of North Harbor Boulevard and gravel area at the entrance to Tule Jake Road. The City does not have any public parking lots in or near the project area. Construction projects are subject to off-street parking standards as defined in the City's Zoning Ordinance (City of West Sacramento 2000).

4.7.1.3.3 Railroads

The Union Pacific Railroad runs parallel to North Harbor Boulevard on the western side of the street (adjacent to Sacramento River North Levee). The railroad runs southeast to northwest, and crosses the eastern end of the Sacramento Bypass Levee as it runs from the City to Woodland (City of West Sacramento 2009b).

4.7.1.3.4 Transit Facilities

Yolo Bus 240, which runs from West Sacramento to Sacramento, runs along Reed Avenue, south of the project area. No other transit facilities are located within the project area (Yolo county Transportation District 2009).

4.7.1.3.5 Bikeways

Bicycle facilities are currently available in the project vicinity. Major arterial roads and several minor arterial roads throughout the city have bike lanes or bike-accessible shoulders. Bike-accessible areas that run adjacent to or on top of levees in the project vicinity include North Harbor Boulevard (Sacramento River North Levee) (City of West Sacramento 2009a).

4.7.1.3.6 Airports

Airports in the area include Sacramento International Airport, Sacramento Executive Airport, Mather Airport, and Franklin Field. Sacramento International Airport is Sacramento County-owned and is located approximately 7 miles north of the city, between Sacramento and Woodland along I-5. The Executive Airport is owned by Sacramento County and is located 1.5 miles to the east of the city, within the city of Sacramento. Mather Field is a military airfield located approximately 11 miles east of the City in Rancho Cordova. Franklin Field is owned by Sacramento County and is located approximately 16 miles south of the city in Elk Grove.

4.7.1.3.7 Navigation

The Sacramento River is the only permanent waterway that lies adjacent to the project area. The river flows in a generally southward direction past the Sacramento River North Levee. The river is approximately 650 feet wide where it passes the project area; however, widths vary with water elevations. Navigation in the Sacramento River is limited to recreational watercraft because the river is too small and fluctuating water levels prevent the accommodation of large commercial vessels.

On the West Sacramento bank, in the project vicinity, there are no docks or other access points to the river. On the city of Sacramento side, there are several private docks that belong to homeowners living on top of or adjacent to the levee.

4.7.2 Environmental Consequences

This section describes the environmental consequences relating to transportation and navigation for the proposed CHP Academy EIP project area. It describes the methods used to determine the effects of the project and lists the thresholds used to conclude whether an effect would be significant. The effects that would result from implementation of CHP Academy EIP project, findings with or without mitigation, and applicable mitigation measures are presented in a summary table. These effects tier from the program analysis effects described in Section 3.5.3.3, Effects and Mitigation Measures.

4.7.2.1 Assessment Methods

The proposed project would construct levee alternatives along a section of the Sacramento Bypass Levee. Because of the earthwork involved and the need for materials deliveries, construction would intermittently generate substantial volumes of traffic. Once the construction is completed, maintenance needs would be similar to current conditions. Analysis of traffic effects therefore concentrated on the construction of levee alternatives.

For the purposes of analysis, the effects of these project activities were analyzed according to truck and worker trip effects on roadway operation and circulation. Haul routes for the CHP Academy EIP are shown in Figure 4.7-1.

This analysis used estimated construction traffic generation (expressed as average trips per day) to develop a qualitative evaluation of short-term effects on the local and regional roadway in the project vicinity. Table 4.7-3 summarizes construction phase-related trips anticipated for the CHP Academy APA and CHP Academy Alternative B, which includes trips generated by trucks hauling away excavated materials, and trucks delivering construction equipment and materials. Daily truck trips required to haul away excavated spoils and import fill materials are estimated based on a typical capacity of 20 cubic yards per truck . Each truck and each work would generate two construction-related trips. A detailed list of construction equipment, construction areas, daily and total excavation, and daily total imported material for each phase are included in Appendix E.

The key effects were identified and evaluated based on the environmental characteristics of the CHP Academy EIP project area and the magnitude, intensity, and duration of activities related to the construction and operation of this project.

4.7.2.2 Determination of Effects

For this analysis, a transportation effect was considered significant if it would result in any of the following outcomes, which are based on professional practice, State CEQA Guidelines Appendix G, *City of West Sacramento General Plan Policy Document*, and the City's LOS policies:

- cause an increase in traffic that is substantial in relation to the existing traffic load and capacity of the street system (i.e., result in a substantial increase in the number of vehicle trips, the V/C ratio on roads, or congestion at intersections);
- cause, either individually or cumulatively, exceedance of a LOS standard established by the City and/or the California Department of Transportation (Caltrans) for designated roads or highways;
- substantially alter present patterns of circulation or movement;
- substantially increase hazards because of a design feature (e.g., sharp curves or dangerous intersections) or incompatible uses (e.g., slow-moving vehicles);
- result in inadequate emergency access;
- result in inadequate parking capacity; or

- conflict with adopted policies, plans, or programs supporting alternative transportation (e.g., bus turnouts, bicycle racks); or substantially impede navigation of watercraft as a result of the installation of cofferdams or the staging of barges within navigable sections of the surrounding waterways.

4.7.3 Effects and Mitigation Measures

4.7.3.1 No Action Alternative

The No Action Alternative represents the continuation of the existing deficiencies along the portion of the Sacramento Bypass Levee reach in the CHP Academy EIP project area. Under the No Action Alternative, there would be no change in the characteristics of the regional transportation system, local roadways, or navigation in the project area. It is likely that the levee roads and other roads in the program area would continue to be maintained by the City. No road modifications, including the raising and building of new roads, would occur, and navigation would not change under the No Action Alternative.

Because no levee improvements would be made under the No Action Alternative, the risk that the Sacramento Bypass Levee could fail due to seepage or slope stability or geometry issues would continue. Failure of the Sacramento Bypass Levee, depending on the magnitude of the event, could cause catastrophic flooding of the entire city of the magnitude described in the Transportation and Navigation program analysis (Section 3.5.3.3.1). In summary, those effects could include widespread damage to the city's utilities, roadways, railways, major interstate transportation corridors, and other infrastructure systems, interrupting emergency response services and hindering the region's and the state's abilities to move goods and people. However, the timing, duration and magnitude of a flood event are speculative and unpredictable, and therefore a precise determination of significance is not possible.

4.7.3.2 CHP Academy Applicant Preferred Alternative

Implementation of the CHP Academy APA would result in the following effects on transportation and navigation. A description of these effects is provided below the summary table. The CHP APA would avoid the UPRR tracks that run adjacent to the eastern end of the Sacramento Bypass Levee. Construction-related activities would not have an effect on its normal operations. Therefore, effects on railroads are not addressed further in this section.

Effect	Finding	With Mitigation	Mitigation Measure
TN-1: Temporary Increase in Traffic Volumes from Construction-Generated Traffic	Less than significant	N/A	N/A
TN-2: Temporary Road Closures or Restricted Access to Parking on the Levee Crown or Roads That Run Adjacent to the Levee	Less than significant	N/A	N/A
TN-3: Increase in Safety Hazards Attributable to Construction-Generated Traffic	Less than significant	N/A	N/A
TN-4: Increase in Emergency Response Times	Less than significant	N/A	N/A

Effect	Finding	With Mitigation	Mitigation Measure
TN-5: Inadequate Parking Supply to Meet Parking Demand for Construction Equipment and Construction Workers	Less than significant	N/A	N/A
TN-6: Disruption of Alternative Transportation Modes as a Result of Temporary Road Closures	Less than significant	N/A	N/A

The following detail for Effect TN-1 is specific to the CHP Academy APA and project site:

Effect TN-1: Temporary Increase in Traffic Volumes from Construction-Generated Traffic

Effect TN-1 would apply only to highways and surface streets in the CHP Academy EIP project area. Implementation of the CHP Academy APA would require hauling of construction equipment and materials to the CHP Academy EIP project area along major highways and through surface streets in the city.

The use of highways to haul construction equipment and materials to and from the CHP Academy EIP project area would increase daily traffic. Additionally, many of the construction-generated trips would involve slow-moving trucks, which would further affect highway traffic. However, the increase in AADT would be relatively small. With the addition of the maximum daily construction-generated traffic shown in Table 4.7-3 to the AADT counts in Table 4.7-1, the maximum increase in traffic along any of the segments of these highways would be 0.42%. This increase in AADT is not expected to significantly degrade the operation of highways near the project area.

Surface routes that would be used would be along Reed Avenue and Harbor Boulevard. Table 4.7-4 shows the existing ADT levels on the roads to be used as haul routes for the CHP Academy APA with the addition of the maximum daily construction-generated traffic shown in Table 4.7-3.

Table 4.7-4. Existing and Projected ADT on Haul Routes for the CHP Academy APA

Street	Limits	Existing ADT	Existing LOS	Max Trips/Day	ADT During Construction
North Harbor Blvd	Riverbank Rd to Reed Ave	4,529	A	356	4,885
North Harbor Blvd	City Limits to Riverbank Rd	4,801	A	356	5,157
Reed Ave	Riverside Pkwy to Sunset Ave	15,930	A	356	16,286

The construction traffic generated by the CHP Academy APA would temporarily increase the daily and peak hour traffic along specified routes shown in Table 4.7-4, which are operating well within the City's LOS standard. Traffic levels would return to normal levels once construction is completed. Although this addition of construction-related traffic would not be expected to degrade the LOS on haul route roads to an unacceptable level, slow-moving heavy trucks could affect traffic flow on these roadways, particularly if numerous trips occur during the morning or afternoon peak traffic periods. Implementation of the traffic control and road maintenance plan environmental commitment, described in Chapter 2, Alternatives, would reduce the effects of construction traffic along highways and surface streets to a less-than-significant level.

Effect TN-2: Temporary Road Closures or Restricted Access to Parking on the Levee Crown or Roads That Run Adjacent to the Levee

Implementation of the CHP APA will involve the use and maneuvering of large equipment that may require the adjacent Riverbank Road to be temporarily closed or reduce its usage to a single lane. Temporary road closures or reduction in use of the roads would require a detour of normal traffic to adjacent streets. The detouring of traffic would increase daily traffic quantities on roads in the surrounding areas. The environmental commitment to develop and implement a traffic control and road maintenance plan, as described in Section 2.9, in Chapter 2, Alternatives, would reduce this effect to a less than significant level.

Effect TN-3: Increase in Safety Hazards Attributable to Construction-Generated Traffic

The maneuvering of construction-related vehicles and equipment among the general-purpose traffic on Riverbank and other local roads could cause safety hazards. However, execution of the environmental commitment to develop and implement a traffic control and road maintenance plan, described in Section2.9 of Chapter 2, Alternatives, would minimize construction-related traffic hazards, and would reduce the intensity of this effect. This effect would be less than significant.

Effect TN-4: Increase in Emergency Response Times

Emergency access to the project vicinity could be affected by construction of the project, and construction-related traffic could delay or obstruct the movement of emergency vehicles. However, execution of the environmental commitment to develop and implement a traffic control and road maintenance plan, described in Section2.9 of Chapter 2, Alternatives, would minimize construction-related effects on emergency response times. This effect would be less than significant.

Effect TN-5: Inadequate Parking Supply to Meet Parking Demand for Construction Equipment and Construction Workers

A parking area for construction workers and trucks would be provided at staging areas adjacent to a work site or areas within the levee right-of-way; therefore, this effect would be less than significant.

Effect TN-6: Disruption of Alternative Transportation Modes as a Result of Temporary Road Closures

Although most of the construction of the proposed project would take place within the project right-of-way, temporary road closures may be needed in some areas, which could interfere with transit services or bicycle travel along these roads. Implementation of the Traffic Control and Road Maintenance Plan environmental commitment, described in Section2.9 of Chapter 2, Alternatives, would minimize construction-related traffic conflicts with alternative modes of transportation. Therefore, this effect would be less than significant. No mitigation is required.

4.7.3.3 CHP Academy Alternative B

Implementation of the CHP Academy Alternative B would result in the following effects on transportation and navigation. A description of these effects is provided below the summary table. The CHP Academy Alternative B would avoid the UPRR tracks that run adjacent to the eastern end of

the Sacramento Bypass Levee. Construction-related activities would not affect the normal operation of the tracks. Therefore, effects on railroads are not addressed further in this section.

Effect	Finding	With Mitigation	Mitigation Measure
TN-1: Temporary Increase in Traffic Volumes from Construction-Generated Traffic	Less than significant	N/A	N/A
TN-2: Temporary Road Closures or Restricted Access to Parking on the Levee Crown or Roads That Run Adjacent to the Levee	Less than significant	N/A	N/A
TN-3: Increase in Safety Hazards Attributable to Construction-Generated Traffic	Less than significant	N/A	N/A
TN-4: Increase in Emergency Response Times	Less than significant	N/A	N/A
TN-5: Inadequate Parking Supply to Meet Parking Demand for Construction Equipment and Construction Workers	Less than significant	N/A	N/A
TN-6: Disruption of Alternative Transportation Modes as a Result of Temporary Road Closures	Less than significant	N/A	N/A

Effect TN-1: Temporary Increase in Traffic Volumes from Construction-Generated Traffic

This effect on major highways in the project vicinity would be the same as described under the CHP APA, above. The maximum number of trips per day would be 278, rather than 356 as noted for the CHP APA, resulting in a maximum increase in traffic of 0.33% on highway segments near the project area.

This effect on surface streets in the project vicinity would be the same as described under the CHP APA, above. The maximum number of trips per day would be 278, rather than 356 as noted for the CHP APA. This effect is considered less than significant. No mitigation is required.

Effect TN-2: Temporary Road Closures or Restricted Access to Parking on the Levee Crown or Roads That Run Adjacent to the Levee

This effect would be the same as described under the CHP APA, above. This effect is considered less than significant. No mitigation is required.

Effect TN-3: Increase in Safety Hazards Attributable to Construction-Generated Traffic

This effect would be the same as described under the CHP APA, above. This effect is considered less than significant. No mitigation is required.

Effect TN-4: Increase in Emergency Response Times

This effect would be the same as described under the CHP APA, above. This effect is considered less than significant. No mitigation is required.

Effect TN-5: Inadequate Parking Supply to Meet Parking Demand for Construction Equipment and Construction Workers

This effect would be the same as described under the CHP APA, above. This effect is considered less than significant. No mitigation is required.

Effect TN-6: Disruption of Alternative Transportation Modes as a Result of Temporary Road Closures

This effect would be the same as described under the CHP APA, above. This effect is considered less than significant. No mitigation is required.

Section 4.8

Air Quality and Climate Change—CHP Academy Early Implementation Project

4.8.1 Affected Environment

This section describes the affected environment for air quality and climate change in the CHP Academy EIP project area, including the regulatory and environmental settings.

4.8.1.1 Air Quality Regulatory Setting

4.8.1.1.1 Federal

The following Federal policies related to air quality may apply to the implementation of the CHP Academy EIP. Please see the program information in Section 3.6.2.1, Air Quality Regulatory Setting, for a more complete description of each policy.

- Clean Air Act
- General Conformity Regulation
- Federal Tailpipe Emission Standards

4.8.1.1.2 State

The following state policies or agencies related to air quality may apply to the implementation of the CHP Academy EIP. Please see Section 3.6.2.1, Air Quality Regulatory Setting, for a more complete description of each policy.

- California Clean Air Act
- Idling Limit Regulation
- Airborne Toxic Control Measure
- State Tailpipe Emission Standards
- State NO_X Reduction Program

4.8.1.1.3 Local

The following state policies or agencies related to air quality and climate change may apply to the implementation of the CHP Academy EIP. Please see Section 3.6.2.1, Regulatory Setting, for a more complete description of each policy.

- Yolo-Solano Air Quality Management District
- Sacramento Metropolitan Air Quality Management District

4.8.1.2 Climate Change Regulatory Setting

4.8.1.2.1 Federal

The following Federal policies related to climate change may apply to the implementation of the CHP Academy EIP. Please see the program information in Section 3.6.2.2, Climate Change Regulatory Setting, for a more complete description of each policy.

- Mandatory Greenhouse Gas Reporting Rule
- Environmental Protection Agency Endangerment cause and Contribute Findings

4.8.1.2.2 State

The following state policies or agencies related to climate change may apply to the implementation of the CHP Academy EIP. Please see Section 3.6.2.2, Climate Change Regulatory Setting, for a more complete description of each policy.

- Executive Order S-3-05
- Assembly Bill 32, California Climate Solutions Act of 2006
- Senate Bill 97
- Actions Taken by California Attorney General's Office
- California Air Pollution Control Officers Association Guidance
- Executive Order S-13-08

4.8.1.3 Air Quality Environmental Setting

The environmental setting for the CHP Academy EIP is described in the Program Area Affected Environment. The following provides a summary of air quality and climate change information relevant to air quality in the proposed CHP Academy EIP project area.

4.8.1.3.1 Study Area

The study area is in Yolo County, which is located in the Sacramento Valley Air Basin (SVAB). The SVAB includes Sacramento, Shasta, Tehama, Butte, Glenn, Colusa, Sutter, Yuba, Yolo, and parts of Solano and Placer Counties. The SVAB is bounded on the north by the Cascade Range, on the south by the San Joaquin Valley Air Basin, on the east by the Sierra Nevada, and on the west by the Coast Range.

4.8.1.3.2 Background Information on Air Pollutants

Air quality studies generally focus on five pollutants most commonly measured and regulated, and referred to as criteria air pollutants: ozone, CO, inhalable PM (PM10 and PM2.5), NO_2, and SO_2. Because ozone, a photochemical oxidant, is not emitted into the air directly from sources, emissions of ozone precursors, including NO_X and ROG, are regulated with the aim of reducing ozone formation in the lowermost region of the troposphere.

Ozone and NO_2 are considered regional pollutants because they (or their precursors) affect air quality on a regional scale: NO_2 reacts photochemically with ROG to form ozone, and this reaction

occurs at some distance downwind of the source of pollutants. Pollutants such as CO, PM10, and PM2.5 are considered to be local pollutants because they tend to disperse rapidly with distance from the source.

The principal characteristics surrounding these pollutants and TACs and GHGs are discussed in Section 3.6.2.2.2, Background Information on Air Pollutants.

4.8.1.3.3 Air Quality Attainment Status

The air quality attainment status for criteria pollutants in Yolo County and Sacramento County are summarized in Table 4.8-1. Areas are classified as in attainment or in non-attainment with respect to CAAQS and NAAQS. These classifications are made by comparing actual monitored air pollutant concentrations to state and Federal standards. If a pollutant concentration is lower than the state or Federal standard, the area is considered to be in attainment of the standard for that pollutant. If pollutant levels exceed a standard, the area is considered a non-attainment area. If data are insufficient to determine whether a pollutant is violating the standard, the area is designated as unclassified. This typically occurs in non-urbanized areas, where pollutant levels may be less closely monitored.

On December 22, 2008, EPA classified Yolo County as a partial non-attainment area for the PM2.5 standard. With the new designation, an attainment plan will be submitted to EPA by 2012.

Table 4.8-1. Yolo County and Sacramento County Air Quality Attainment Status

Pollutant	Averaging Time	State Standards	National Standards
Yolo County			
Ozone	1-Hour	Serious Non-attainment	No Designation
	8-Hour	Non-attainment	Serious Non-attainment
CO		Attainment	Attainment
PM10	24-Hour	Non-attainment	Unclassified
PM2.5	24-Hour	Unclassified	Partial Non-attainment
Sacramento County			
Ozone	1-Hour	Serious Non-attainment	No Designation
	8-Hour	Non-attainment	Serious Non-attainment
CO		Attainment	Attainment
PM10	24-Hour	Non-attainment	Moderate Non-attainment
PM2.5	24-Hour	Non-attainment	Unclassified/Attainment

Source: California Air Resources Board 2009c.

4.8.1.3.4 Sensitive Receptors

Sensitive land uses in the vicinity of the CHP Academy EIP project area are primarily agriculture and public open space. The CHP Academy is the only employer that has facilities that lie within, or adjacent to, the project area. No sensitive land uses are identified within 500 feet of the project site.

4.8.1.4 Climate Change Environmental Setting

The environmental setting for the CHP Academy EIP is described in the Program Area Affected Environment. The following provides a summary of climate change information relevant to the proposed CHP Academy EIP project area.

4.8.1.4.1 Background Information on Climate Change

GHGs are any gasses that absorb infrared radiation in the atmosphere. Increases in these gasses lead to more absorption of radiation and warm the lower atmosphere further, thereby increasing evaporation rates and temperatures near the surface. Emissions of GHGs in excess of natural ambient concentrations are thought to be responsible for the global climate change. The most common GHG is CO_2, which constitutes approximately 84% of all emissions of GHG in California. GHG are global pollutants, unlike criteria air pollutants (such as ozone precursors) and TACs, which are pollutants of regional and local concern.

4.8.1.4.2 California Climate Trends

Maximum (daytime) and minimum (nighttime) temperatures are increasing almost everywhere in California but at different rates. The annual minimum temperature averaged over all of California increased 0.33° F per decade from 1920 to 2003, while the average annual maximum temperature increased 0.1° F per decade (Moser et al. 2009). At the same time the precipitation mix between snow and rain has shifted in favor of more rainfall and less snow (Mote et al. 2005; Knowles 2006). These changes have significant implications for water supply, flooding, aquatic ecosystems, energy generation, and recreation throughout the state.

4.8.2 Air Quality Environmental Consequences

This section describes the environmental consequences relating to air quality for the proposed CHP Academy EIP. It describes the methods used to determine the effects of the project and lists the thresholds used to conclude whether an effect would be significant. The effects that would result from implementation of CHP Academy EIP project, findings with or without mitigation, and applicable mitigation measures are presented in a summary table. These effects tier from the program analysis effects described in Section 3.6.3.3, Effects and Mitigation Measures.

4.8.2.1 Air Quality Assessment Methods

To assist in the determination of effects, various quantitative models are available to predict emissions and particulate matter generation. Two such models are URBEMIS and SacRCEM. While SacRCEM has typically been used for other recent levee improvement projects in the Sacramento Valley, both models have been applied to simulate the project-level air quality effects of the WSLIP. Given the similarity in the architecture of the two models, for ROG, NO_X, and CO_2, the outputs from the two models are very similar and any variance is considered not statistically significant. For PM, the URBEMIS outputs are considered more conservative (meaning the production values are higher) based on the model's internal methods and assumptions for treatment of earthwork. As the project proponent, WSAFCA has selected this more conservative approach to not under-predict potential project effects. URBEMIS further allows application of mitigation measures to fine-tune and predict

quantitative effectiveness of available measures and assist in determining post-mitigation findings. For these reasons, WSAFCA has selected to use the results of URBEMIS for quantitative determination of effects, effect findings, and mitigation efficacy. The results of both models for the WSLIP EIPs are in Appendix E.

Construction-related emissions were estimated using URBEMIS 2007 model (Version 9.2.4), which uses EPA, CARB, and air district emissions factors to estimate emissions from construction activities. Construction emissions (tailpipe emissions and fugitive dust) were modeled using the conceptual construction schedule, phases, and equipment usage based on the most current available project design information.

4.8.2.2 Air Quality Determination of Effects

For this analysis, an effect pertaining to air quality was analyzed based on professional practice and State CEQA Guidelines Appendix G (14 CCR 15000 *et seq*.). An effect was considered significant if it would:

- conflict with, or obstruct implementation of, the applicable air quality plan;
- violate any air quality standard or substantial contribution to existing or projected air quality violation;
- result in a cumulatively considerable net increase of any criteria pollutant for which the project region is a non-attainment area under NAAQS and CAAQS;
- expose sensitive receptors to substantial pollutant concentrations; or
- create objectionable odors affecting a substantial number of people.

The appropriate district-recommended emission thresholds as published in their respective CEQA guidance documents also apply to individual projects under their jurisdiction. An air quality effect is considered to be significant if the project's construction emissions would exceed the General Conformity thresholds (see Section 3.6.2.1.1, General Conformity Regulation). For portions of the construction and operational activities that would occur in Yolo County, an air quality effect is considered to be significant if the air pollutant emissions would exceed YSAQMD's thresholds of significance as shown in Table 3.6-2 (see Section 3.6.2.1, Regulatory Setting). For portions of the construction activities that would occur in Sacramento County (i.e., haul trucks and commute vehicles traveling on public roads in the County), an air quality effect is considered to be significant if the air pollutant emissions would exceed SMAQMD's thresholds of significance as shown in Table 3.6-3 (see Section 3.6.2.1, Regulatory Setting).

4.8.3 Air Quality Effects and Mitigation Measures

4.8.3.1 No Action Alternative

The No Action Alternative represents the continuation of the existing deficiencies along the portion of the Sacramento Bypass Levee reach in the CHP Academy EIP project area. Current levee operations and maintenance activities would continue, but there would be no construction-related emissions from program implementation or maintenance.

Because no levee improvements would be made under the No Action Alternative, the risk that the Sacramento Bypass Levee could fail due to seepage or slope stability or geometry issues would continue. Failure of the Sacramento Bypass Levee, depending on the magnitude of the event, could cause catastrophic flooding of the entire city of the magnitude described in the Air Quality program analysis (Section 3.6.3.3.1). In summary, those effects on air quality could include emission of pollutants in excess of air quality standards, increase in GHG emission, and exposure of sensitive receptors to toxic air emissions as a result of flood-fighting activities. These effects could occur for days, weeks or even months. These effects could be considered significant; however, the timing, duration, and magnitude of a flood event are speculative and unpredictable, and therefore a precise determination of significance is not possible

4.8.3.2 CHP Academy Applicant Preferred Alternative

Implementation of the CHP Academy APA would result in the effects on air quality as outlined in the summary table provided after construction phases and duration information on air quality and climate change. A description of these effects is provided below the summary table.

Construction phases, duration, and activities for CHP Academy APA are listed in Table 4.8-2. As described in Chapter 2, Alternatives, construction of the proposed project is anticipated to take place in 2011 and would be completed during the typical construction season. For the air quality effect analysis, it is assumed that the construction work would occur progressively by phases. For each construction phase, construction equipment uses at the site, exported spoils, and imported materials are provided by the project engineers and summarized in Table 4.8-2. Detailed operation hours and horsepower ratings of construction equipment used for each construction phase and URBEMIS model results are included in Appendix E.

Table 4.8-2. Construction Phases, Schedule, and Activities: CHP Academy APA

Phase	Duration (days)	Area (acres)	Excavated Spoils (cy)	Import Material (cy)	Construction Equipment
Flood Control					
Clearing and grubbing	9	14.3	20,266	–	12 dump trucks, 2 bulldozers, 1 excavator
Concrete removal	7	1.9	1,018	–	4 dump trucks, 1 loader, 2 excavators
Levee degrade and slope flattening	26	4.3	59,374	–	12 dump trucks, 1 bulldozer, 1 excavator
Slurry wall construction	29	–	29,260	500	2 dump trucks, 1 loader, 1 bulldozer, 1 long reach track hoe, 1 rough terrain forklifts
Fill placement	27	4.3	–	79,600	14 dump trucks, 4 bulldozers, 1 excavator, 2 sheepsfoot compactors, 2 maintainers, 1 water truck
Concrete placement	24	1.9	–	1,018	5 concrete trucks, 1 crane

Phase	Duration (days)	Area (acres)	Excavated Spoils (cy)	Import Material (cy)	Construction Equipment
Recreation					
Grading	8	1.7	–	–	1 scraper, 1 wheel loader, 1 motor grader, 1 dump truck, 1 steel wheel loader, 1 water truck
Install pathways and signs	12	1.3	–	1,850	1 dump truck, 1 asphalt paver, 1 asphalt sealer, 1 striping truck, 1 small front loader, 1 skid steer loader, 1 small roller

cy = cubic yards.

Based on the construction activities described above, construction-related emissions were estimated using the URBEMIS 2007 model. It is anticipated that on-site equipment operations would generate the highest daily diesel exhaust and site earthmoving activities would result in the highest daily fugitive dust generation. The estimated construction emissions are shown in Table 4.8-3. To comply with YSAQMD, SMAQMD, and General Conformity thresholds, annual emissions are estimated for ROG, NOX, CO, PM10, and PM2.5 and the maximum daily emission is estimated for NOX and PM10. It is assumed that half of delivery trucks and construction workers would come from the YSAQMD and the other half of trucks and commute vehicles would come from the SMAQMD. Detailed construction emissions for each construction phase are summarized in Appendix E.

Table 4.8-3. Estimated Construction Emissions: CHP Academy APA

Construction Emissions	ROG (tons/year)	NO_X (lbs/day)	NO_X (tons/year)	CO (tons/year)	PM10 (lbs/day)	PM10 (tons/year)	PM2.5 (tons/year)	CO2 (tons/year)
Project Construction without Mitigations								
Project-wide								
Maximum daily emissions	–	371	–	–	369	–	–	–
Total annual Emissions	1.2	–	11.1	4.2	–	13.9	3.2	1,290
Within YSAQMD								
Maximum daily emissions	–	325	–	–	367	–	–	–
Total annual Emissions	1.1	–	9.8	3.6	–	13.8	3.2	1,115
Within SMAQMD								
Maximum daily emissions	–	46	–	–	2	–	–	–
Total annual emissions	0.1	–	1.3	0.6	–	0.1	0.1	174
Project Construction with Mitigations								
Project-wide								
Maximum daily emissions	–	253	–	–	45	–	–	–
Total annual emissions	1.2	–	7.5	4.2	–	3.1	0.8	1,290
Within YSAQMD								
Maximum daily emissions	–	207	–	–	43	–	–	–
Total annual emissions	1.1	–	6.2	3.6	–	3	0.7	1,115
Within SMAQMD								
Maximum daily emissions	–	46	–	–	2	–	–	–
Total annual emissions	0.1	–	1.3	0.6	–	0.1	0.1	174
Construction Thresholds								
Federal General Conformity (Project-wide emissions)	50	–	50	–	–	100	100	–
YSAQMD (Emissions in YSAQMD)	10	–	10	–	80	–	–	–
SMAQMD (Emissions in SMAQMD)	–	85	–	–	–	–	–	–

Effect	Finding	With Mitigation	Mitigation Measure
AQ-1: Conflict with or Obstruct an Applicable Air Quality Plan	Less than significant	N/A	N/A
AQ-2: Increase in Construction Emissions to Exceed Applicable Thresholds	Significant	Less than significant to significant and unavoidable	AQ-MM-1: Implement Measures to Reduce Exhaust Emissions of NO_X and ROG if Unmitigated Emissions Exceed NO_X and ROG Thresholds AQ-MM-2: Implement Fugitive Dust Control Plan If Unmitigated Emissions Exceed PM10 or PM 2.5 Thresholds AQ-MM-3: Provide Advance Notification of Construction Schedule and 24-Hour Hotline to Residents AQ-MM-4: Pay Required Fees to the SMAQMD to Offset NO_X Emissions
AQ-3: Long-Term Operation and Maintenance Emissions of ROG, NO_X, and PM10	Less than significant	N/A	N/A
AQ-4: Exposure of Sensitive Receptors to Toxic Air Emissions	Less than significant	N/A	N/A
AQ-5: Exposure to Objectionable Odors from Diesel Exhaust	Less than significant	N/A	N/A

As described in Chapter 2, Alternatives, in order to complete the project before the flood season, the contractors would be allowed to construct on a 24/7 work schedule. Depending on the daily construction activities, the 24/7 work schedule could result in higher daily NO_X and PM10 emissions than the estimated emissions shown in Table 4.8-3, which are based on the standard construction schedule (10 hours per day and 5 days per week). The annual emissions for ROG, NO_X, CO, PM10, and PM2.5 would be the same for both the standard schedule and the 24/7 schedule because the project would be completed in 2011 under either schedule.

Effect AQ-1: Conflict with or Obstruct an Applicable Air Quality Plan

A project is deemed inconsistent with an air quality plan if it would result in population or employment growth that exceeds the growth estimates in the applicable air quality plan—thus generating emissions not accounted for in the applicable air quality plan emissions budget. Consequently, proposed programs need to be evaluated to determine whether they would generate population and employment growth and, if so, whether that growth would exceed the growth rate included in the relevant air quality plan.

As described in Chapter 6, Growth-Inducing and Cumulative Effects, the implementation of the overall WSLIP (including this project) might remove an obstacle for undeveloped lands in West Sacramento and make development easier or more attractive for these lands, which might result in population growth in these areas in the long term. The City is currently in the process of updating its 1994 General Plan. It is expected that the new General Plan will include the land use changes in these areas. Additionally, the 2035 Metropolitan Transportation Plan (Sacramento Area Council of Government 2008) has included the population projection of 278,786 people for Yolo County and

87,402 people for West Sacramento, which has accounted for the land development and population growth of these areas through 2035. The air quality conformity analysis as part of the 2035 Metropolitan Transportation Plan meets the emission conformity test for the Sacramento ozone non-attainment area. Therefore, the overall WSLIP and this project would not conflict with or obstruct the implementation of air quality plans. This effect would be less than significant. No mitigation is required.

Effect AQ-2: Increase in Construction Emissions to Exceed Applicable Thresholds

Without mitigation, construction-related emissions under the CHP Academy APA would exceed YSAQMD's emission thresholds for NO_X and PM10 and would result in a significant effect. Mitigation measures for this effect are AQ-MM-1 to AQ-MM-3, described below. Table 4.8-3 shows the NO_X and PM10 emissions with these mitigation measures. After mitigation, the NO_X and PM10 emissions would be less than YSAQMD's significance thresholds.

The 24/7 work schedule could result in higher daily NO_X and PM10 emissions than the standard schedule, depending on the daily construction activities. The implementation of AQ-MM-2, which includes all applicable and feasible fugitive dust control measures required by YSAQMD, would reduce PM10 emissions below the YSAQMD's significance threshold. The implementation of AQ-MM-4, which includes the NO_X mitigation fee required by the SMAQMD, would reduce NO_X emissions below the SMAQMD's significance threshold.

It is possible the CHP Academy EIP could be constructed simultaneously with The Rivers EIP. Depending on whether the APA or Alternative B for each project is constructed at the same time, it is possible the combined emissions from the simultaneous projects could exceed the annual average YSCAQMD threshold for NO_X and/or the maximum daily SMAQMD threshold for NO_X. In either case, mitigation measure AQ-MM-1 would be implemented. SMAQMD's requirement for NO_X offset purchases would reduce the impact in Sacramento County to less than significant. However, YSAQMD does not require purchase of offsets, so after implementation of the mitigation measure the impact of simultaneous projects could still be significant and unavoidable in Yolo County.

Mitigation Measures

Mitigation Measure AQ-MM-1: Implement Measures to Reduce Exhaust Emissions of NO_X and ROG if Unmitigated Emissions Exceed NO_X and ROG Thresholds

Unmitigated NO_X and ROG emissions from construction equipment tailpipes could potentially exceed the YSAQMD CEQA thresholds. Therefore, WSAFCA will require the construction contractor to implement feasible and reasonable measures to reduce public nuisance and tailpipe emissions from diesel-powered construction equipment. This requirement will be incorporated into the construction contracts.

Depending on the exceedance amounts of NO_X and ROG emissions, the WSAFCA will require the construction contractor to implement either or both of the following mitigation options.

Mitigation Measure AQ-MM-1a

According to the YSAQMD guidelines (Yolo-Solano Air Quality Management District 2007), the project lead agency is encouraged to explore and incorporate mitigation measures as technology advances and less emissive products become available at lower costs.

The measures recommended by the YSAQMD are listed below.

- Reduce use, trips, and unnecessary idling of heavy equipment. Shut down idling equipment that is not used for more than 5 consecutive minutes as required by California law.
- Maintain all construction equipment in proper tune according to manufacturer's specifications.
- Use a modern equipment fleet meeting CARB's 1996 or newer certification standard for off-road heavy-duty diesel engines.
- Install emission control devices on older equipment to reduce CO, ROG, and NO_X emissions to levels equivalent to CARB's 1996 or newer certification standard.
- Locate stationary diesel-powered equipment and haul truck staging areas as far as practicable from sensitive receptors.
- Use existing power sources (e.g., power lines) or clean fuel generators rather than conventional diesel generators, when feasible
- Substitute gasoline-powered for diesel-powered equipment when feasible.
- Use reformulated and emulsified diesel fuels where feasible.
- Use alternatively fueled construction equipment on site where feasible, such as compressed natural gas (CNG), liquefied natural gas (LNG), propane, or biodiesel.
- Use aqueous diesel fuel where feasible.
- Use CARB and/or EPA-verified particulate traps and other appropriate controls (i.e. diesel oxidation catalyst or diesel particular filters) where feasible to reduce emissions of NO_X, diesel particulate, and other pollutants at the construction site.

Mitigation Measure AQ-MM-1b

In addition to above measures, the construction contractor could provide a plan, for approval by WSAFCA and YSAQMD, demonstrating that the heavy-duty off-road equipment to be used at the project sites, including owned, leased, and subcontractor equipment, will achieve a project-wide fleet-average reduction of 20% for NO_X and 45% for diesel particulate, compared to the most recent CARB fleet average at time of construction. A construction mitigation calculator may be downloaded from the SMAQMD web site to perform the fleet average evaluation (Sacramento Metropolitan Air Quality Management District 2009).

Mitigation Measure AQ-MM-2: Implement Fugitive Dust Control Plan if Unmitigated Emissions Exceed PM10 or PM 2.5 Thresholds

The construction contractor will implement all applicable and feasible fugitive dust control measures required by YSAQMD including those listed below. This requirement will be incorporated into the construction contract.

- Post a publicly visible sign with the telephone number and person to contact regarding dust complaints. This person would respond and take corrective action within 48 hours. The phone number of YSAQMD also will be visible to ensure compliance with the YSAQMD Rule 2.5, Nuisance.
- Water active unpaved areas at all construction sites at least twice daily in dry conditions, with the frequency of watering based on the type of operation, soil, and wind exposure.

- Prohibit all grading activities and water all areas of disturbed soil under windy conditions (more than 20 miles per hour).
- Limit on-site vehicles to a speed that prevents visible dust emissions to extend beyond unpaved roads.
- Cover all trucks hauling dirt, sand, or loose materials.
- Cover active and inactive storage piles where appropriate.
- Cover or hydroseed unpaved areas that will remain inactive for extended periods.
- Apply soil stabilizers to active and inactive areas where appropriate.
- Install wheel washers at the entrance to construction sites for all exiting trucks.
- Sweep streets if visible soil material is carried out from the construction site.
- Install wind fencing and phase grading operations where appropriate.

Fugitive dust emissions from the construction of the project would be reduced to a less-than-significant level with the implementation of above mitigation.

Mitigation Measure AQ-MM-3: Provide Advance Notification of Construction Schedule and 24-Hour Hotline to Residents

WSAFCA will provide advance written notification of the proposed construction activities to all residences and other air quality-sensitive uses within 500 feet of the construction site. Notification will include a brief overview of the proposed project and its purpose, as well as the proposed construction activities and schedule. It will also include the name and contact information of WSAFCA's project manager or a representative for ensuring that reasonable measures are implemented to address the problem.

Mitigation Measure AQ-MM-4: Pay Required Fees to the SMAQMD to Offset NO_X Emissions

It is possible that on-road construction emissions, for vehicles traveling within the Sacramento County, could exceed the SMAQMD NO_X threshold. If on-road construction emissions exceed SMAQMD threshold levels, WSAFCA will be required to pay an offsite mitigation fee. Prior to the approval of project plans or the issuance of grading permits, the WSAFCA will submit proof that the offsite air quality mitigation fee of $16,000 per ton of NO_X has been paid to SMAQMD and that the construction air quality mitigation plan has been approved by SMAQMD and the lead agency. SMAQMD already has enacted a well-defined program to use NO_x offset fees received from applicants to fund regional NO_x emission reduction projects. Therefore, with the implementation of this mitigation, the air quality impact to SMAQMD would be reduced to a less-than-significant level.

Effect AQ-3: Long-Term Operation and Maintenance Emissions of ROG, NO_X, and PM10

After the project is constructed, the facilities will be generally maintained as needed. Maintenance work would be less extensive and would take place over a few days per year. In addition, maintenance and operational activities are part of the existing environmental baseline and thus would not create a substantial source of new emissions. This effect would be less than significant. No mitigation is required.

Effect AQ-4: Exposure of Sensitive Receptors to Toxic Air Emissions

Construction of the proposed project would result in short-term diesel exhaust emissions from on-site heavy duty equipment. Particulate exhaust emissions from diesel-fueled engines (DPM) were identified as a TAC by CARB in 1998. Construction of the project would result in the generation of DPM emissions from the use of off-road diesel equipment required for site grading and excavation, paving, and other construction activities.

The assessment of health risks associated with exposure to diesel exhaust typically is associated with chronic exposure, in which a 70-year exposure period is often assumed. However, while cancer can result from exposure periods of less than 70 years, acute exposure periods (i.e., exposure periods of 2 to 3 years) to diesel exhaust are not anticipated to result in an increased health risk, as health risks associated with exposure to diesel exhaust are typically seen in exposures periods that are chronic. Construction of the project is not expected to take place at the same construction site for more than 1 to 2 years and would be expected to use a limited number of pieces of heavy equipment at the same construction site.

Furthermore, as required by CARB regulation, no in-use off-road diesel vehicles may idle for more than 5 consecutive minutes. In addition, implementation of Mitigation Measure AQ-MM-1 would further reduce exhaust emissions during construction. With implementation of mitigation measures and best management practices, the effect would be reduced to less than significant and no further mitigation is required.

Effect AQ-5: Exposure to Objectionable Odors from Diesel Exhaust

The proposed project would not result in any major sources of odor, nor would it involve operation of any of the common types of facilities that are known to produce odors (e.g., landfill, wastewater treatment facility). In addition, odors associated with diesel exhaust from the use of on-site construction equipment would be intermittent and temporary and would dissipate rapidly from the source with an increase in distance.

Furthermore, as required by CARB regulation, no in-use off-road diesel vehicles may idle for more than 5 consecutive minutes. Implementation of Mitigation Measures AQ-MM-1 and AQ-MM-3 would further reduce exhaust emissions during construction. This effect would be less than significant. No mitigation is required.

4.8.3.3 CHP Academy Alternative B

Implementation of the CHP Academy Alternative B would result in the following effects on air quality. A description of these effects is provided below the summary table.

Table 4.8-4 summarizes the construction phases, duration, and activities for CHP Academy Alternative B. As described in Chapter 2, Alternatives, construction of the proposed project is anticipated to take place in 20110 and would be completed during the typical construction season. For the air quality effect analysis, it is assumed that the construction work would occur progressively by phases. For each construction phase, construction equipment uses at the site, exported spoils, and imported materials are provided by the project engineers and summarized in Table 4.8-4. Detailed operation hours and horsepower ratings of construction equipment used for each construction phase are included in Appendix E.

As described in Chapter 2, Alternatives, in order to complete the project before the flood season, the contractors would be allow to construct on a 24/7 work schedule. Depending on the daily construction activities, the 24/7 work schedule could result in higher daily NO_X and PM10 emissions than the estimated emissions shown in Table 4.8-4, which are based on the standard construction schedule (10 hours per day and 5 days per week). The annual emissions for ROG, NO_X, CO, PM10, and PM2.5 would be the same for both the standard schedule and the 24/7 schedule because the project would be completed in 2011 under either schedule.

Table 4.8-4. Construction Phases, Activities, Schedule, and Equipment: CHP Academy Alternative B

Phase	Duration (days)	Area (acres)	Excavated Spoils (cy)	Import Material (cy)	Construction Equipment
Flood Control Alternative					
Clearing and grubbing	4	3.07	8,865	–	12 dump trucks, 2 bulldozers, 1 excavator
Excavate stability berm	5	1.48	11,054	–	4 dump trucks, 2 bulldozers, 1 excavator
Install stability berm and drain system	31	1.48	–	7,065	11 dump trucks, 2 bulldozers, 1 excavator, 1 sheepsfoot compactor, 1 maintainer, 1 water truck
Install relief wells	22	1.59	–	500	1 drill rig, 1 crane
Recreation Alternative					
Grading	8	1.7	–	–	1 scraper, 1 wheel loader, 1 motor grader, 1 dump truck, 1 steel wheel loader, 1 water truck
Install pathways and signs	12	1.3	–	1,850	1 dump truck, 1 asphalt paver, 1 asphalt sealer, 1 striping truck, 1 small front loader, 1 skid steer loader, 1 small roller

cy = cubic yards.

Based on the construction activities described above, construction-related emissions were estimated using the URBEMIS 2007 model. The estimated construction emissions are shown in Table 4.8-5. Detailed construction emissions for each construction phase are summarized in Appendix E.

Table 4.8-5. Estimated Construction Emissions: CHP Academy Alternative B

Construction Emissions	ROG (tons/year)	NO_X (lbs/day)	NO_X (tons/year)	CO (tons/year)	PM10 (lbs/day)	PM10 (tons/year)	PM2.5 (tons/year)	CO2 (tons/year)

SMAQMD (Emissions in SMAQMD)	–	85	–	–	–	–	–	–

Effect	Finding	With Mitigation	Mitigation Measure
AQ-1: Conflict with or Obstruct an Applicable Air Quality Plan	Less than significant	N/A	N/A
AQ-2: Increase in Construction Emissions to Exceed Applicable Thresholds	Significant	Less than significant – Significant and unavoidable	AQ-MM-1: Implement Measures to Reduce Exhaust Emissions of NO_X and ROG if Unmitigated Emissions Exceed NO_X and ROG Thresholds AQ-MM-2: Implement Fugitive Dust Control Plan If Unmitigated Emissions Exceed PM10 or PM2.5Thresholds AQ-MM-3: Provide Advance Notification of Construction Schedule and 24-Hour Hotline to Residents AQ-MM-4: Pay Required Fees to the SMAQMD to Offset NO_X Emissions
AQ-3: Long-Term Operation and Maintenance Emissions of ROG, NO_X, and PM10	Less than significant	N/A	N/A
AQ-4: Exposure of Sensitive Receptors to Toxic Air Emissions	Less than significant	N/A	N/A
AQ-5: Exposure to Objectionable Odors from Diesel Exhaust	Less than significant	N/A	N/A

Effect AQ-1: Conflict with or Obstruct an Applicable Air Quality Plan

This effect is the same as described above under the CHP Academy APA. The effect is considered less than significant. No mitigation is required.

Effect AQ-2: Increase in Construction Emissions to Exceed Applicable Thresholds

Without mitigation, construction-related emissions under the CHP Academy Alternative B may exceed YSAQMD's emission threshold for PM10 and would result in a significant effect. Mitigation measures for this effect are AQ-MM-2 and AQ-MM-3, described above under the CHP APA. Table 4.8-5 shows the mitigated PM10 emissions with the above fugitive dust control measures. After mitigation, the controlled PM10 emissions would be less than YSAQMD's 80 pounds/day significance threshold.

The 24/7 work schedule could result in higher daily NO_X and PM10 emissions than the standard schedule, depending on the daily construction activities. The implementation of AQ-MM-2, which includes all applicable and feasible fugitive dust control measures required by YSAQMD, will reduce PM10 emissions below the YSAQMD's significance threshold. The implementation of AQ-MM-4, described above under CHP Academy APA, which includes the NO_X mitigation fee required by the SMAQMD, would reduce NO_X emissions below the SMAQMD's significance threshold.

It is possible the CHP Academy EIP could be constructed simultaneously with The Rivers EIP. Depending on whether the APA or Alternative B for each project is constructed at the same time, it is possible the combined emissions from the simultaneous projects could exceed the annual average

YSCAQMD threshold for NO_X and/or the maximum daily SMAQMD threshold for NO_X. In either case, mitigation measure AQ-MM-1 would be implemented. SMAQMD's requirement for NO_X offset purchases would reduce the impact in Sacramento County to less than significant. However, YSAQMD does not require purchase of offsets, so after implementation of the mitigation measure the impact of simultaneous projects could still be significant and unavoidable in Yolo County.

Effect AQ-3: Long-Term Operation and Maintenance Emissions of ROG, NO_X, and PM10

This effect is the same as described above under the CHP Academy APA. The effect is considered less than significant. No mitigation is required.

Effect AQ-4: Exposure of Sensitive Receptors to Toxic Air Emissions

This effect is the same as described above under the CHP Academy APA. The effect is considered less than significant. No mitigation is required.

Effect AQ-5: Exposure to Objectionable Odors from Diesel Exhaust

This effect is the same as described above under the CHP Academy APA. The effect is considered less than significant. No mitigation is required.

4.8.4 Climate Change Environmental Consequences

This section describes the environmental consequences relating to climate change for the proposed CHP Academy EIP. It describes the methods used to determine the effects of the project and lists the thresholds used to conclude whether an effect would be significant. The effects that would result from implementation of CHP Academy EIP project, findings with or without mitigation, and applicable mitigation measures are presented in a summary table. These effects tier from the program analysis effects described in Section3.6.3.6, Effects and Mitigation Measures.

4.8.4.1 Climate Change Assessment Methods

Almost all increased GHG emissions associated with the proposed project would be generated by construction-related activities. Therefore, the focus of the GHG analysis is to evaluate construction-related emissions. The principal source of GHG associated with would be temporary tailpipe emissions from construction equipment and haul trucks; the principal GHG produced would be CO_2. No air district in California, including YSAQMD, has formally adopted a significant threshold for analyzing GHG or CO_2 emissions generated by a proposed project or a methodology for analyzing air quality effects related to global warming. However, CARB and the major air quality agencies in the state (Bay Area Air Quality Management District [BAAQMD], South Coast Air Quality Management District [SCAQMD] and San Joaquin Valley Air Pollution Control District [SJVAPCD]) have published draft thresholds for defining the significance of GHG emissions from construction projects and operational projects. Those draft thresholds and mitigation measures were utilized in the analysis of effects related to climate change.

To assist in the determination of effects, various quantitative models are available to predict emissions; URBEMIS and SacREM. As described in Section 3.6.3.1, Air Quality Assessment Methods,

those two models were utilized for quantitative determination of effects, effect findings, and mitigation efficacy.

4.8.4.2 Climate Change Determination of Effects

For this analysis, an effect pertaining to air quality was analyzed based on professional practice, draft NEPA Guidance published by CEQ, and State CEQA Guidelines Appendix G (14 CCR 15000 *et seq*.). An effect was considered significant if it would:

- generate GHG emission that may have a significant impact on the environment;
- conflict with an applicable plan adopted for the purpose of reducing GHG emissions.

4.8.5 Climate Change Effects and Mitigation Measures

4.8.5.1 No Action Alternative

The No Action Alternative is the same as that described above in Section 4.8.2.4. Air Quality No Action.

4.8.5.2 CHP Academy Applicant Preferred Alternative

Implementation of the CHP Academy APA would result in the effects on climate change as outlined in the summary table provided. A description of these effects is provided below the summary table.

Effect	Finding	With Mitigation	Mitigation Measure
CC-1: Increase in Greenhouse Gas Emissions during Construction	Less than significant	N/A	N/A
CC-2: Conflict with an Applicable Plan, Policy or Regulation Adopted for the Purpose of Reducing the Emissions of GHGs	Less than significant	N/A	N/A
CC-3: Changes in Flood Frequency and Floodwater Elevation Caused by Global Climate Change	Less than significant	N/A	N/A

Effect CC-1: Increase in Greenhouse Gas Emissions during Construction

Both SMAQMD and YSAQMD have not formally adopted GHG thresholds for projects such as the CHP Academy EIP. Therefore, a presumptive threshold of 7,000 metric tons (the lowest threshold of any formally adopted GHG threshold) is compared against the CO_2 emissions for the CHP Academy EIP. As noted in Table 4.8-3, the CO_2 emissions project-wide without mitigation would be 1,290 metric tons per year. Within YSAQMD and SMAQMD, respectively, CO_2

emissions without mitigation would be 1,115 and 174 metric tons per year. These emissions are well below the presumptive threshold and the effects of GHG emissions during construction are considered less than significant.

Effect CC-2: Conflict with an Applicable Plan, Policy or Regulation Adopted for the Purpose of Reducing the Emissions of Greenhouse Gases

The CHP Academy APA does not pose any apparent conflict with the goals of AB 32, the key elements and GHG reduction measures in the Climate Change Scoping Plan, or any other plans for reduction or mitigation of GHGs. To date, no federal, state, or local agency with jurisdiction over the proposed project has adopted plans or regulations that set specific goals for emission limits or emission reductions applicable to the proposed levee improvement project. As described in Effect CC-1, the average forecast emissions from the implementation of the proposed project were compared to conservatively low presumptive significance thresholds that were derived from the draft GHG guidelines published by several local air quality agencies. The forecast emission rates are well below the presumptive significant threshold. Therefore, the proposed project would not conflict with or obstruct the implementation of greenhouse gas emission reduction plans. This effect is less than significant.

Effect CC-3: Changes in Flood Frequency and Floodwater Elevation Caused by Global Climate Change

Global climate change could affect the hydrology of the Sacramento River, including the frequency of future flood events and the intensity of future flood events. As described in Section 3.2, Flood Control and Geomorphology, Projections of Future Mean Sea Level Change (p.3.2-51), the entire WSLIP program area (including the Sacramento Bypass) is relatively insensitive to the projected changes in sea level rise. This effect is less than significant.

4.8.5.3 CHP Academy Alternative B

Implementation of the CHP Academy Alternative B would result in the following effects on climate change. A description of these effects is provided below the summary table.

Effect	Finding	With Mitigation	Mitigation Measure
CC-1: Increase in Greenhouse Gas Emissions during Construction	Less than significant	N/A	N/A
CC-2: Conflict with an Applicable Plan, Policy or Regulation Adopted for the Purpose of Reducing the Emissions of GHGs	Less than significant	N/A	N/A
CC-3: Changes in Flood Frequency and Floodwater Elevation Caused by Global Climate Change	Less than significant	N/A	N/A

Effect CC-1: Increase in Greenhouse Gas Emissions during Construction

Both SMAQMD and YSAQMD have not formally adopted GHG thresholds for projects such as the CHP Academy EIP. Therefore, a presumptive threshold of 7,000 metric tons (the lowest threshold of any formally adopted GHG threshold) is compared against the CO_2 emissions for the CHP Academy EIP. As noted in Table 4.8-5, the CO_2 emissions project-wide without mitigation would be 577 metric tons per year. Within YSAQMD and SMAQMD, respectively, CO_2 emissions without mitigation would be 543 and 34 metric tons per year. These emissions are well below the presumptive threshold and the effects of GHG emissions during construction are considered less than significant.

Effect CC-2: Conflict with an Applicable Plan, Policy or Regulation Adopted for the Purpose of Reducing the Emissions of Greenhouse Gases

This effect is the same as described above under the CHP Academy APA. The effect is considered less than significant. No mitigation is required.

Effect CC-3: Changes in Flood Frequency and Floodwater Elevation Caused by Global Climate Change

This effect is the same as described above under the CHP Academy APA. The effect is considered less than significant. No mitigation is required.

Section 4.9
Noise—
CHP Academy Early Implementation Project

4.9.1 Affected Environment

This section describes the affected environment for noise in the CHP Academy EIP project area, including the regulatory and environmental settings.

4.9.1.1 Regulatory Setting

4.9.1.1.1 State

There are no state policies related to noise that would apply to the implementation of the CHP Academy EIP. However, the *General Plan Guidelines* published by the Governor's Office of Planning and Research (2003) include recommendations for maximum noise exposure based on type of land use. These recommendations are available for counties and cities to adopt as part of their state-mandated requirement in establishing policies and standards in their general plans regarding incompatibilities between land uses as they relate to noise exposure.

There are no applicable Federal, state, or local quantitatively-defined regulations relating to vibration resulting from construction activities. Thresholds for annoyance and structural damage reported by Caltrans (2004) are used in this analysis. Please see the program information in Section 3.7.2.2, Regulatory Setting, for a more complete description of these thresholds.

4.9.1.1.2 Local

The following local policies related to noise may apply to the implementation of the CHP Academy EIP. Please see the program information in Section 3.7.2.2, Regulatory Setting, for a more complete description of each policy.

- City of West Sacramento Noise Ordinance
- City of Sacramento Noise Ordinance
- *City of West Sacramento General Plan*
- *Yolo County General Plan*
- *City of Sacramento General Plan*

4.9.1.2 Environmental Setting

The environmental setting for the CHP Academy EIP is described in the Program Area Affected Environment. This section presents additional setting information specifically related to noise for the CHP Academy EIP project area.

Noise-sensitive land uses in the vicinity of the project area are primarily residential uses located across the Sacramento River in the City of Sacramento, with the closest residences located on

Garden Highway within 900 feet of the east terminus of the levee reach and 1,900 feet from the staging/mixing area. In addition, the CHP Academy, located south of the reach in the city of West Sacramento, would be considered noise-sensitive at buildings where cadets are housed (during nighttime hours) or trained (during daytime hours). The closest noise-sensitive CHP Academy dormitory building is located at a distance of approximately 1,500 feet south of the levee reach and 1,700 feet south of the staging/mixing area.

The primary existing noise sources in the vicinity of the proposed project are vehicular traffic on I-80 and local roadways. Secondary noise sources include boating traffic on the Sacramento River, agricultural and industrial operations, and airplane and helicopter flyovers (to and from the CHP Academy and regional airports and facilities).

I-80 is the dominant noise source in the area, and existing noise levels in the vicinity of the proposed project depend on relative distance from this freeway. Traffic noise levels in the vicinity of I-80 were calculated at various distances using the existing traffic volumes (California Department of Transportation 2007) and the Federal Highway Administration (FHWA) Traffic Noise Model (Version 2.5). Table 4.9-1 summarizes the results of modeling. Estimated peak-hour daytime traffic noise levels at the noise-sensitive receptors nearest the levee reach are 63 to 64 dBA. Nighttime noise levels near major freeways are typically 10 to 15 dBA quieter than the peak-hour daytime levels, so the estimated nighttime noise levels at the closest noise-sensitive receptors are likely 48 to 54 dBA.

Table 4.9-1. Modeled Peak Hour Traffic Noise Levels in the Vicinity of the CHP Academy Site

Distance from Interstate 80 (feet)	Noise-Sensitive Receptor	Peak Hour Daytime Traffic Noise L_{eq} (dBA)	Estimated Nighttime L_{eq} (dBA)
2,000	City of Sacramento homes closest to levee reach	64	49–54
2,200	CHP buildings closest to levee reach	63	48–53

4.9.2 Environmental Consequences

This section describes the environmental consequences relating to noise for the proposed CHP Academy EIP. It describes the methods used to determine the effects of the project and lists the thresholds used to conclude whether an effect would be significant. The effects that would result from implementation of CHP Academy EIP project, findings with or without mitigation, and applicable mitigation measures are presented in a summary table. These effects tier from the program analysis effects described in Section 3.7.3.3, Effects and Mitigation Measures.

4.9.2.1 Assessment Methods

This analysis focuses on the potential construction-related and operational noise effects associated with the CHP Academy EIP project. Methods recommended by the Federal Transit Administration have been used to assess construction noise. Potential noise effects associated with construction activities have been evaluated by assuming the simultaneous operation of multiple pieces of heavy equipment as a reasonable upper bound for noise effects.

Temporary groundborne vibration from construction activity has also been assessed using methods recommended by the Federal Transit Administration (2006).

4.9.2.2 Determination of Effects

Determination of effects for noise and vibration for the CHP Academy EIP is the same as under the Program Area Environmental Consequences.

It is possible that construction activity for levee improvements might have to be conducted at night to respond to expedited schedule requirements. Therefore, the noise analyses described in this section assumes the project must comply with nighttime noise ordinance limits for the two local jurisdictions:

- CHP Academy dormitories within the city of West Sacramento: 45 dBA (L_{eq}); 65 dBA (L_{max})
- City of Sacramento dwellings: 54 dBA (L_{eq}); 70 dBA (L_{max})

The CHP Academy EIP would require the use of heavy construction equipment. Table 4.9-2 summarizes typical construction noise emission levels for the types of equipment proposed for use.

Table 4.9-2. Typical Construction Equipment Noise Emission Levels

Equipment	Typical Noise Level (L_{max})[1]	Equipment	Typical Noise Level (L_{max})[1]
Backhoe	78	Grader	85
Batch mixing plant	83	Haul truck[2]	76
Compactor	83	Maintainer[5]	77
Dozer	82	Paver	77
Dump truck	76	Pickup truck	75
Excavator	81	Roller	80
Forklift[3]	75	Scraper	84
Front-end loader	79	Trackhoe[4]	78
Water truck[2]	76	Water truck[2]	76

Source: Federal Highway Administration 2006.
[1] dBA, A-weighted decibel level, measured at 50 feet.
[2] Based on data for dump truck.
[3] Based on data for pickup truck.
[4] Based on data for backhoe.
[5] Based on data for paver.

4.9.2.2.1 Effect Assumptions

The following assumption regarding project effects on noise in the CHP Academy area has been made for this analysis:

- Vibration from non-impact/impulsive construction equipment typically attenuates below significant levels within about 50 feet of construction activity, and is not anticipated to result in a significant effect during implementation of the project. Therefore, effects from non-impulsive construction equipment are not discussed further in this section.

4.9.3 Effects and Mitigation Measures

4.9.3.1 No Action Alternative

The No Action Alternative represents the continuation of the existing deficiencies along the portion of the Sacramento Bypass Levee reach in the CHP Academy EIP project area. Current levee operations and maintenance activities would continue, but there would be no noise or vibration associated with new construction or operational activities.

Because no levee improvements would be made under the No Action Alternative, the risk that the Sacramento Bypass Levee could fail due to seepage or slope stability or geometry issues would continue. Failure of the Sacramento Bypass Levee, depending on the magnitude of the event, could cause catastrophic flooding of the magnitude described in the Noise program analysis (Section 3.7.3.3.1). In summary, those effects could include excessive noise and vibration levels for extended periods of time due to flood-fighting and cleanup efforts. However, the timing, duration and magnitude of a flood event are speculative and unpredictable, and therefore a precise determination of significance is not possible.

4.9.3.2 CHP Academy Applicant Preferred Alternative

Implementation of the CHP Academy APA would result in the following noise-related effects. A description of these effects is provided below the summary table.

Effect	Finding	With Mitigation	Mitigation Measure
NZ-1: Exposure of Sensitive Receptors to Temporary Construction-Related Noise	Less than significant	N/A	N/A
NZ-3: Exposure of Sensitive Receptors to Intermittent Noise as a Result of Ongoing Maintenance Activities and Permanent Facility Operations	Less than significant	N/A	N/A

Effect NZ-1: Exposure of Sensitive Receptors to Temporary Construction-Related Noise

Under the CHP Academy APA, levee deficiency improvements would be constructed along a 6,500-foot-long area of the Sacramento Bypass Levee reach. The CHP Academy APA would include two sequential stages of construction activity: construction of slurry cutoff walls using the conventional slot trench method, and waterside slope flattening. As described in the program analysis, noise levels generated during slope flattening activity would be lower than those generated during slurry wall construction. Therefore, the following noise impact assessment focuses on the louder activity (combined slurry wall and staging/mixing area).

Construction equipment proposed for slurry wall construction would include long-reach trackhoes, dump trucks, haul trucks, loaders, rough-terrain forklifts, compactors, maintainers, and water trucks.

The three loudest pieces of equipment employed during slurry cutoff wall construction would likely be the compactor, dozer and long-reach excavator. The loudest pieces of equipment at the

staging/mixing area would include a loader, a batch mixing plant, and a haul truck. The total noise emissions from the combined slurry wall and staging/mixing area activity would be 89 dBA (L_{max}) at 50 feet and 83 dBA (L_{eq}) at 50 feet.

Table 4.9-3 summarizes noise levels at various distances projected from the simultaneous construction activity for the slurry wall and staging/mixing area. That table compares the modeled L_{max} and L_{eq} noise levels to the nighttime noise ordinance limits at each of the noise sensitive receptors.

Construction equipment proposed for slope flattening includes motor graders, sheepsfoot rollers, haul trucks and water trucks. The three loudest pieces of equipment under this treatment option would be the grader, roller, and large truck (haul or water). The total noise emissions from the slope-flattening construction activity would be 87 dBA (L_{max}) at 50 feet and 82 dBA (L_{eq}) at 50 feet.

Table 4.9-3. Projected Construction Noise Levels due to Slurry Cutoff Wall Installation (Including Staging/Mixing Area)

Distance between Source and Receiver (feet)	Noise Receptor	Calculated L_{max} Sound Level (dBA)	Calculated L_{eq} Sound Level (dBA)	L_{max} Nighttime Noise Limit (dBA)	L_{eq} Nighttime Noise Limit (dBA)
900	Homes along Garden Highway in City of Sacramento	54	50	701	54[1]
1,600	Closest dormitories at CHP Academy	47	43	65[2]	45[2]

Calculations based on Federal Transit Administration 2006.

[1] Nighttime noise ordinance limit for City of Sacramento.

[2] Nighttime noise ordinance limit for City of West Sacramento.

Note: This calculation does not include the effects, if any, of local shielding from walls, topography or other barriers.

The closest dormitories at the CHP Academy and the closest homes across the river in the city of Sacramento are relatively far from the construction areas, so the modeled noise levels at those receptors would be lower than the respective nighttime noise ordinance limits. Therefore, construction noise effects would not be significant, even if nighttime construction is required.

Similarly, construction-related haul trucks and commute vehicles traveling along public streets are not expected to cause 24-hour day-night (L_{dn}) noise levels exceeding the City's noise limits for transportation noise sources. The highest truck traffic volumes along residential streets would occur along North Harbor Boulevard, where there are single-family and multi-family dwellings along the road. As described in Section 4.7, Transportation and Navigation, temporary construction activity could generate up to 298 haul truck trips per day and 58 worker commute trips per day. If the haul trucks and commute vehicles were used 24 hours per day, project-related traffic noise levels at the existing dwellings along North Harbor Boulevard would be 61 dBA-L_{dn}. That project-related L_{dn} noise level is less than the 65 dBA-L_{dn} limit set by the City's noise ordinance. If haul trucks usage could be restricted to daytime hours, then the resulting L_{dn} noise levels would be lower. Therefore, this impact would be less than significant. No mitigation is required.

Effect NZ-3: Exposure of Sensitive Receptors to Intermittent Noise Due to Ongoing Maintenance Activities and Permanent Facility Operations

There would be no additional ongoing flood control related levee maintenance activities at areas subsequently treated with cutoff wall installations beyond current maintenance activities. Areas treated with slope flattening would be regularly mowed and maintained to control vegetation. Recreation trail maintenance would include sweeping, pavement repair, removal of obstacles, and periodic asphalt overlays. These maintenance activities would not have a significant effect on noise or vibration. Therefore, this effect would be considered less than significant. No mitigation is required.

4.9.3.3 CHP Academy Alternative B

Implementation of the CHP Academy APA would result in the following noise-related effects. A description of these effects is provided below the summary table.

Effect	Finding	With Mitigation	Mitigation Measure
NZ-1: Exposure of Sensitive Receptors to Temporary Construction-Related Noise	Less than significant	N/A	N/A
NZ-3: Exposure of Sensitive Receptors to Intermittent Noise as a Result of Ongoing Maintenance Activities and Permanent Facility Operations	Less than significant	N/A	N/A

Effect NZ-1: Exposure of Sensitive Receptors to Temporary Construction-Related Noise

Under CHP Academy Alternative B, levee treatments and construction practices along the Sacramento Bypass reach would consist of two sequential stages of construction activity:

- Stability berm construction using a grader, dozer, and compactor. As described in the program noise analysis, the combined noise emissions from the loudest equipment would be 88 dBA (L_{max}) and 84 dBA (L_{eq}).
- Relief well installation using a drill rig, an excavator, and a water truck. As described in the program noise analysis, the combined noise emissions from the loudest equipment would be 84 dBA (L_{max}) and 81 dBA (L_{eq}).

Construction of the stability berm would generate the loudest noise levels. Therefore, the noise impact assessment focuses on that stage of construction. This assessment assumes that nighttime construction might be required.

Noise sensitive receptors are the same as those considered for the CHP Academy APA: the closest dormitories at the CHP Academy within the City of West Sacramento (1,600 feet from the levee reach); and homes along Garden Highway in the City of Sacramento (900 feet from the eastern terminus of the levee reach). As described previously each of those jurisdictions has its own nighttime noise ordinance limits.

Noise generated by nighttime construction of the stability berm (the loudest activity forecast for Alternative B) was modeled. Table 4.9-4 lists the forecast construction noise levels at each noise sensitive receptor, and compares the forecast values to the respective nighttime noise ordinance limits.

Table 4.9-4. Projected Construction Noise Levels during Alternative B Stability Berm Construction

Distance between Source and Receiver (feet)	Noise Receptor	Calculated L_{max} Sound Level (dBA)	Calculated L_{eq} Sound Level (dBA)	L_{max} Nighttime Noise Limit (dBA)	L_{eq} Nighttime Noise Limit (dBA)
900	Homes along Garden Highway in City of Sacramento	55	51	70[1]	54[1]
1,600	Closest dormitories at CHP campus	48	44	65[2]	45[2]

Calculations based on Federal Transit Administration 2006.
[1] Nighttime noise ordinance limit for City of Sacramento.
[2] Nighttime noise ordinance limit for City of West Sacramento.
This calculation does not include the effects, if any, of local shielding from walls, topography or other barriers.

Forecast nighttime noise levels generated by the loudest construction activity are less than the nighttime noise ordinance limits. Therefore, noise impacts would be less than significant even if nighttime construction is required.

Similar to the CHP APA, haul trucks and worker commute vehicles traveling along public streets would not cause project-related traffic noise to exceed the City's noise ordinance limits, even if haul trucks were used 24 hours per day. Forecast traffic noise levels for the APA are less than the City's noise ordinance limit, and Alternative B would generate lower traffic volumes than the APA. Therefore, traffic noise generated by Alternative B would also be less than the City noise ordinance limited. This effect would be less than significant. No mitigation is required.

Effect NZ-3: Exposure of Sensitive Receptors to Intermittent Noise Due to Ongoing Maintenance Activities and Permanent Facility Operations

There would be no additional ongoing flood control related levee maintenance activities beyond what is currently undertaken to control vegetation and maintain the existing drainage ditch. Relief well maintenance would include annual inspection and test pumping every 2 years. Recreation trail maintenance would include sweeping, pavement repair, removal of obstacles, and periodic asphalt overlays. These maintenance activities would not have a significant effect on noise or vibration. Therefore, this effect would be considered less than significant. No mitigation is required.

Section 4.10

Vegetation and Wetlands—CHP Academy Early Implementation Project

4.10.1 Affected Environment

This section describes the affected environment for vegetation and wetlands in the CHP Academy EIP project area, including regulatory and environmental setting.

4.10.1.1 Regulatory Setting

4.10.1.1.1 Federal

The following Federal policies related to vegetation and wetlands may apply to implementation of the CHP Academy EIP. Please see Section 3.8.2.1, Regulatory Setting, for a more complete description of each policy.

- Endangered Species Act
- Clean Water Act
- Rivers and Harbors Act
- Executive Order 11990: Protection of Wetlands
- Executive Order 13112: Invasive Species

4.10.1.1.2 State

The following state policies related to vegetation and wetlands may apply to implementation of the CHP Academy EIP. Please see Section 3.8.2.1, Regulatory Setting, for a more complete description of each policy.

- California Endangered Species Act
- California Native Plant Protection Act
- California Fish and Game Code
- Porter-Cologne Water Quality Control Act

4.10.1.1.3 Local

The following local policies related to vegetation and wetlands may apply to implementation of the CHP Academy EIP. Please see Section 3.8.2.1, Regulatory Setting, for a more complete description of each policy.

- *Yolo County General Plan*
- *Yolo County Oak Woodland Conservation and Enhancement Plan*
- *City of West Sacramento General Plan*
- *City of West Sacramento Tree Preservation Ordinance*

4.10.1.2 Environmental Setting

This section discusses the environmental setting related to vegetation and wetlands in the CHP Academy EIP project area.

4.10.1.2.1 Study Area

For the purposes of this section, the CHP Academy EIP study area consists of the project disturbance footprint plus an additional 100-foot-wide buffer zone to support an assessment of potential indirect effects. The width of the buffer zone was selected to account for indirect effects on elderberry shrubs (*Sambucus mexicana*) that are the host plant for the federally threatened valley elderberry longhorn beetle (VELB), which is discussed in Section 3.10, Wildlife. The study area occurs within the Great Central Valley subdivision of the California Floristic Province in Yolo County (Hickman 1993: 44, 45) and encompasses a portion of the Sacramento Bypass Levee near the CHP Academy. The majority of the study area consists of the levee itself. The levee crown and the eastern portion of the levee slope adjacent to the bypass are paved. The levee slope facing the CHP Academy and the western portion of the levee slope adjacent to the bypass support ruderal annual grassland. Additionally, an unpaved road is located approximately halfway down the levee slope adjacent to the CHP Academy. The topography of the portions of the study area adjacent to the levees is relatively level and elevations in the study area range from approximately 15 to 36 feet above mean sea level.

4.10.1.2.2 Field Surveys

The methods used to identify vegetation and wetland resources in the study area consisted of a pre-field investigation, reconnaissance-level site visits, a delineation of wetlands and waters, an arborist survey, and a botanical survey. Each of these components is described below.

Pre-Field Investigation

Prior to conducting the reconnaissance-level site visits, an ICF International botanist/wetland ecologist reviewed information pertaining to vegetation and wetland resources in the project region from the sources listed below.

- a CNDDB records search of the USGS 7.5-minute Sacramento West, Sacramento East, Grays Bend, Taylor Monument, Rio Linda, Davis, Clarksburg, Saxon, and Florin quadrangles (California Natural Diversity Database 2009a);
- the USFWS list of endangered, threatened, and proposed species for the U.S. Geological Survey 7.5-minute Sacramento West quadrangle and Yolo County obtained from the USFWS web site (U.S. Fish and Wildlife Service 2009a); and
- the CNPS 2007 online *Inventory of Rare and Endangered Plants of California* (California Native Plant Society 2009a).

No Federal, state, or local regulatory agencies were contacted prior to conducting the pre-field investigation; however, it was not appropriate at that time because the potential for the study area to contain sensitive vegetation and wetland resources could not be completely evaluated without field observations.

Reconnaissance-Level Site Visits

The botanist/wetland ecologist conducted three reconnaissance-level site visits to evaluate existing vegetation and wetland resources in the study area. The field visits were conducted on September 19 and October 5, 2007, and January 9 and February 13, 2009. The purpose of the site visits was to:

- Identify land cover types and compare field observations with existing vegetation data.
- Evaluate whether potential habitat may be present for special-status plant species that have been identified in the project region.
- Identify potential wetlands and other waters of the United States and/or state that these should be delineated during future surveys (see discussion below).
- Identify trees that may potentially be protected under the City of West Sacramento's Tree Preservation Ordinance.
- Identify invasive plant species present in the study area.

Delineation of Wetlands and Other Waters

An ICF International soil scientist and a botanist delineated wetlands and other waters of the United States in the study area on December 29, 2008, and March 20 and August 13, 2009. The delineation was conducted to identify the types and locations of wetlands and other waters that may be subject to regulation by Federal (USACE) and/or state (Central Valley RWQCB) agencies. The delineation was conducted in accordance with guidance provided in the 1987 *U.S. Army Corps of Engineers Wetlands Delineation Manual* (Environmental Laboratory 1987: 53–69), the *Regional Supplement to the Corps of Engineers 1987 Manual: Arid West Region* (U.S. Army Corps of Engineers 2008), and USACE Regulatory Guidance Letter RGL 05-05 (U.S. Army Corps of Engineers 2005). The delineation was conducted to support the submission of a preliminary jurisdictional determination to the USACE Sacramento District and to obtain wastewater discharge requirements from the Central Valley RWQCB for waters of the state.

Arborist Survey

An ICF International arborist conducted tree surveys on December 16 and 17, 2008. The arborist survey methods follow standard professional practices and all tree location data were collected with a global positioning system unit with sub-meter accuracy. The arborist recorded the species, number of trunks, and diameter at breast height (diameter at 4.5 feet above the ground surface, unless otherwise noted, measured with a calibrated diameter-at-breast-height tape), tree height, dripline diameter, and the health and vigor of each tree. At the time of the arborist survey, the boundary of the study area was located approximately 400 feet west of the depressional wetland, so the trees located west of that previous boundary were not surveyed. Arborist surveys of these areas will be completed prior to project implementation.

Botanical Survey

Two ICF International botanists conducted a botanical survey in the study area on April 30, 2009. The botanists walked meandering transects throughout the study area. All plant species observed were identified to the level necessary to determine if they were special-status plants or were plant species with unusual or significant range extensions. The list of all plants observed in the study area is included as Appendix F.

4.10.1.2.3 Land Cover Types

The study area contains the following land cover types: Great Valley mixed riparian forest, non-native annual grassland, depressional wetland, drainage ditch, open water, and levee/developed/landscaped. The Great Valley mixed riparian forest and non-native annual grassland are natural communities identified in DFG's List of California Terrestrial Natural Communities Recognized by the California Natural Diversity Database (California Department of Fish and Game 2003). The depressional wetland was classified using the hydrogeomorphic approach described by Brinson (1993: 7–9). Each of the land cover types is discussed below and shown in Figure 4.10-1.

Great Valley Mixed Riparian Forest

Great Valley mixed riparian forest surrounds the depressional wetland and pond within the Sacramento Bypass (Figure 4.10-1). The study area contains a total of 1.16 acres of Great Valley mixed riparian forest and only 0.03 acre occurs within the project disturbance footprint. The dominant overstory species are Fremont cottonwood (*Populus fremontii* ssp. *fremontii*), Goodding's black willow (*Salix gooddingii*), and valley oak (*Quercus lobata*). The shrub layer is relatively open and contains small valley oaks, box elder (*Acer negundo* var. *californicum*), and tree tobacco (*Nicotiana glauca*). Representative species observed in the herbaceous understory were mugwort (*Artemisia douglasiana*), rough cocklebur (*Xanthium strumarium*), and cudweed (*Gnaphalium luteo-album*). None of the trees observed in the Great Valley mixed riparian forest met the definition of heritage or landmark trees as defined in the City's Tree Preservation Ordinance. Riparian forest is identified as a sensitive natural community by the CNDDB (California Natural Diversity Database 2009b).

Riparian communities in general are some of the richest community types in terms of structural and biotic diversity of any plant community found in California. Riparian vegetation provides three important functions in addition to that of wildlife habitat: 1) acts as a travel lane between the river and adjacent uplands, providing an important migratory corridor for wildlife; 2) filters out pollutants, thus protecting water quality; and 3) helps to reduce the severity of floods by stabilizing riverbanks.

Despite widespread disturbances resulting from urbanization, agricultural conversion, and grazing, riparian forests remain important wildlife resources because of their scarcity regionally and statewide and because riparian communities are used by a large variety of wildlife species.

Non-Native Annual Grassland

The majority of the non-native annual grassland in the CHP Academy EIP study area occurs within the Sacramento Bypass (Figure 4.10-1). A total of approximately 19.03 acres of non-native annual grassland occur within the study area and approximately 8.29 acres are located within the project disturbance footprint. Rattail fescue (*Vulpia myuros* var. *myuros*) and soft chess (*Bromus hordeaceus*) were the dominant species observed in the non-native annual grassland in the Sacramento Bypass basin, and the dominant forbs observed were perennial pepperweed (*Lepidium latifolium*), winter vetch (*Vicia villosa* ssp. *varia*), and mugwort. Other species observed in the grassland were red brome (*Bromus madritensis* ssp. *rubens*), yellow star-thistle (*Centaurea solstitialis*), foxtail barley (*Hordeum murinum* spp. *leporinum*), perennial pepperweed (*Lepidium latifolium*), and Italian ryegrass (*Lolium multiflorum*). The non-native annual grassland within the Sacramento Bypass basin

contained a high proportion of forb species. A large elderberry shrub (*Sambucus mexicana*) was observed in the non-native annual grassland within the bypass. Narrow swaths of non-native annual grassland that occur on the levee itself were included in the levee/developed/landscaped land cover type described below. In general, the annual grasslands in the study area contain a relatively large proportion of ruderal species, likely as a result of the substantial degree of disturbance from human activities.

Depressional Wetland

A single depressional wetland encompassing 2.91 acres was delineated in the study area (Figure 4.10-1). The depressional wetland is located entirely within the buffer zone component of the study area (i.e., outside the project disturbance footprint). The depressional wetland is located within the Sacramento Bypass basin and appears to receive most of its hydrologic input from groundwater in addition to direct precipitation and surface runoff. The depressional wetland is shaded by the Great Valley mixed riparian forest and does not support emergent marsh vegetation (i.e. cattails [*Typha* sp.] and tules [*Scirpus* sp.]). The depressional wetland was inundated at the time of the delineation of wetlands and waters and at the time of the botanical survey.

The depressional wetland does not provide habitat for the special-status plants known from the project region that occur in vernal pools or marshes because it does not support vernal pool or marsh vegetation and lacks the restrictive hardpan layer that characterizes vernal pools.

Dominant plant species associated with the depressional wetland were weedy species: knotweed (*Polygonum* sp.), Bermuda grass, perennial peppergrass, and rough cocklebur. The depressional wetland is surrounded by Great Valley mixed riparian forest and would be considered a sensitive natural community even though it is not listed on DFG's *List of California Terrestrial Natural Communities Recognized by the California Natural Diversity Database* (California Department of Fish and Game 2003) because state and Federal regulatory agencies consider wetlands sensitive habitats.

Drainage Ditch

The study area contains several segments of a drainage ditch that that occurs parallel to the south side of the Sacramento Bypass levee. The drainage ditch appears to be ephemeral and no water was observed during the site visits. The area of the drainage encompassed by the study area is 0.13 acre and the drainage ditch is located entirely in the buffer zone of the study area. The drainage ditch appears to drain upland areas between the CHP Academy and the Sacramento Bypass levee.

Open Water

For the purposes of this analysis, the open water category includes the small pond at the western edge of the study area within the Sacramento Bypass and the canal, which are both located within the buffer zone of the study area. Within the study area, the pond encompasses 0.19 acre and the canal encompasses 0.12 acre. The pond is bordered by Great Valley mixed riparian forest to the north, east, and south and by freshwater marsh to the west. A pipe (approximately 3 feet in diameter) was observed above the water level on the south side of the pond and appears to periodically convey water pumped from the canal into the pond. The unnamed canal is bordered by the CHP Academy on the east and on the west by the levee. A pumping station is located at the north end of the canal. Although small clumps of tules and cattail were observed along the canal edges in the section located in the study area, the channel is essentially unvegetated.

Levee/Developed/Landscaped

The levee/developed/landscaped land cover type is comprised of the levee itself as well as areas that are developed and/or landscaped (Figure 4.10-1). This land cover type that encompasses approximately 38.692 acres also includes unpaved roads and trails and areas that appear to have been mowed. The levee crown and the eastern portion of the levee slope adjacent to the bypass are paved, and an unpaved road is located approximately halfway down the levee slope adjacent to the CHP Academy. The levee slope facing the CHP Academy and the western portion of the levee slope adjacent to the bypass both support narrow swaths of non-native annual grassland dominated by slender wild oat (*Avena barbata*), ripgut brome (*Bromus diandrus*), and soft chess. The non-native grassland on the levee slope facing the CHP Academy appears to be periodically mowed as part of routine levee maintenance. The trees observed in the southeastern portion of the study area consist of a mixture of native oak trees (*Quercus* spp.) and species planted for landscaping purposes, e.g., coast redwood (*Sequoia sempervirens*), catalpa (*Catalpa* sp.), and London planetree (*Platanus hybrida*). Several elderberry shrubs were observed between the railroad tracks and Old River Road in the southeastern portion of the study area.

4.10.1.2.4 Waters of the United States, Including Wetlands

The study area contains 3.35 acres of potential waters of the United States consisting of the depressional wetland (2.91 acres), drainage ditch (0.13 acre), pond (0.19 acre), and canal (0.12 acre). Although portions of the Sacramento Bypass basin are inundated (e.g., depressional wetland, pond) and meet the three USACE wetland criteria (i.e., hydrophytic vegetation, hydric soils, & wetland hydrology), areas sampled in the remainder of the portion of the basin located within the study area do not meet all three wetland criteria. In accordance with USACE guidelines for submitting a preliminary jurisdictional determination, these features were interpreted to be subject to USACE regulation under Section 404 of the CWA. This determination is preliminary and subject to verification by the Sacramento District of the USACE as part of the review process. The depressional wetland and the drainage ditch also qualify as waters of the state. The detailed wetland delineation report is being submitted to the USACE as part of the CWA Section 404 permitting process.

4.10.1.2.5 Special-Status Plant Species

Special-status plant species are plants that are legally protected under CESA, ESA, or other regulations, as well as species considered sufficiently rare by the scientific community to qualify for such listing. Categories of special-status plant species are described above in Program Affected Environment.

No special-status plant species occur in the study area based on one or more of the following findings: absence of habitat, absence of suitable microhabitat, and lack of occurrence during site visits. Eighteen of the 34 special-status plant species identified above in the Program Affected Environment were identified as occurring in the project region (California Natural Diversity Database 2009b; California Native Plant Society 2009b; U.S. Fish and Wildlife Service 2009b). The number of special-status plant species identified as having the potential to occur in the program study area differs from the number of special-status plants identified as potentially occurring in the project study area because the project study area encompasses a much smaller area. Four of the eighteen species are federally and/or state-listed as endangered or threatened: palmate-bracted bird's-beak (*Cordylanthus palmatus*), Boggs Lake hedge hyssop (*Gratiola heterosepala*), Colusa grass (*Neostapfia colusana*), and Crampton's tuctoria (*Tuctoria mucronata*). The status, distribution,

habitat requirements, and identification period of the eighteen species are shown in Table 4.10-1. One of the species, little mousetail (*Myosurus minimus* ssp. *apus*), occurs at elevations that are at least 30 feet higher than the highest elevation within the study area. Although the Great Valley mixed riparian forest is potential habitat for northern California black walnut, no protected native stands were observed during any of the site visits.

Five of the remaining sixteen species occur in habitats (i.e., vernal pools, marshes) that are not present in the study area: Bogg's Lake hedge hyssop (*Gratiola heterosepala*), rose-mallow (*Hibiscus lasiocarpus*), legenere (*Legenere limosa*), Colusa grass (*Neostapfia colusana*), and Sanford's arrowhead (*Sagittaria sanfordii*). Although habitat is present in the grassland for eight of the remaining ten species, suitable microhabitat (mesic areas, adobe clay soils, alkaline soils) is not present. No mesic areas were observed during site visits and no alkaline, serpentine, or adobe clay soils have been documented in the three soil mapping units present in the study area: Lang sandy loam, deep; Lang sandy loam, deep, flooded; and Sycamore silt loam (Andrews 1972; 15, 16, 33, 34). Two special-status plant species, stinkbells (*Fritillaria agrestis*) and heartscale (*Atriplex cordulata*) were determined to have low potential to occur in the study area. No special-status plants were observed in the study area during the April 30, 2009 botanical survey that coincided with the identification periods of stinkbells and heartscale (California Native Plant Society 2009b).

The timing of the survey also coincided with the identification period of eight other special-status plant species identified during the pre-field investigation as occurring in the project region (California Native Plant Society 2009b) but for which the project study area lacked suitable habitat or microhabitat. Therefore, the proposed CHP Academy alternatives would not have a significant effect on special-status plants and effects on special-status plants are not discussed further. The closest special-status plant occurrence to the study area is rose-mallow that has been documented approximately 1 mile northeast of the Sacramento River North Levee (California Natural Diversity Database 2009b); however, no suitable habitat (i.e., freshwater marsh) is present in the CHP Academy study area.

Table 4.10-1. Special-Status Plants Identified as Occurring in the Project Region for the CHP Academy EIP

Common and Scientific Name	Legal Status[a] Federal/ State/CNPS	Geographic Distribution/Floristic Province[1]	Habitat Requirements	Identification Period	Potential for Occurrence in CHP Academy Study Area
Ferris's milk vetch *Astragalus tener* var. *ferrisiae*	–/–/1B.1	Historic range included the Central Valley from Butte to Alameda Counties; currently only occurs in Butte and Glenn Counties	Seasonally wet areas in meadows and seeps, sub-alkaline flats in valley and foothill grassland; 16–246 feet	Apr–May	Habitat present in grasslands but no suitable microhabitat (i.e., alkaline flats) is present. No occurrences within 10 mi.
Alkali milk vetch *Astragalus tener* var. *tener*	–/–/1B.2	Southern Sacramento Valley, northern San Joaquin Valley, eastern San Francisco Bay	Playas, on adobe clay in valley and foothill grassland, vernal pools on alkali soils; below 197 feet	Mar–Jun	Habitat present in grasslands but suitable microhabitat (i.e., adobe clay) is not present. Nearest occurrence is ~9 mi. away.
Heartscale *Atriplex cordulata*	–/–/1B.2	Western Central Valley and valleys of adjacent foothills	Saline or alkaline soils in chenopod scrub, meadows and seeps, sandy areas in valley and foothill grassland; below 1,230 feet	Apr–Oct	Habitat present in grasslands and sandy soils occur in the study area, but grasslands are highly disturbed by human activities. No saline or alkaline soils have been documented in the study area. Nearest reported occurrence (extirpated) was ~7.5 mi away.
Brittlescale *Atriplex depressa*	–/–/1B.2	Western and eastern Central Valley and adjacent foothills on west side of Central Valley	Alkaline or clay soils in chenopod scrub, meadows and seeps, playas, valley and foothill grassland, vernal pools; below 1,050 feet	Apr–Oct	Habitat present in grasslands but no suitable microhabitat (i.e., alkaline soils) is present. Nearest occurrence is ~10 mi. away.
San Joaquin saltscale *Atriplex joaquiniana*	–/–/1B.2	Western edge of the Central Valley from Glenn to Tulare Counties	Alkaline soils in chenopod scrub, meadows and seeps, playas, valley and foothill grassland; below 2,739 feet	Apr–Oct	Habitat present in grasslands but no suitable microhabitat (i.e. alkaline soils) is present. Nearest occurrence is ~8 mi. away.

[1] Floristic provinces as defined in Hickman 1993.

Common and Scientific Name	Legal Status[a] Federal/ State/CNPS	Geographic Distribution/Floristic Province[1]	Habitat Requirements	Identification Period	Potential for Occurrence in CHP Academy Study Area
Palmate-bracted bird's-beak *Cordylanthus palmatus*	E/E/1B.1	Livermore Valley and scattered locations in the Central Valley from Colusa to Fresno Counties	Alkaline grassland, alkali meadow, chenopod scrub; 16–508 meters	May–Oct	Habitat present in grasslands but no suitable microhabitat (i.e., alkaline soils) is present. Nearest occurrence is ~8 mi. away.
Dwarf downingia *Downingia pusilla*	–/–/2.2	Inner North Coast Ranges, southern Sacramento Valley, northern and central San Joaquin Valley	Mesic areas in valley and foothill grassland, vernal pools; below 1,460 feet	Mar–May	Habitat present in grasslands but no suitable microhabitat (i.e., mesic areas) is present. Nearest occurrence is ~7.5 mi. away.
Stinkbells *Fritillaria agrestis*	–/–/4.2	Outer North Coast Ranges, Sierra Nevada foothills, Central Valley, Central Western California	Clay, sometimes serpentine soils in chaparral, cismontane woodland, pinyon-juniper woodland, valley and foothill grassland; 33–5,102 feet	March–June	Habitat present in grassland and clay subsoils may be present at surface from disturbance to study area. Overlap between highest study area elevation (36ft) and elevation range of species (i.e., 36–5,102 feet above mean sea level) is very minimal. Grasslands are highly disturbed from human activities. No serpentine soils occur in the study area. Nearest occurrence is ~8.5 mi. away.
Boggs Lake hedge hyssop *Gratiola heterosepala*	–/E/1B.2	Inner North Coast Ranges, central Sierra Nevada foothills, Sacramento Valley, Modoc Plateau	Marshes and swamps along lake margins, vernal pools on clay soils; 32–7,792 feet	Apr–Aug	No marsh or vernal pool habitat present. Nearest occurrence is ~10 mi. away.
Rose-mallow *Hibiscus lasiocarpos*	–/–/2.2	Central and southern Sacramento Valley, deltaic Central Valley, and elsewhere in the U.S.	Freshwater marsh along rivers and sloughs; below 394 feet	Jun–Sep	No marsh habitat present. Nearest occurrence is ~1 mi. away.

Common and Scientific Name	Legal Status[a] Federal/ State/CNPS	Geographic Distribution/Floristic Province[1]	Habitat Requirements	Identification Period	Potential for Occurrence in CHP Academy Study Area
Northern California black walnut *Juglans hindsii*	–/–/1B.1	Last two native stands in Napa and Contra Costa Counties; historically widespread through southern Inner North Coast Ranges, southern Sacramento Valley, northern San Joaquin Valley, San Francisco Bay	Riparian scrub and riparian woodland; below 1,443 feet	Apr–May	Riparian habitat present but no native stands observed during 2007 & 2009 field surveys. Nearest occurrences is ~9 mi. away.
Legenere *Legenere limosa*	–/–/1B.1	Sacramento Valley, North Coast Ranges, northern San Joaquin Valley and Santa Cruz mountains	Vernal pools; below 2,887 feet	Apr–Jun	No vernal pool habitat present. Nearest occurrence is ~7.5–8.5 mi. away.
Heckard's pepper-grass *Lepidium latipes* var. *heckardii*	–/–/1B.2	Southern Sacramento Valley	Alkaline flats in valley and foothill grassland; 32–656 feet	Mar–May	Habitat present in grasslands but no suitable microhabitat (i.e., alkaline soils) is present. Nearest occurrence is ~7 mi. away.
Little mousetail *Myosurus minimus* ssp. *apus*	–/–/3.1	Central Valley, San Francisco Bay area, southern Outer Coast Ranges, South Coast	Alkaline soils in valley and foothill grassland and vernal pools; 66–2,100 feet	Mar–Jun	Study area is substantially lower than species elevation range. No alkaline soils or vernal pool habitat present. No occurrences within 10 mi.
Baker's navarretia *Navarretia leucocephala* ssp. *bakeri*	–/–/1B.1	Inner North Coast Ranges, western Sacramento Valley	Mesic areas in cismontane woodland, lower montane coniferous forest, meadows and seeps, valley and foothill grassland, vernal pools;16–5,709 feet	Apr–Jul	Habitat present in grasslands but no suitable microhabitat (i.e., mesic areas) is present. No occurrences within 10 mi.
Colusa grass *Neostapfia colusana*	T/E/1B.1	Central Valley with scattered occurrences from Colusa to Merced Counties	Adobe soils of vernal pools; 16–656 feet	May–Aug	No vernal pool habitat present. Nearest occurrence is ~9 mi. away.
Sanford's arrowhead *Sagittaria sanfordii*	–/–/1B.2	Scattered locations in Central Valley and Coast Ranges from Del North to Fresno Counties	Freshwater marshes, sloughs, canals, and other slow-moving water habitats; below 2,132 feet	May–Oct	No marshes, sloughs, or canals present. Nearest occurrence is ~4.5 mi. away.

Common and Scientific Name	Legal Status[a] Federal/ State/CNPS	Geographic Distribution/Floristic Province[1]	Habitat Requirements	Identification Period	Potential for Occurrence in CHP Academy Study Area
Crampton's tuctoria *Tuctoria mucronata*	E/E/1B.1	Southwestern Sacramento Valley, Solano and Yolo Counties	Mesic areas in valley and foothill grassland, vernal pools; 16–33 feet	Apr–Aug	Habitat present in grasslands but no suitable microhabitat (i.e., mesic areas) is present. No vernal pool habitat present. Nearest occurrence is ~9 mi. away.

[a] Status explanations:

Federal

E = listed as endangered under the Federal Endangered Species Act.
T = listed as threatened under the Federal Endangered Species Act.
– = no listing.

State

E = listed as endangered under the California Endangered Species Act.
R = listed as rare under the California Native Plant Protection Act (this category is no longer used for newly listed plants, but some plants previously listed as rare retain this designation.
– = no listing.

California Native Plant Society (CNPS)

1B = List 1B species: rare, threatened, or endangered in California and elsewhere.
2 = List 2 species: rare, threatened, or endangered in California but more common elsewhere.
3 = List 3 species: more information is needed about this plant
4 = List 4 species: limited distribution and on a watch list.
0.1 = seriously endangered in California.
0.2 = fairly endangered in California.
* = presumed extirpated from that County.

1

4.10.1.2.6 Tree Resources

Approximately 78 trees were observed during the December 2008 arborist survey and consisted of Goodding's black willow, box elder, interior live oak (*Quercus wislizeni*), coast live oak (*Quercus agrifolia*), Fremont cottonwood, Oregon ash, catalpa (*Catalpa* sp.), and valley oak. The results of the December 2008 arborist survey are shown in Table 4.10-2. None of the trees observed during the arborist survey met the definition of a heritage or landmark tree as defined in the City's Tree Preservation Ordinance. Trees located outside of the area that was covered during the 2008 arborist survey consist of scattered individual trees and trees that comprise the small patch of Great Valley mixed riparian forest located at the west end of the study area. Although none of them appear to meet the City's definition of a heritage or landmark tree, they have not been surveyed and have the potential to be protected under the City's Tree Preservation Ordinance.

Table 4.10-2. Arborist Survey Results for CHP Academy EIP

Tree Species	Number of Individuals Observed
Goodding's black willow	16
Box elder	4
Interior live oak	22
Coast live oak	1
Fremont cottonwood	11
Oregon ash	3
Catalpa	2
Valley oak	19

4.10.1.2.7 Invasive Plant Species

Plant species that are considered invasive by the California Department of Agriculture and the California Invasive Plant Council are well-represented and fairly widespread throughout the study area (California Invasive Plant Council 2006, 2007; California Department of Agriculture 2009). Invasive plant species that were observed in the study area during the field visits were Himalayan blackberry, perennial pepperweed, yellow star-thistle, Bermuda grass, Mediterranean mustard, and ripgut brome. The California Department of Food and Agriculture and California Invasive Plant Council ratings for the invasive species observed during the site visits are provided in the plant list for the study area are in Appendix F.

4.10.2 Environmental Consequences

This section describes the environmental consequences relating to vegetation and wetlands for the proposed CHP Academy EIP. It describes the methods used to determine the effects of the project and lists the thresholds used to conclude whether an effect would be significant. The effects that would result from implementation of the CHP Academy EIP, findings with or without mitigation, and applicable mitigation measures are presented in a summary table. These effects tier from the program analysis effects described in Section 3.8.3.3, Effects and Mitigation Measures.

4.10.2.1 Assessment Methods

Evaluation of the vegetation and wetland effects in this section is based on the information provided by technical maps, reports, and other documents that describe the resource conditions of the study area. This information was then compared to the type and location of proposed flood and recreation alternatives to determine whether effects would occur.

4.10.2.2 Determination of Effects

For this analysis, based on professional practice and State CEQA Guidelines Appendix G (14 CCR 15000 *et seq*.), an effect pertaining to vegetation and wetlands was considered an adverse effect under NEPA and a significant impact under CEQA if it would:

- have a substantial adverse effect, either directly or through habitat modification, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations or by DFG or USFWS;
- have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, or regulations, or by DFG or USFWS;
- have a substantial adverse effect on federally protected wetlands as defined by CWA Section 404 (including, but not limited to, marshes and vernal pools) through direct removal, filling, hydrological interruption, or other means;
- conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance; or
- conflict with the provisions of an adopted habitat conservation plan, natural communities conservation plan, or other approved local, regional, or state habitat conservation plan.

4.10.2.2.1 Effect Assumptions

The following assumptions regarding project effects on vegetation and wetlands in the CHP Academy study area have been made for this analysis.

- No special-status plants occur in the study area and therefore effects on special-status plant species are not discussed in this section.
- No landmark or heritage trees occur in the study area and therefore effects on protected trees are not discussed in this section.
- Other than minor trimming, no direct effects on Great Valley mixed riparian forest would occur as a result of implementation of the proposed project alternatives.
- No trees located behind the fence of the adjacent CHP Academy property would be removed.
- All project activities, including equipment staging and access, would take place only within the project disturbance footprint and noted staging areas.
- The project would comply with the USACE vegetation-free policy (i.e., no vegetation is permitted within the levee's operation and maintenance zone, which includes the levee itself and an area extending 15 feet from the landside and waterside toes).
- Fill or borrow material would be obtained from a quarry or other authorized location.

- There would be effects related to the routine operation or maintenance activities under the proposed project. WSAFCA would continue with the authorized levee maintenance actions that are currently used on the Sacramento Bypass Levee. Maintenance of the relief wells (proposed under Alternative B) and lateral drainage system would be performed from maintenance roads.
- If discharge of fill into waters of the United States is associated with the proposed project, WSAFCA would require a CWA Section 404 permit from the USACE Sacramento District, and CWA Section 401 certification from the Central Valley RWQCB. Before construction begins, WSAFCA would obtain all necessary permits pertaining to affected waters of the United States. The permitting process would also require compensation for construction-, operation-, and maintenance-related effects.
- Grading would require a CWA Section 402 permit and preparation of a SWPPP.
- Grading or other construction activities would require a streambed alteration agreement from DFG.

4.10.2.2.2 Effect Mechanisms

Vegetation and wetland resources could be directly and indirectly affected by the proposed project. The following types of activities could cause varying degrees of effects on these resources:

- grading, and fill placement during construction of levee alternatives;
- channel dewatering or installation of temporary water-diversion structures;
- temporary stockpiling and sidecasting of soil, construction materials, or other construction wastes;
- soil compaction, dust, and water runoff from the construction site into adjacent areas;
- introduction or spread of invasive plant species into adjacent open space areas; and
- runoff of herbicides, fertilizers, diesel fuel, gasoline, oil, raw concrete, or other toxic materials used for levee alternatives, operations, and maintenance into sensitive biological resource areas (e.g., riparian habitat, wetlands).

4.10.3 Effects and Mitigation Measures

4.10.3.1 No Action Alternative

The No Action Alternative represents the continuation of existing deficiencies along the portion of the Sacramento Bypass Levee reach in the CHP Academy EIP project area. No levee improvements would be made to increase the level of protection. No construction-related effects on vegetation, such as disturbance of special-status plant species or wetlands would occur.

Because no levee improvements would be made under the No Action Alternative, the risk that the Sacramento Bypass Levee could fail due to seepage or slope stability/geometry issues would continue. Failure of the Sacramento Bypass Levee, depending on the magnitude of the event, could cause catastrophic flooding of the entire city of the magnitude described in the programmatic Vegetation and Wetlands analysis (Section 3.8.3.3.1). In summary, these effects could include significant loss of vegetation and habitat quality due to both the hydraulic forces of the flood itself as

well as the clean-up efforts. However, given the uncertainty of the occurrence or magnitude of such an event, potential effects on vegetation and waters of the United States cannot be fully quantified based on available information.

Little to no vegetation will be removed at this EIP site to comply with the USACE vegetation policy as there is very little woody vegetation within the specified corridor. No effects on vegetation are anticipated in relation to implementation of the Corps' vegetation guidelines under the No Action Alternative.

4.10.3.2 CHP Academy Applicant Preferred Alternative

Implementation of the CHP Academy APA would result in the following effects on vegetation and wetlands. A description of these effects is provided below the summary table.

Effect	Finding	With Mitigation	Mitigation Measure
VEG-3: Disturbance or Removal of Riparian Habitat as a Result of Project Construction	Significant	Less than significant	VEG-MM-1: Compensate for the Loss of Woody Riparian Habitat VEG-MM-4: Conduct Mandatory Contractor/Worker Awareness Training for Construction Personnel VEG-MM-5: Install Construction Barrier Fencing to Protect Sensitive Biological Resources Adjacent to the Construction Zone VEG-MM-6: Retain a Biological Monitor
VEG-4: Loss of Wetlands and Waters of the United States as a Result of Program Construction	Significant	Less than significant	VEG-MM-4: Conduct Mandatory Contractor/Worker Awareness Training for Construction Personnel VEG-MM-5: Install Construction Barrier Fencing to Protect Sensitive Biological Resources Adjacent to the Construction Zone VEG-MM-6: Retain a Biological Monitor
VEG-5: Disturbance or Removal of Protected Trees as a Result of Program Construction	Significant	Less than significant	VEG-MM-4: Conduct Mandatory Contractor/Worker Awareness Training for Construction Personnel VEG-MM-5: Install Construction Barrier Fencing to Protect Sensitive Biological Resources Adjacent to the Construction Zone VEG-MM-6: Retain a Biological Monitor VEG-MM-7: Redesign Proposed Projects to Avoid and Minimize Effects on Sensitive Biological Resources VEG-MM-9: Conduct a Tree Survey VEG-MM-10: Compensate for Loss of Protected Trees
VEG-6: Introduction or Spread of Invasive Plants as a Result of Program Construction	Less than significant	N/A	N/A

The following detail for Effects VEG-3, VEG-4, and VEG-5 is specific to The CHP Academy APA.

Effect VEG-3: Disturbance or Removal of Riparian Habitat as a Result of Project Construction

With the exception of minor trimming, no direct effects on the 0.03 acre of Great Valley mixed riparian forest would occur as a result of the proposed project; however, construction activities associated with the proposed project could potentially result in the disturbance of the Great Valley mixed riparian forest located adjacent to the project disturbance footprint (i.e., construction zone). This effect is potentially significant because the proposed project could have a significant effect on a sensitive natural community. Implementation of mitigation measures VEG-MM-1, VEG-MM-4, VEG-MM-5, and VEG-MM-6 would ensure that the proposed project would not have a significant effect on the Great Valley mixed riparian forest in the study area.

Mitigation

Mitigation Measure VEG-MM-1: Compensate for the Loss of Woody Riparian Habitat

For direct effects on woody riparian habitat that cannot be avoided, WSAFCA will compensate for the loss of riparian habitat to ensure no net loss of habitat functions and values. Compensation ratios will be based on site-specific information and determined through coordination with the appropriate state and Federal agencies during the permitting process (e.g, 2:1=2 acres restored/created/enhanced or credits purchased for every 1 acre removed. Compensation may be a combination of off-site restoration or mitigation credits. WSAFCA will develop a restoration and monitoring plan that describes how riparian habitat will be enhanced or recreated and monitored over a minimum period of time, as determined by the appropriate state and Federal agencies.

If WSAFCA identifies on-site areas (adjacent to the levees) that are outside the USACE vegetation-free zone and chooses to compensate on site or in the project vicinity, a revegetation plan will be prepared. The revegetation plan will be developed prior to the removal of existing riparian vegetation and will be conducted on site or in the project vicinity to the extent feasible; however, mitigation site selection will avoid areas where future levee alternatives or maintenance is likely.

The revegetation plan will be prepared by a qualified restoration ecologist and reviewed by the appropriate agencies. The revegetation plan will specify the planting stock appropriate for each riparian land cover type and each mitigation site, ensuring the use of genetic stock from the project area. The plan will employ the most successful techniques available at the time of planting. Success criteria will be established as part of the plan. Plantings will be maintained for a minimum of 5 years, including weed removal, irrigation, and herbivory protection.

WSAFCA will monitor the plantings annually for 4 years, followed by monitoring every 2 years for the next 6 years to ensure that the plantings have established successfully. WSAFCA will submit annual monitoring reports of survival to the regulatory agencies issuing permits related to habitat effects, including DFG, USACE, NMFS, and USFWS. Replanting will be necessary if success criteria are not met. The riparian habitat mitigation will be considered successful when the sapling trees established meet the success criteria, the habitat no longer requires active management, and vegetation is arranged in groups that, when mature, replicate the area, natural structure, and species composition of similar riparian habitats in the region.

Mitigation Measure VEG-MM-4: Conduct Mandatory Contractor/Worker Awareness Training for Construction Personnel

Before any work occurs in the project area, including grading, a qualified biologist will conduct mandatory contractor/worker awareness training for construction personnel. The awareness training will be provided to all construction personnel to brief them on the need to avoid effects on sensitive biological resources (e.g., riparian habitat, special-status species, special-status wildlife habitat) and the penalties for not complying with permit requirements. The biologist will inform all construction personnel about the life history of special-status species with potential for occurrence on site, the importance of maintaining habitat, and the terms and conditions of the biological opinion or other authorizing document. Proof of this instruction will be submitted to USFWS, DFG, or other overseeing agency, as appropriate.

The training will also cover the restrictions and guidelines that must be followed by all construction personnel to reduce or avoid effects on special-status species during project construction. The crew foreman will be responsible for ensuring that crew members adhere to the guidelines and restrictions. Educational training will be conducted for new personnel as they are brought on the job during the construction period. General restrictions and guidelines for vegetation and wildlife that must be followed by construction personnel are listed below.

- Project-related vehicles will observe the posted speed limit on hard-surfaced roads and a 10-mile-per-hour speed limit on unpaved roads during travel in the project site.
- Project-related vehicles and construction equipment will restrict off-road travel to the designated construction area.
- All food-related trash will be disposed of in closed containers and removed from the study area at least once a week during the construction period. Construction personnel will not feed or otherwise attract fish or wildlife to the project site.
- No pets or firearms will be allowed in the project site.
- To prevent possible resource damage from hazardous materials such as motor oil or gasoline, construction personnel will not service vehicles or construction equipment outside designated staging areas.

For special-status wildlife, any worker who inadvertently injures or kills a special-status wildlife species or finds one dead, injured, or entrapped will immediately report the incident to the biological monitor. The monitor will immediately notify WSAFCA, who will provide verbal notification to the USFWS Endangered Species Office or the local DFG warden or biologist within 3 working days. WSAFCA will follow up with written notification to USFWS or DFG within 5 working days.

Mitigation Measure VEG-MM-5: Install Construction Barrier Fencing to Protect Sensitive Biological Resources Adjacent to the Construction Zone

The construction specifications will require that WSAFCA retain a qualified biologist to identify sensitive biological resources (e.g., special-status species, riparian habitat, wetlands, elderberry shrubs) adjacent to the construction zone that are to be avoided during construction. Sensitive biological resources located adjacent to the directly affected area required for construction, including staging and access, will be fenced off to avoid disturbance in these areas. If necessary, concrete barriers will also be installed to protect sensitive biological resources in areas adjacent to the directly affected area.

Before construction, the contractor will work with the project engineer and a resource specialist to identify the locations for the barrier fencing (and, if necessary, concrete barriers) and will place stakes around the sensitive biological resources to indicate their locations. The protected area will be clearly identified on the construction specifications. The fencing will be installed at least 20 feet from each sensitive biological resource and will be in place before construction activities are initiated. The fencing will be maintained by WSAFCA or its contractor throughout the duration of the construction period. If the fencing is removed, damaged, or otherwise compromised during the construction period, construction activities will cease until the fencing is replaced.

Mitigation Measure VEG-MM-6: Retain a Biological Monitor

WSAFCA will retain qualified biologists to monitor construction activities adjacent to sensitive biological resources (e.g., special-status species, riparian habitat, wetlands, elderberry shrubs). The biologists will assist the construction crew, as needed, to comply with all program implementation restrictions and guidelines. In addition, the biologists will be responsible for ensuring that the program proponent or its contractors maintain the construction barrier fencing adjacent to sensitive biological resources.

Effect VEG-4: Loss of Wetlands and Waters of the United States as a Result of Program Construction

Although the depressional wetland (2.96 acres), pond (0.16 acre), canal (0.11 acre), and drainage ditch (0.05 acre) are located outside the construction zone, ground disturbance associated with the construction of the two levee deficiency treatments could potentially result in the placement of fill materials into one or all of these features. This effect is potentially significant because if fill materials enter the depressional wetland, the proposed project would have adverse significant effect on a sensitive natural community that was interpreted to be a federally protected wetland under the preliminary jurisdictional determination approach. Although the drainage ditch is not considered a sensitive natural community and is not a wetland, it was also interpreted to be a water of the United States under the preliminary jurisdictional determination approach and is therefore also subject to USACE regulation under CWA. Implementation of mitigation measures VEG-MM-4, VEG-MM-5, and VEG-MM-6, described above, would ensure that the CHP Academy APA would not have adverse significant effect on the depressional wetland, pond, canal, or drainage ditch.

Effect VEG-5: Disturbance or Removal of Protected Trees as a Result of Program Construction

Although the trees located outside the CHP Academy EIP project area boundary do not appear to meet the definition of heritage or landmark trees, they have not been formally surveyed and therefore still have the potential to be protected under the City's Tree Preservation Ordinance. With the exception of the small portion of the canopy of the Great Valley mixed riparian forest (discussed under Effect CHP-VEG-1), these trees are located outside the construction zone. However, ground disturbance associated with the construction of the two levee deficiency treatments could potentially result in the disturbance of protected trees. Implementation of program mitigation measures VEG-MM-4, VEG-MM-5, VEG-MM-6, described above, and VEG-MM-7, VEG-MM-9, and VEG-MM-10, below, would ensure that CHP Academy APA would not have a significant effect on trees that are potentially protected under the local ordinance.

Mitigation

Mitigation Measure VEG-MM-7: Redesign Proposed Projects to Avoid and Minimize Effects on Sensitive Biological Resources

WSAFCA will redesign proposed projects to avoid and minimize effects on sensitive biological resources (e.g., riparian areas outside the USACE woody vegetation-free zones, wetlands, protected trees).

Mitigation Measure VEG-MM-9: Conduct a Tree Survey

WSAFCA will retain a certified arborist to conduct a tree survey to identify protected trees in the study area. The arborist will document the results of the tree survey in a report that includes the location, species, size (diameter at breast height), overall health, and dripline diameter of the trees. If the arborist's survey does not identify any protected trees that would be removed or damaged as a result of the proposed program, no additional mitigation would be necessary. If protected trees are present, WSAFCA will implement Mitigation Measure VEG-MM-10.

Mitigation Measure VEG-MM-10: Compensate for Loss of Protected Trees

WSAFCA will apply for a tree permit for the removal of any protected trees during construction. WSAFCA will replace trees that must be removed with trees at or near the location of the effect or another location within West Sacramento approved by the City's tree administrator. WSAFCA will also replace the replacement tree if it dies within 3 years of the initial planting. Replacement is not required if a tree is removed because it poses a risk, hosts a plant parasite, or is otherwise an undesirable species or specimen at the discretion of the City's tree administrator.

Replacement trees are required at a ratio of 1:1 (i.e., 1-inch diameter of replacement plant for every 1-inch diameter of tree removed). Trees may also be mitigated through payment of an in-lieu fee, which will be used to purchase and plant trees elsewhere in West Sacramento. Mitigation will be subject to approval by the City's tree administrator and may consider species affected, replacement species, location, health and vigor, habitat value, and other factors to determine fair compensation for tree loss.

Effect VEG-6: Introduction or Spread of Invasive Plants as a Result of Program Construction

Invasive plants are already present in the project area. However, construction activities associated with construction could introduce new invasive plants or contribute to the spread of existing invasive plants to un-infested areas outside the project area. Invasive plants or their seeds may be dispersed by construction equipment if appropriate prevention measures are not implemented. The introduction or spread of invasive plants as a result of the proposed project could have a significant effect on sensitive natural communities within and outside the project area by displacing native flora. The implementation of one or more of the BMPs described in the environmental commitment to avoid or minimize the spread or introduction of invasive plant species (described in detail in Section 2.9 of Chapter 2, Alternatives) will ensure that the proposed project would not have a significant effect on sensitive natural communities from the introduction or spread of invasive plants.

4.10.3.3 CHP Academy Alternative B

Implementation of the CHP Academy Alternative B would result in the following effects on vegetation and wetlands. A description of these effects is provided below the summary table.

Effect	Finding	With Mitigation	Mitigation Measure
VEG-3: Disturbance or Removal of Riparian Habitat as a Result of Project Construction	Significant	Less than significant	VEG-MM-1: Compensate for the Loss of Woody Riparian Habitat VEG-MM-4: Conduct Mandatory Contractor/Worker Awareness Training for Construction Personnel VEG-MM-5: Install Construction Barrier Fencing to Protect Sensitive Biological Resources Adjacent to the Construction Zone VEG-MM-6: Retain a Biological Monitor
VEG-4: Loss of Wetlands and Waters of the United States as a Result of Program Construction	Significant	Less than significant	VEG-MM-4: Conduct Mandatory Contractor/Worker Awareness Training for Construction Personnel VEG-MM-5: Install Construction Barrier Fencing to Protect Sensitive Biological Resources Adjacent to the Construction Zone VEG-MM-6: Retain a Biological Monitor
VEG-5: Disturbance or Removal of Protected Trees as a Result of Program Construction	Significant	Less than significant	VEG-MM-4: Conduct Mandatory Contractor/Worker Awareness Training for Construction Personnel VEG-MM-5: Install Construction Barrier Fencing to Protect Sensitive Biological Resources Adjacent to the Construction Zone VEG-MM-6: Retain a Biological Monitor VEG-MM-7: Redesign Proposed Projects to Avoid and Minimize Effects on Sensitive Biological Resources VEG-MM-9: Conduct a Tree Survey VEG-MM-10: Compensate for Loss of Protected Trees
VEG-6: Introduction or Spread of Invasive Plants as a Result of Program Construction	Less than significant	N/A	N/A

The following detail for Effects VEG-3, VEG-4, and VEG-5 is specific to The CHP Academy Alternative B:

Effect VEG-3: Disturbance or Removal of Riparian Habitat as a Result of Project Construction

With the exception of minor trimming, no direct effects on the 0.03 acre of Great Valley mixed riparian forest would occur as a result of implementation of CHP Academy Alternative B; however, construction activities associated with CHP Academy Alternative B could potentially result in the disturbance of the Great Valley mixed riparian forest located adjacent to the disturbance footprint (i.e., construction zone). This effect is potentially significant because Alternative B could have a significant effect on a sensitive natural community. Implementation of program mitigation measures VEG-MM-1, VEG-MM-4, VEG-MM-5, and VEG-MM-6, described above under CHP Academy APA,

would ensure that CHP Academy Alternative B would not have a significant effect on the Great Valley mixed riparian forest at the CHP Academy EIP area.

Effect VEG-4: Loss of Wetlands and Waters of the United States as a Result of Program Construction

Although the depressional wetland (2.96 acres), pond (0.16 acre), canal (0.11 acre), and drainage ditch (0.05 acre) are located outside the construction zone, ground disturbance associated with the construction of Alternative B could potentially result in the placement of fill materials into one or all of these features. This effect is potentially significant because if fill materials enter the depressional wetland, the proposed project would have adverse significant effect on a sensitive natural community that was interpreted to be a federally protected wetland under the preliminary jurisdictional determination approach. Although the drainage ditch is not considered a sensitive natural community and is not a wetland, it was also interpreted to be a water of the United States under the preliminary jurisdictional determination approach and is therefore also subject to USACE regulation under CWA. Implementation of program mitigation measures VEG-MM-4, VEG-MM-5, and VEG-MM-6, described above under CHP Academy APA, would ensure that Alternative B would not have a significant effect on the depressional wetland, pond, canal, or drainage ditch.

Effect VEG-5: Disturbance or Removal of Protected Trees as a Result of Program Construction

Although the trees located outside the CHP Academy EIP project area boundary do not appear to meet the definition of heritage or landmark trees, they have not been formally surveyed and therefore still have the potential to be protected under the City's Tree Preservation Ordinance. With the exception of the small portion of the canopy of the Great Valley mixed riparian forest (discussed under Effect CHP-VEG-1), these trees are located outside the construction zone. However, ground disturbance associated with the construction of CHP Academy Alternative B could potentially result in the disturbance of protected trees. Implementation of program mitigation measures VEG-MM-4, VEG-MM-5, VEG-MM-6, VEG-MM-7, VEG-MM-9, and VEG-MM-10, described above under CHP Academy APA, would ensure that CHP Academy Alternative B would not have a significant effect on trees that are potentially protected under the local ordinance.

Effect VEG-6: Introduction or Spread of Invasive Plants as a Result of Program Construction

This effect is the same as described above under CHP Academy APA. This effect is considered less than significant. No mitigation is required.

Section 4.11

Fisheries and Aquatic Resources—CHP Academy Early Implementation Project

4.11.1 Affected Environment

This section describes the affected environment for fisheries and aquatic resources in the CHP Academy EIP project area, including the regulatory and environmental setting.

4.11.1.1 Regulatory Setting

4.11.1.1.1 Federal

The following Federal policies related to fisheries and aquatic resources may apply to implementation of the CHP Academy EIP. Please see the program information in Section 3.9.2.1, Regulatory Setting, for a more complete description of each policy.

- Endangered Species Act
- Clean Water Act
- Magnuson-Stevens Fishery Conservation and Management Act

4.11.1.1.2 State

The following state policies related to fisheries and aquatic resources may apply to implementation of the CHP Academy EIP. Please see the program information in Section 3.9.2.1, Regulatory Setting, for a more complete description of each policy.

- California Endangered Species Act
- California Fish and Game Code Section 1600: Streambed Alteration Agreements

4.11.1.1.3 Local

The following local policies related to fisheries and aquatic resources may apply to implementation of the CHP Academy EIP. Please see the program information in Section 3.9.2.1, Regulatory Setting, for a more complete description of each policy.

- *City of West Sacramento General Plan*
- *Yolo County General Plan*

4.11.1.2 Environmental Setting

4.11.1.2.1 Study Area

The CHP Academy EIP project area is located on the Sacramento Bypass Levee. The Sacramento Bypass Levee has a concrete-lined bank and the channel is floodplain habitat with terrestrial

vegetation. The study area contains 1.16 acres of great valley mixed riparian forest trees; however, there is no SRA present in the study area. The Sacramento Bypass is only flooded in the winter during high flow events.

The Sacramento Bypass provides emigration and rearing habitat for juvenile anadromous fish and spawning and rearing habitat for Sacramento splittail. The occurrence of these life stages in the Sacramento Bypass is limited to periods when flooding (via the Fremont and Sacramento Weirs) allows individuals to access the area from the Sacramento River. Sacramento splittail and juvenile Chinook salmon have been captured in the Sacramento Bypass (Jones & Stokes 2001). Most juveniles emigrate from the Sacramento Bypass during winter and spring before the floodplains become dry. Thus, the potential for these species' life stages to occur in these areas in any given year depends on the occurrence of flooding; the timing, magnitude, and duration of flooding; and the seasonal timing of specific life stages.

4.11.1.2.2 Aquatic Habitat

Aquatic habitat in the CHP Academy project area consists of seasonal habitat characterized as floodplain habitat; which is present in the Sacramento Bypass. As discussed in the Program Environmental Setting, fish and other species use this habitat for growth, survival, and reproduction. Floodplains are important habitat for young fish, especially Chinook salmon and splittail (Moyle et al. 2005: 21) that use inundated floodplain habitats (when available) for rearing. Chinook growth has been shown to be faster in floodplain habitat (Sommer et al. 2001b) and Sacramento splittail produce the highest number of young when flows are high and floodplain habitat is inundated (Moyle 2002: 148). Fish may use floodplain habitat differently, depending on species and life stage. Special-status fish species that may use the floodplain habitat within the CHP Academy project area include Chinook salmon, Sacramento splittail, green sturgeon, steelhead, and river lamprey. A description of these species, including their status and life stages, is provided in the Program Area Affected Environment.

4.11.2 Environmental Consequences

This section describes the environmental consequences relating to fisheries and aquatic resources for the proposed CHP Academy EIP. It describes the methods used to determine the effects of the project and lists the thresholds used to conclude whether an effect would be significant. The effects that would result from implementation of the CHP Academy EIP, findings with or without mitigation, and applicable mitigation measures are presented in a summary table. These effects tier from the program analysis effects described in Section 3.9.3.3, Effects and Mitigation Measures.

4.11.2.1 Assessment Methods

To prepare for the field surveys and analysis of the potential effects of the proposed program on fish species, fisheries biologists reviewed existing resource information related to the study area to evaluate whether sensitive habitats and special-status fish species are known from or could occur in the study area. The information reviewed included the following sources:

- a USFWS list of endangered, threatened, and proposed species for the Sacramento West, Clarksburg, Liberty Island, and Rio Vista USGS 7.5-minute quadrangle and Sacramento and Yolo Counties (U.S. Fish and Wildlife Service 2009); and

- published and unpublished documents and reports pertaining to the study area.

A reconnaissance-level survey of the study area was conducted by an ICF International fisheries biologist on October 26, 2007. During the survey, fish habitat was identified and evaluated for its ability to support special-status fish species.

The key effects were identified and evaluated based on the environmental characteristics of the CHP Academy EIP project area and the magnitude, intensity, and duration of activities related to the construction and operation of this project.

4.11.2.2 Determinations of Effects

For this analysis, an effect pertaining to special-status fish species and their habitats was considered adverse under NEPA or significant under CEQA if it would result in any of the following environmental effects, which are based on professional practice and CEQA Guidelines Appendix G (14 CCR 15000 *et seq.).*

Assessment species are selected based on listing under the ESA and/or CESA. An effect was considered adverse under NEPA and significant under CEQA if program actions would substantially reduce the abundance and distribution of the identified important fish species. Additionally, adverse effects/significant impacts may occur if the project alternatives would result in:

- substantial interference with the movement of any resident or migratory fish species;
- substantial long- or short-term loss of habitat quality or quantity;
- substantial adverse effects on rare or endangered species, candidate species, other special-status species, or habitat of the species; or
- substantial adverse effects on fish communities or species protected by applicable environmental plans and goals.

4.11.2.2.1 Effect Assumptions

The determination of significance requires that:

- environmental conditions are measurably changed by the project,
- the change in environmental conditions adversely affects a species or its habitat,
- the change in environmental conditions is permanent or ongoing or affects a substantial proportion of the species population, or
- species population abundance is likely reduced, including a short-term reduction.

4.11.2.2.2 Effect Mechanisms

The assessment of effects considers the occurrence and potential occurrence of species and life stages relative to the magnitude, timing, frequency, and duration of program activities. Species habitat attributes potentially affected by construction activities include rearing habitat area and migration habitat conditions. Short-term effects on fish species attributable to bank protection activities include water quality effects and noise and disturbance. Long-term effects on fish habitat include loss of aquatic vegetation and SRA cover. This evaluation of effects on special-status fish species was based on the analysis of the proposed levee treatments.

Short-term construction effects are evaluated qualitatively based on general knowledge of the physiological tolerances and behavioral responses of listed fish species to potential increases in turbidity and suspended sediment, noise, and contaminants.

4.11.3 Effects and Mitigation Measures

4.11.3.1 No Action Alternative

The No Action Alternative would consist of the continuation of the existing deficiencies along the portion of the Sacramento Bypass Levee reach encompassed by the CHP Academy site (i.e., no levee improvements would be implemented to meet the minimum level of acceptable flood protection). Current levee operations and maintenance activities would continue. No construction-related release of contaminants would occur, and no noise and disturbance to special-status fish species or construction-related loss of habitat for special-status fish species would occur. The current levee maintenance activities, including mowing and application of herbicides, would continue.

Because no levee improvements would be made under the No Action Alternative, the risk that the Sacramento Bypass Levee could fail due to seepage or slope stability/geometry issues would continue. Failure of the Sacramento Bypass Levee, depending on the magnitude of the event, could cause catastrophic flooding of the magnitude described in the Fisheries and Aquatics program analysis (Section 3.9.3.3.1). In summary, those effects could result in the displacement of fish into flooded areas and the potential for stranding and mortality. In addition, significant water quality effects could result from the release of hazardous materials during a flooding event, which could lead to stress and direct mortality or significantly affect migration, spawning and rearing habitat of fish species. Emergency clean-up and earth-moving activities could also result in an increase in sediment and turbidity and the release of hazardous materials into the Sacramento Bypass, Yolo Bypass, Delta, and adjacent waterways that significantly affect migration, spawning or rearing habitat, or result in direct mortality of special status fish species. Given the unpredictable nature of emergency clean-up activities, is it likely that implementation of BMPs and measures to reduce effects on fish would not be possible. All of these effects would be considered significant.

4.11.3.2 CHP Academy Applicant Preferred Alternative

Implementation of the CHP Academy APA would result in the following effect on fisheries and aquatic resources. A description of the effect is provided below the summary table.

Effect	Finding	With Mitigation	Mitigation Measure
FISH-12: Temporary Effects on Seasonal Floodplain Habitat for Special-Status Fish	Less than significant	N/A	

Effect FISH-12: Temporary Effects on Seasonal Floodplain Habitat for Special-Status Fish

When the Sacramento bypass is inundated with seasonal flood flows, it can provide seasonal floodplain habitat for special status fish species such as juvenile Chinook salmon (for rearing) and by Sacramento splittail (for spawning and rearing). Green sturgeon and delta smelt may also use

floodplain habitat during migration. Any effects on floodplain habitat as a result of the proposed project would be temporary and primarily related to construction activities. Post-construction, any disturbed areas would be hydroseeded to provide reestablishment of vegetation. Effects on fish would be less than significant because construction would be limited to the typical construction season and outside the principal spawning and migration season. The typical construction season generally corresponds to the dry season, but, if necessary, WSLIP construction may occur outside the limits of the dry season. Construction outside the typical dry season would likely only occur during years when the onset of rains is delayed and conditions are still favorable for construction activities to continue without adverse environmental effects and only as allowed by applicable permit conditions or consultation with NMFS.

4.11.3.3 CHP Academy Alternative B

Implementation of the CHP Academy Alternative B would result in the following effect on fisheries and aquatic resources. A description of the effect is provided below the summary table.

Effect	Finding	With Mitigation	Mitigation Measure
FISH-12: Temporary Effects on Seasonal Floodplain Habitat for Special-Status Fish	Less than significant	N/A	

Effect FISH-12: Temporary Effects on Seasonal Floodplain Habitat for Special-Status Fish

Construction of a stability berm, interior drain, and relief wells would all take place on the landside of the levee, making the majority of construction activities occur outside the channel. However, staging areas would still occur within the bypass. Nonetheless, as discussed above under the CHP APA, construction would occur during the dry season and floodplain habitat would be reseeded and restored to its original condition post-construction. Effects on special-status fish or their habitat would be less than significant. No mitigation is required.

Section 4.12
Wildlife—
CHP Academy Early Implementation Project

4.12.1 Affected Environment

This section describes the affected environment for wildlife resources in the CHP Academy EIP project area, including regulatory and environmental setting.

4.12.1.1 Regulatory Setting

4.12.1.1.1 Federal

The following Federal policies related to wildlife resources may apply to the CHP Academy EIP. Please see Section 3.10.2.1, Regulatory Setting, for a more complete description of each policy

- Federal Endangered Species Act
- Section 7: ESA Authorization Process for Federal Actions
- Section 9: ESA Prohibitions
- Migratory Bird Treaty Act
- Fish and Wildlife Coordination Act

4.12.1.1.2 State

- California Endangered Species Act
- California Fish and Game Code

4.12.1.1.3 Local

- *City of West Sacramento General Plan*
- *Yolo County General Plan*

4.12.1.2 Environmental Setting

This section discusses the environmental setting related to wildlife in the study area for the CHP Academy EIP (defined below), including the methods used to evaluate wildlife habitat, a description of existing land cover types in the project study area, identification of waters of the United States (including wetlands), and discussions of the special-status wildlife species that are known to occur in the project region.

4.12.1.2.1 Study Area

The CHP Academy EIP project area is located in West Sacramento in Yolo County. The project area is approximately 6,500 feet in length, encompassing the Sacramento Bypass levee and additional areas

adjacent to the levee required for construction and staging. For the purposes of this section, the wildlife study area consists of the project area plus an approximately 100-foot-wide buffer zone that accounts for potential indirect effects on VELB. The majority of the study area consists of the levee itself. The portion of the Sacramento Bypass Levee in the study area is mostly unvegetated. Landscaped areas located just outside of the levee are associated with the CHP Academy. The Sacramento Bypass Levee is steeply sloped on both sides. The topography of the portion of the study area adjacent to both levees is relatively level. Elevations in the study area range from approximately 15 to 36 feet above mean sea level.

4.12.1.2.2 Field Surveys

Pre-Field Investigation

An ICF Jones & Stokes biologist reviewed CNDDB (2009a, b) and USFWS (2009) species lists and aerial photographs for the study area prior to field surveys.

Reconnaissance-Level Site Visits

An initial general survey of the project area was conducted by ICF Jones & Stokes biologists on November 29, 2007. The survey was conducted by walking around the study area to visually assess potential wildlife resources. Focused surveys of the project area, including an elderberry shrub survey (the host plant for VELB), were conducted by ICF Jones & Stokes biologists on January 9, 2009; February 13, 2009; and August 13, 2009. During all surveys, wildlife habitat uses associated with land cover types were identified, habitats were evaluated for their ability to support special-status wildlife species, and all wildlife species observed were recorded (Table 4.12-1).

Table 4.12-1. List of Wildlife Species Observed in the CHP Academy Study Area

Common Name	Scientific Name
Birds	
Acorn woodpecker	*Melanerpes formicivorus*
American crow	*Corvus brachyrhynchos*
American kestrel	*Falco sparverius*
Black phoebe	*Sayornis nigricans*
Brewer's blackbird	*Euphagus cyanocephalus*
Bushtit	*Psaltriparus minimus*
California towhee	*Pipilo crissalis*
Canada goose	*Branta canadensis*
Dark-eyed junco	*Junco hyemalis*
European starling	*Sturnus vulgaris*
Golden-crowned sparrow	*Zonotrichia atricapilla*
Great blue heron	*Ardea herodias*
Great egret	*Ardea alba*
House sparrow	*Passer domesticus*
Killdeer	*Charadrius vociferus*
Mallard	*Anas platyrhynchos*
Mourning dove	*Zenaida macroura*

Common Name	Scientific Name
Red-tailed hawk	*Buteo jamaicensis*
Rock dove	*Columba livia*
Spotted towhee	*Pipilo erythrophthalmus*
Swainson's hawk	*Buteo swainsoni*
Turkey vulture	*Cathartes aura*
Western meadow lark	*Sturnella neglecta*
Western scrub jay	*Aphelocoma californica*
White-crowned sparrow	*Zonotrichia leucophrys*
White-tailed kite	*Elanus leucurus*
Yellow-rumped warbler	*Dendroica coronata*

Elderberry Surveys

Elderberry shrub surveys consisted of walking through the project area and mapping, with a sub-meter accurate geographic positioning system (GPS), elderberry shrubs (and shrub clusters) in the proposed flood improvements construction area and within 100 feet in accordance with the USFWS Conservation Guidelines for the VELB (U.S. Fish and Wildlife Service 1999a). Other information recorded for each shrub included number of stems between 1 and 3 inches, 3 and 5 inches, and greater than 5 inches in diameter; whether each stem 1 inch or more in diameter is located in a riparian or non-riparian location; approximate height and width of the elderberry shrub; presence of VELB exit holes; and dominant vegetation that is associated with the elderberry shrub.

4.12.1.2.3 Wildlife Habitat—Land Cover Type Associations

The study area contains the following land cover types: non-native annual grassland, depressional wetland, Great Valley mixed riparian forest, open water, drainage ditch, and developed/landscaped areas. These land cover types are discussed below with respect to the habitat they provide for wildlife. A detailed description of each of these types, including the dominant plants contained within each type, is in Section 3.8, Vegetation and Wetlands. These land cover types are shown in Figure 3.8-3 along with acreages of these types occurring within the construction limit, staging area, and larger study area.

Non-Native Annual Grassland

The majority of the non-native annual grassland in the study area occurs adjacent to the Sacramento Bypass Levee. Non-native grassland in the study area consists of non-native annual grasses, forbs, and scattered shrubs.

Annual grasslands provide nesting and foraging habitat for several species of songbirds, including savanna sparrow (*Passerculus sandwichensis*), white-crowned sparrow (*Zonotrichia leucophrys*), western meadowlark (*Sturnella neglecta*), and foraging habitat for several species of raptors including red-tailed hawk (*Buteo jamaicensis*), white-tailed kite (*Elanus leucurus*), northern harrier (*Circus cyaneus*), great-horned owl(*Bubo virginianus*), and Swainson's hawk (*Buteo swainsoni*). California ground squirrels (*Spermophilus beecheyi*) commonly occur in annual grassland habitat. Their burrows provide important nesting habitat for western burrowing owls (*Athene cunicularia*

hypugea). Reptiles found in these habitats include California king snake (*Lampropeltis getulus californiae*), gopher snake (*Pituophis catenifer*), and western rattle snake (*Crotalus viridis*).

Depressional Wetland

A perennial depressional wetland encompassing approximately 3 acres occurs within the Sacramento Bypass basin portion of the study area. This wetland provides avian foraging opportunities for flycatchers such as western kingbird (*Tyrannus verticalis*) and black phoebe (*Sayornis nigricans*), swallows such as cliff swallow (*Petrochelidon pyrrhonota*), tree swallow (*Tachycineta bicolor*), barn swallow (*Hirundo rustica*), northern rough-winged swallow (*Stelgidopteryx serripennis*), and purple martin (*Progne subis*), waterfowl including mallard (*Anas platyrhynchos*) and ruddy duck (*Oxyura jamaicensis*), other water birds including eared grebe (*Podiceps nigricollis*), and wading birds including great blue heron (*Ardea herodias*), great egret (*Ardea alba*), and snowy egret (*Egretta thula*). The wetland also contains suitable aquatic habitat for reptiles including common garter snake (*Thamnophis sirtalis*), giant garter snake (*Thamnophis gigas*), and western pond turtle (*Actinemys marmorata*) and amphibians including bullfrog (*Rana catesbeiana*), Pacific tree frog (*Hyla regilla*), and western toad (*Bufo boreas*). The wetland does not provide suitable habitat for federally listed vernal pool invertebrates because it is perennial.

Great Valley Mixed Riparian Forest

Great Valley mixed riparian forest occurs adjacent to the depressional wetland within the Sacramento Bypass portion of the study area (Figure 3.8-3). The dominant overstory species are Fremont cottonwood (*Populus fremontii* ssp. *fremontii*), Goodding's black willow (*Salix gooddingii*), and valley oak (*Quercus lobata*). The shrub layer is relatively open and contains small valley oaks, box elder (*Acer negundo* var. *californicum*), and tree tobacco (*Nicotiana glauca*).

Overstory trees may be used for nesting and roosting by numerous raptors, including Swainson's hawk, white-tailed kite, red-tailed hawk, red-shouldered hawk (*Buteo lineatus*), great horned owl, Cooper's hawk (*Accipiter cooperii*), and American kestrel (*Falco sparverius*) as well as by herons and egrets. Other birds that are known to use riparian forests for nesting include Bullock's oriole (*Icterus bullockii*), yellow-rumped warbler (*Dendroica coronata*), tree swallow (*Tachycineta bicolor*), yellow-billed magpie (*Pica nuttalli*), acorn woodpecker (*Melanerpes formicivorus*), northern flicker (*Colaptes auratus*), and western scrub jay (*Aphelocoma californica*). The understory of riparian forests provide habitat for mammals, including various species of rodents, raccoon (*Procyon lotor*), Virginia opossum (*Didelphis virginiana*), and striped skunk (*Mephitis mephitis*). Riparian forests also provide cover and foraging habitat for reptiles and amphibians, such as terrestrial garter snake (*Thamnophis elegans*), California king snake, gopher snake, Pacific tree frog, and western toad. Suitable areas in the understory may also be used as nesting habitat for western pond turtles.

Open Water

Open water areas consist of the canal, which runs perpendicular to the Sacramento Bypass Levee, and the pond just upstream of the canal pump station to the north of the levee. Open water areas contain foraging habitat for birds including swallows and other flycatcher birds, wading birds, and waterfowl. Specific bird species that may utilize these areas for foraging are comparable to those discussed above under the Great Valley mixed riparian forest community. This community also contains suitable aquatic habitat for amphibians and reptiles including bullfrogs, Pacific tree frogs, western toad, common garter snake, giant garter snake, and western pond turtle. Just outside of the

study area small to large patches of freshwater marsh occur in association with these open water areas increasing the overall habitat values and uses of these areas.

Drainage Ditch

A single drainage ditch is located inside the fence around the CHP Academy project area. The drainage ditch appears to drain upland areas between the site and the Sacramento Bypass Levee. The drainage ditch may provide breeding habitat for Pacific tree frogs and western toad.

Levee/Developed/Landscaped Areas

The levee/ developed/landscaped portions of the study area consist of the unvegetated portions of the Sacramento Bypass Levee and developed and landscaped areas in the CHP Academy project area. Unvegetated or developed areas have minimal potential to support wildlife. Landscape trees and shrubs present along the northern boundary of the CHP Academy project area have potential to support nesting of common and special-status birds with potential to nest in riparian forest areas.

4.12.1.2.4 Special-Status Wildlife

Special-status wildlife species are animals that are legally protected under the ESA, CESA, or other regulations and include species that are considered sufficiently rare by the scientific community to qualify for such listing. Special-status species definitions are included above under the Program Environmental Setting section.

Based on the USFWS (2009) list for the quadrangle in the study area and Yolo County, a review of CNDDB (2009a,b) occurrences within a 10-mile radius of the study area, and information collected during field surveys, 35 special-status wildlife species were identified as having potential to occur in the project region (Table 4.12-2). Of these, 22 have low to no potential to occur because the study area is outside the species' known range or suitable habitat is absent from the study area. The remaining 13 wildlife species identified as having potential to occur in the study area include the VELB, giant garter snake, western pond turtle, Swainson's hawk, white-tailed kite, loggerhead shrike, tricolored blackbird, purple martin, northern harrier, western burrowing owl, hoary bat, western red bat, and pallid bat.

The protection status, distributional range, and habitat requirements for these species are described in the Program Environmental Setting section. Information regarding species occurrence within a 10-mile radius of the study area and the suitability of the study area for a particular species is presented below.

Table 4.12-2. Special-Status Wildlife Species with Potential to Occur in the CHP Academy Study Area

Common and Scientific Names	Status Federal/State/ Other	Geographic Distribution	Habitat Requirements	Potential Occurrence in Study Area
Invertebrates				
Delta green ground beetle *Elaphrus viridus*	T/–	Restricted to Olcott Lake and other vernal pools at Jepson Prairie Preserve, Solano County	Sparsely vegetated edges of vernal lakes and pools; occur up to 250 feet from pools	None. Study area is outside of the species' range.
Valley elderberry longhorn beetle *Desmocerus californicus dimorphus*	T/–/–	Stream side habitats below 3,000 feet throughout the Central Valley	Riparian and oak savanna habitats with elderberry shrubs; elderberries are the host plant	High. Known occurrences within a mile of the study area.
Conservancy fairy shrimp *Branchinecta conservatio*	E/–/–	Disjunct occurrences in Solano, Merced, Tehama, Ventura, Butte, and Glenn Counties	Large, deep vernal pools in annual grasslands	None. Study area is outside of the species' range.
Vernal pool fairy shrimp *Branchinecta lynchi*	T/–/–	Central Valley, central and south Coast Ranges from Tehama County to Santa Barbara County. Isolated populations also in Riverside County.	Common in vernal pools; also found in sandstone rock outcrop pools.	None. No suitable habitat in the study area.
Vernal pool tadpole shrimp *Lepidurus packardi*	E/–/–	Shasta County south to Merced County	Vernal pools and ephemeral stock ponds	None. No suitable habitat in the study area.
Lange's metalmark butterfly *Apodemia mormo langei*	E/–/–	Once found throughout the Antioch Dunes; range now reduced to less than 10 acres of Antioch Dunes in Contra Costa County	Limited to dense to moderately dense patches of food plant, wild buckwheat, in stabilized sand dunes	None. Study area is outside of the species' range.
Amphibians				
California tiger salamander *Ambystoma californiense*	T/C/–	Central Valley, including Sierra Nevada foothills, up to approximately 1,000 feet, and coastal region from Butte County south to northeastern San Luis Obispo County.	Small ponds, lakes, or vernal pools in grass-lands and oak woodlands for larvae; rodent burrows, rock crevices, or fallen logs for cover for adults and for summer dormancy	None. No suitable habitat in the study area.

Common and Scientific Names	Status Federal/State/ Other	Geographic Distribution	Habitat Requirements	Potential Occurrence in Study Area
California red-legged frog *Rana aurora draytonii*	T/SSC/–	Found along the coast and coastal mountain ranges of California from Marin County to San Diego County and in the Sierra Nevada from Tehama County to Fresno County	Permanent and semipermanent aquatic habitats, such as creeks and cold-water ponds, with emergent and submergent vegetation. May estivate in rodent burrows or cracks during dry periods.	None. The study area is outside of this species current known range. This species is believed to be extirpated from the valley floor.
Reptiles				
Silvery legless lizard *Anniella pulchra pulchra*	–/SSC/–	Along the Coast, Transverse, and Peninsular Ranges from Contra Costa County to San Diego County with spotty occurrences in the San Joaquin Valley	Habitats with loose soil for burrowing or thick duff or leaf litter; often forages in leaf litter at plant bases; may be found on beaches, sandy washes, and in woodland, chaparral, and riparian areas	Low. No CNDDB occurrences within 10 miles of the study area. Potential habitat in the study area.
Giant garter snake *Thamnophis couchi gigas*	T/T/–	Central Valley from the vicinity of Burrel in Fresno County north to near Chico in Butte County; has been extirpated from areas south of Fresno	Sloughs, canals, low gradient streams and freshwater marsh habitats where there is a prey base of small fish and amphibians; also found in irrigation ditches and rice fields; requires grassy banks and emergent vegetation for basking and areas of high ground protected from flooding during winter	Moderate. CNDDB occurrences 2 miles from study area. Suitable aquatic and upland habitat in the study area.
Western pond turtle *Actinemys marmorata*	–/SSC/–	Occurs from the Oregon border of Del Norte and Siskiyou Counties south along the coast to San Francisco Bay, inland through the Sacramento Valley, and on the western slope of Sierra Nevada	Occupies ponds, marshes, rivers, streams, and irrigation canals with muddy or rocky bottoms and with watercress, cattails, water lilies, or other aquatic vegetation in woodlands, grasslands, and open forests	Moderate. Species observed within ponds 4 miles south of study area along South River Road. Suitable habitat within study area.

Common and Scientific Names	Status Federal/State/ Other	Geographic Distribution	Habitat Requirements	Potential Occurrence in Study Area
Birds				
Double-crested cormorant *Phalacrocorax auritus* (rookery site)	–/SSC/–	Winters along the entire California coast and inland over the Coast Ranges into the Central Valley from Tehama County to Fresno County; a permanent resident along the coast from Monterey County to San Diego County, along the Colorado River, Imperial, Riverside, Kern and King Co.s, and the islands off San Francisco; breeds in Siskiyou, Modoc,Lassen, Shasta, Plumas, and Mon Co.s; also breeds in the San Francisco Bay Area and in Yolo and Sacramento Counties	Rocky coastlines, beaches, inland ponds, and lakes; needs open water for foraging, and nests in riparian forests or on protected islands, usually in snags	Low. No CNDDB nesting records within 10 miles of the study area. No nesting habitat within study area. Sacramento River within study area provides suitable foraging habitat.
White-faced ibis *Plegadis chihi* (rookery site)	–/SSC	Both resident and winter populations on the Salton Sea and in isolated areas in Imperial, San Diego, Ventura, and Fresno Counties; breeds at Honey Lake, Lassen County, at Mendota Wildlife Management Area, Fresno County, and near Woodland, Yolo County.	Prefers freshwater marshes with tules, cattails, and rushes, but may nest in trees and forage in flooded agricultural fields, especially flooded rice fields	Low. No CNDDB nesting records within 10 miles of the study area. No suitable nesting habitat within study area. Grasslands within the Sacramento Bypass provide suitable resting and foraging habitat.
California black rail *Laterallus jamaicensis coturniculus*	–/T/–	Permanent resident in the San Francisco Bay and eastward through the Delta into Sacramento and San Joaquin Counties; small populations in Marin, Santa Cruz, San Luis Obispo, Orange, Riverside, and Imperial Counties.	Tidal salt marshes associated with heavy growth of pickleweed; also occurs in brackish marshes or freshwater marshes at low elevations.	None. No CNDDB nesting records within 10 miles of the study area. No suitable habitat within study area.
California clapper rail *Rallus longirostris obsoletus*	E/E/–	Marshes around the San Francisco Bay and east through the Delta to Suisun Marsh	Restricted to salt marshes and tidal sloughs; usually associated with heavy growth of pickle-weed; feeds on mollusks removed from the mud in sloughs	None. Study area is outside of the species' range.

Common and Scientific Names	Status Federal/State/ Other	Geographic Distribution	Habitat Requirements	Potential Occurrence in Study Area
Mountain plover *Charadrius montanus*	PT/SSC	Does not breed in California; in winter, found in the Central Valley south of Yuba County, along the coast in parts of San Luis Obispo, Santa Barbara, Ventura, and San Diego Counties; parts of Imperial, Riverside, Kern, and Los Angeles Counties	Occupies open plains or rolling hills with short grasses or very sparse vegetation; nearby bodies of water are not needed; may use newly plowed or sprouting grainfields	None. Study area is outside of the species' breeding range, unlikely to forage in study area.
Western snowy plover (inland population) *Charadrius alexandrinus nivosus*	–/SSC	Nests at inland lakes throughout northeastern, central, and southern California, including Mono Lake and Salton Sea	Barren to sparsely vegetated ground at alkaline or saline lakes, reservoirs, ponds and riverine sand bars; also along sewage, salt-evaporation, and agricultural waste-water ponds	None. No suitable nesting or foraging habitat in the study area.
Northern harrier *Circus cyaneus*	–/SSC	Occurs throughout lowland California. Has been recorded in fall at high elevations	Grasslands, meadows, marshes, and seasonal and agricultural wetlands	Moderate. No CNDDB nesting records within 10 miles of the study area. Grasslands within the Sacramento Bypass provide suitable nesting and foraging habitat.
White-tailed kite *Elanus leucurus*	–/ FP/–	Lowland areas west of Sierra Nevada from the head of the Sacramento Valley south, including coastal valleys and foothills to western San Diego County at the Mexico border	Low foothills or valley areas with valley or live oaks, riparian areas, and marshes near open grasslands for foraging	High. CNDDB nesting records within 4 miles of study area. Suitable nesting and foraging habitat in study area.
Swainson's hawk *Buteo swainsoni*	–/T/–/–	Lower Sacramento and San Joaquin Valleys, the Klamath Basin, and Butte Valley. Highest nesting densities occur near Davis and Woodland, Yolo County.	Nests in oaks or cottonwoods in or near riparian habitats. Forages in grasslands, irrigated pastures, and grain fields.	High. CNDDB nesting records within study area.

Common and Scientific Names	Status Federal/State/ Other	Geographic Distribution	Habitat Requirements	Potential Occurrence in Study Area
Western burrowing owl *Athene cunicularia hypugea*	–/SSC/–	Lowlands throughout California, including the Central Valley, northeastern plateau, southeastern deserts, and coastal areas. Rare along south coast	Level, open, dry, heavily grazed or low stature grassland or desert vegetation with available burrows	High. CNDDB nesting records within a mile of the study area. Suitable nesting and foraging habitat in study area.
Western yellow-billed cuckoo *Coccyzus americanus occidentalis*	–/E	Nests along the upper Sacramento, lower Feather, south fork of the Kern, Amargosa, Santa Ana, and Colorado Rivers	Wide, dense riparian forests with a thick understory of willows for nesting; sites with a dominant cottonwood overstory are preferred for foraging; may avoid valley-oak riparian habitats where scrub jays are abundant	None. No suitable nesting habitat in the study area; forests in study area are dominated by valley oak and contain abundant scrub jays.
Loggerhead shrike *Lanius ludovicianus*	–/SSC/–	Resident and winter visitor in lowlands and foothills throughout California; rare on coastal slope north of Mendocino County, occurring only in winter	Prefers open habitats with scattered shrubs, trees, posts, fences, utility lines, or other perches	Moderate. No CNDDB nesting records within 10 miles of the study area. Suitable nesting and foraging habitat in study area.
Tricolored blackbird *Agelaius tricolor*	–/SSC/–	Permanent resident in the Central Valley from Butte County to Kern County; breeds at scattered coastal locations from Marin County south to San Diego County and at scattered locations in Lake, Sonoma, and Solano Counties; rare nester in Siskiyou, Modoc, and Lassen Counties	Nests in dense colonies in emergent marsh vegetation, such as tules and cattails, or upland sites with blackberries, nettles, thistles, and grain fields; habitat must be large enough to support 50 pairs; probably requires water at or near the nesting colony	Moderate. CNDDB nesting records within 3 miles study area. No suitable nesting habitat in study area; suitable foraging habitat in grasslands within the Sacramento Bypass.

Common and Scientific Names	Status Federal/State/ Other	Geographic Distribution	Habitat Requirements	Potential Occurrence in Study Area
Yellow-headed blackbird *Xanthocephalus xanthocephalus*	–/SSC/–	Locally numerous in the Klamath Basin, Modoc Plateau, Great Basin desert, and large mountain valleys in northeastern California; and in the San Joaquin Valley. Common breeders in the Colorado River valley, the Salton Sink, and the western Mojave desert; scarce in the Sacramento Valley and along the southern coast in Los Angeles, Riverside, and San Bernardino counties.	Nest in marshes with tall emergent vegetation, such as tules or cattails, generally in open areas and edges over relatively deep water. Breeding marshes often on edges of deep water bodies such as lakes, reservoirs, and or larger ponds.	None. CNDDB nesting records approximately 10 miles south of the study area. No suitable nesting or foraging habitat in the study area.
Purple martin *Progne subis*	–/SSC/–	Coastal mountains south to San Luis Obispo County, west slope of the Sierra Nevada, and northern Sierra and Cascade ranges. Absent from the Central Valley except in Sacramento. Isolated, local populations in southern California	Nests in abandoned woodpecker holes in oaks, cottonwoods, and other deciduous trees in a variety of wooded and riparian habitats. Also nests in vertical drainage holes under elevated freeways and highway bridges	Moderate. CNDDB nesting records under nearby freeway approximately 5 miles southeast of the study area. Suitable nesting habitat in study area.
Bank swallow *Riparia riparia*	–/T/–	Occurs along the Sacramento River from Shasta County to Sacramento County, along the Feather and lower American Rivers, in the Owens Valley; and in the plains east of the Cascade Range in Modoc, Lassen, and northern Siskiyou Counties. Small populations near the coast from San Francisco County to Monterey County	Nests in bluffs or banks, usually adjacent to water, where the soil consists of sand or sandy loam	Low. CNDDB nesting records approximately 5 miles southeast of the study area. No suitable nesting habitat in the study area.
Saltmarsh common yellowthroat *Geothlypis trichas sinuosa*	–/SSC/–	Found only in the San Francisco Bay Area in Marin, Napa, Sonoma, Solano, San Francisco, San Mateo, Santa Clara, and Alameda Counties	Freshwater marshes in summer and salt or brackish marshes in fall and winter; requires tall grasses, tules, and willow thickets for nesting and cover	None. Study area is outside of the species' range.

Common and Scientific Names	Status Federal/State/ Other	Geographic Distribution	Habitat Requirements	Potential Occurrence in Study Area
Grasshopper sparrow *Ammodramus savannarum*	–/SSC/–	Summer resident in the foothills of the Sierra Nevada and Coast Range from Mendocino and Trinity counties south to San Diego County.	Dry, dense grasslands with a variety of grasses and tall forbs and scattered shrubs.	Low. No CNDDB nesting records within 10 miles of the study area. Low quality nesting habitat within study area.
Suisun song sparrow *Melospiza melodia maxillaris*	–/SSC/–	Restricted to the extreme western edge of the Delta, between the cities of Vallejo and Pittsburg near Suisun Bay	Brackish and tidal marshes supporting cattails, tules, various sedges, and pickleweed	None. Study area is outside of the species' range.
Mammals				
Hoary bat *Lasurius cinerius*	–/SSC/–	Occurs throughout California from sea level to 13,200 feet.	Primarily found in forested habitats. Also found in riparian areas and in park and garden settings in urban areas. Day roosts within foliage of trees.	Moderate. Not reported to occur within study area; reported in CNDDB to occur approximately 2 miles of the study area. Suitable roosting habitat in study area.
Pallid bat *Antrozous pallidus*	–/SSC/FSS, WBWG: High priority	Occurs throughout California except the high Sierra from Shasta to Kern County and the northwest coast, primarily at lower and mid elevations	Occurs in a variety of habitats from desert to coniferous forest. Most closely associated with oak, yellow pine, redwood, and giant sequoia habitats in northern California and oak woodland, grassland, and desert scrub in southern California. Relies heavily on trees for roosts	Moderate. Not reported to occur within study area; no CNDDB record reported to occur within 10 of the study area. Suitable roosting habitat in study area.
Western red bat *Lasiurus blossevillii*	–/–/FSS, WBWG: High priority	Scattered throughout much of California at lower elevations	Found primarily in riparian and wooded habitats. Occurs at least seasonally in urban areas. Day roosts in trees within the foliage. Found in fruit orchards and sycamore riparian habitats in the central valley	Moderate. Not reported to occur within study area; no CNDDB record reported to occur within 10 of the study area. Suitable roosting habitat in study area.
Salt marsh harvest mouse *Reithrodontomys raviventris*	E/E, FP	San Francisco, San Pablo, and Suisun Bays; the Delta	Salt marshes with a dense plant cover of pickle-weed and fat hen; adjacent to an upland site	None. Study area is outside of the species' range.

Common and Scientific Names	Status Federal/State/ Other	Geographic Distribution	Habitat Requirements	Potential Occurrence in Study Area
